Note: Absence of colloidal matter checked (please see below the statement of the contract institute):

There are no observations and related remarks in the lab journal regarding the presence of any colloidal matter in the aqueous extracts derived from the column elution experiments. In the case of the test item alpha-cypermethrin, a presence of colloidal matter in the aqueous fractions is very improbable:

- The water solubility of this analyte is extremely low (approx. 3 µg/L water, as experimentally determined within the study). Colloidal alpha-cypermethrin resulting in a Tyndall effect and generating a visible turbidity of the aqueous fractions would require much higher concentrations of alpha-cypermethrin. Thus, there is no evidence for presence of colloidal alpha-cypermethrin in the aqueous samples.
- If colloidal alpha-cypermethrin would be present in the aqueous fractions, it will be significantly dissolved in the extracts from the column elution experiments after 1:1 dilution with acetonitrile (see sample preparation in section 2.4.3). However, all concentrations of alpha-cypermethrin observed in these fractions were in the low µg/L concentration range excluding the presence of undissolved alpha-cypermethrin in the samples.
- In addition, alpha-cypermethrin present as colloidal material would be significantly eliminated from the aqueous fractions by filtering through the polyethylene frits present in the SPE reservoirs used in the experiments (see section 2.4.2 of the report).

Table of Contents

CA 3 FURTHER INFORMATION ON THE ACTIVE SUBSTANCE

CA 3.1 Use of the Active Substance

Alpha-cypermethrin exhibits high levels of efficacy on a broad range of crop-relevant noxious insects at dose rates between 10 to 30 g ai/ha. The proposed use of the active is accordingly as a foliar-applied agricultural / horticultural insecticide for the control of a range of sucking and chewing pests in a variety of crops.

CA 3.2 Function

Alpha-cypermethrin is used as an insecticide.

CA 3.3 Effects on Harmful Organisms

Alpha-cypermethrin acts as a broad-spectrum insecticide with efficacy against chewing/biting and piercing/sucking insect pests in many agricultural and horticultural crops. Independent from the crop growth-stage or specific cultivation systems, applications are made as foliar sprays in order to control relevant phyto-phagous insect pests which have exceeded economical threshold.

CA 3.4 Field of Use Envisaged

Alpha-cypermethrin is used in horticulture and agriculture as insecticide in order to protect the relevant crop against the attack of plant-destructive insects and so to prevent quantitative and qualitative losses.

CA 3.5 Harmful Organisms Controlled and Crops or Products Protected or Treated

Alpa-cypermethrin is used for the control of most important crop-infesting insect species of the out of the groups of Homoptera, Heteroptera, Lepidoptera, Coleoptera, Diptera and Thysanoptera.

The area of use covers a broad range of crops including:

Cereals (Barley, Wheat, Oat, Rye), Maize, Rice, Millet, Linseed, Cotton, Tobacco,
Oilseed Crops (Oilseed Rape, Mustard, Soybeans,)
Beet roots (Sugarbeet, Cichory roots),
Legume Crops used as dry pulses/dry harvest such as beans (field beans), peas (chickpeas, field peas) or used as legume vegetables/fresh harvest such as beans with & without pods (green beans, french beans, snap beans,), peas with & without pods, Alfalfa,
Fruiting vegetables - Solanacea (Tomato, Eggplant, Peppers), Artichoks,
Fruit.Vegetables – Cucurbitacea (Cucumber, Cucurbits, Melon, Pumpkin, Zucchini/Courgette),
Brassica Vegetables (Broccoli, Brussel Sprouts, Cauliflower, Head cabbage, Leafy cabbage, Flowering cabbage, Kohlrabi).
Bulb Vegetables (Onion, Welsh onions, Shallot, Garlic, Chives, Salad onions).
Root & Tuber Vegetables (Carrots, Potato, Horse radish, Turnips, Swedes, Parsnip, Celeriac, Rocket, Scarole),
Stem Vegetables (Leek, Celery, Asparagus, Fennel, Spinach)
Leafy Vegetables & Herbs (Lettuce, Cichory, Dill), Poppy
Biannual / perennial crops:
Berries & Small Fruits (Currants, Raspberries, Strawberries),
Pomefruits (apple, pear, Quince)
Stonefruits (cherry, plums, peaches, apricots),
Citrus, , Olives, Table- and vine grapes.

Following insect pests are controlled with Alpha-cypermethrin in relevant major crops (table 1):

Crops	Key targets	
Apple	*Cydia pomonella*	codling moth
	Aphis pomi	green apple aphid
	Dysaphis plantaginea	rosy apple aphid
	Dysaphis devecta	*leaf-curling aphid*
	Anthonomus pomorum	*apple blossom weevil*
	Hoplocampa testudinea	*apple sawfly*
Citrus	Ceratitis capitata	Mediterranean fruit fly
	Toxoptera aurantiae	black citrus aphid
	Aphis spiraecola	green citrus aphid
Peach	*Grapholita molesta*	oriental peach moth
	Myzus persicae	peach aphid
	Ceratitis capitata	Mediterranean fruit fly
Olive	*Bactrocera oleae*	olive fly
	Preys oleae	olive moth
Grapes	*Eupoecilia ambiguella*	grape berry moth
	Lobesia botrana	vine moth
	Scaphoideus titanus	golden flavescence cicadella
	Empoasca vitis	green leafhopper
Tomatoes	*Heliothis armigera*	bollworm
	Spodoptera sp (armyworms)	armyworms
	Plusia sp	*Plusia sp*
Pepper	*Aphis gossypii*	*cotton aphid*
	Myzus persicae	*green peach aphid*
	Tuta absoluta	*Tuta absoluta* (tomato leafminer)
Leafy veg.	*Plutella maculipennis*	diamond back moth
	Pieris brassicae	cabbage white
	Delia radicum	*cabbage root fly*
	Nasonovia ribisnigri	*lettuce aphid*
	Myzus persicae	*peach aphid*
	Brevicoryne brassicae	*cabbage aphid*
Potatoes	Leptinotarsa decemlineata	Colorado potato beetle
	Macrosiphum euphorbiae, A. nasturtii, Aulacorthum solani,	Several aphids
	Phtorimaea operculella	potato moth

Crops	Key targets	
Cereals	*Rhopalosiphum padi*	*apple grain aphid*
	Metopolophium dirhodum	*rose grain aphid*
	Sitobion avenae	*grain aphid*
	Oscinella frit	frit fly
	Delia coarctata	wheat bulb fly
	Oulema melanopus	cereal leaf beetle
	Agromyza sp	miner flies
	Psammottetix alienus	leafhopper – virus transmission
	Cnephasia pumicana	cereal tortrix moth
	Sitodiplosis mosellana & Contarinia tritici	midges
Cotton	*Heliothis armigera*	tobacco budworm
	Pectinophora gossypiella	pink bollworm
	Aphis gossypii	cotton aphid
OSR	*Ceutorhynchus napi*	cabbage stem weevil
	Ceutorhynchus assimilis	*pod weevil*
	Ceutorhynchus quadridens	*small stem weevil*
	Meligethes aeneus	pollen beetle
	Phyllotreta sp.	cabbage flea beetle
	Psylliodes chrysocephala	cabbage stem flea beetle
	Brevicoryne brassicae	cabbage aphid
	Myzus persicae	green peach aphid
	Athalia rosae	*turnip saw fly*
	Dasineura brassicae	brassica pod midge
Peas	*Acyrtosiphum pisum*	Pea aphid
Beans	*Aphis fabae*	Black bean aphid
Corn	*Diabrotica virgifera*	western corn root worm
	Ostrinia nubilalis	European Corn borer
	Rhopalosiphum padi	apple grain aphid
	Metopolophium dirhodum	rose grain aphid
	Sitobion avenae	grain aphid

CA 3.6 Mode of Action

Alpha-cypermethrin, a synthetic pyrethroid, acts like naturally occurring pyrethrum on the nervous system of insects. The nervous system serves to transmit information in the organism. Stimuli act on sensory receptors which trigger a response. The nerves transmit this response e.g. to muscles where a reaction takes place. Changes in electrical charge to the membranes of the nerve fibres play a decisive role in producing and transmitting responses. In an idle state (resting potential) the nerve fibre membranes are charged with a concentration of Na+ ions, positive on the exterior and negative on the interior. The stimuli cause specific Na+ channels to open through which Na+ ions flow into the interior of the nerve fibres and cause a reversal in the state of charge. A so-called action potential is created along the length of the membrane. In order to be able to receive new stimuli the stimulated areas have to be returned to their idle state. This is achieved by actively transmitting ions and closing the specific Na+ channels. If the Na+ channels opened by the creation of action potentials are kept open by the effect of Alpha-cypermethrin, this leads to a succession of sustained action potentials which destroys the impulse sequence and transmission. The affected insect is thus subject to uncoordinated movements and finally death.

Although Alpha-cypermethrin is highly effective against insects it is not toxic for warm-blooded animals because of its high degree introduction of selectivity in the relevant application quantities. Alpha-cypermethrin is active against both piercing-sucking and chewing insects. The effect is triggered by the insects contact with, or ingestion of the active ingredient. In addition to its effect on mature and immature insects Alpha-cypermethrin has also demonstrated a significant ovicidal effect. The excellent knock-down and residual control of Alpha-cypermethrin products are complemented by a strong repellent effect on pests. Because the effect of Alpha-cypermethrin is increased at lower temperatures, Alpha-cypermethrin products can also ideally be used under cool climatic conditions. Due to low solubility in water and excellent rain-fastness the product is not washed off plant surfaces by rain. This means that a high degree of control can be achieved in unfavorable climatic conditions.

CA 3.7 Information on Occurrence or Possible Occurrence of the Development of Resistance and Appropriate Management Strategies

Preliminary remarks

Structure and headlines of the following text are in accordance with the chapter 'Registration Requirements' from the EPPO-Guideline PP1/213/3.

The term 'resistant insect' can be defined in different ways. The agricultural field definition requires that the resistant population must survive the recommended use rate of the insecticide under normal field conditions. However, the recommended field use rate of an insecticide is subjective, and may vary from region to region depending on the crop, cultural practices, or economics. In addition, the environment (i.e. weather, soil type, growing conditions, stress, etc.) plays a significant role toward the insecticide's efficacy. For marginal cases of resistance, a population that typically survives a recommended field use rate may be controlled by the same rate under greenhouse conditions. From a scientific point of view resistance can be defined as a genetically inherited statistical difference in insecticide responses between two populations of the same species. Even though there is a statistical difference among populations, this does not necessarily mean the most resistant population will survive normal field use rates.

IRAC-Classification of Alpha-cypermethrin

The Insecticide Resistance Action Committee (IRAC) developed a system of classifying insecticides according to their mode of action. This classification system groups insecticides into various categories designated by groups. One of the purposes of this system is to make it easier for farmers and farm advisors to understand which insecticides share the same mode of action without having to know the actual biochemical basis.

The classification system is not based on resistance risk assessment; therefore, different insecticides of the same IRAC-class may have different degrees of risk for developing resistance.

According to the IRAC-classification, Alpha-cypermethrin is in the Group 3 (Sodium channel modulators).

Mechanism of Resistance of Alpha-cypermethrin

Insecticide resistance to synthetic pyrethroids occurs via two main basic mechanisms. The first is modification of the target site, reducing its sensitivity to the insecticide (e.g., the *kdr* gene). The second mechanism involves metabolism or sequestration of the insecticide molecule by various enzymes. This is achieved by increased activity levels of specific esterases mixed function oxidases, glutathione S-transferases or GSTs), or a combination of these enzyme systems. A third mechanism occurs when insects absorb toxins slower than susceptible insects (penetration resistance). And the last recognized resistance mechanism occurs when insects detect or recognize the presence of the insecticide and avoid the toxin (behavioral resistance). Target site resistance and metabolic resistance are overwhelmingly the most important forms of resistance in key economic insect pests. Penetration and behavioral resistance have not been reported in Europe with regards to pyrethroids (and specifically not to alphacypermethrin).

Target site resistance

The common target site resistance to pyrethroids is the knock-down resistance associated with amino acid mutations in the voltage-gated sodium channel (the *kdr* and super-*kdr* genes) conferring nerve insensitivity. Multiple knock-down mutation alleles have been identified in multiple agriculturally important species, such as *Myzus persicae*, *Thrips tabaci*, *Plutella xylostella*, and *Tuta absoluta*, etc. The *kdr* L1014F allele is associated to moderate resistance to pyrethroids and DDT and is the most common *kdr* allele encountered in insects. The *super-kdr* allele is consisted of L1014F and M918T mutations and is associated to higher levels of pyrethroid resistance Target resistance of pyrethroids alpha-subunit sodium channel mutants ($para^{ts1}$ and $para^{ts2}$) in *Drosophila melanogaster* have been shown to have reduced sodium channel numbers on neural membranes, neurophysiological defects, and are 10-30 times more resistant to pyrethroids. Target site resistance to pyrethroids has been associated with deficits in reproductive success suffered by the resistant populations in *Heliothis virescens*.

Metabolic resistance

Metabolic resistance to pyrethroids is achieved by increased activity levels of specific esterases, mixed function oxidases, glutathione S-transferases or GSTs, or a combination of these enzyme systems. For example, metabolic resistance to pyrethroids and carbamates in *Myzus persicae* is due to the overproduction of E4 and/or FE4 carboxylesterases. Resistance to pyrethroids in *Meligethes aeneus* is due to increased cytochrome P450. Studies have shown that a typical characteristic of pyrethroid metabolic resistance is overexpression of detoxification genes at transcription level, resulting in increased protein amounts and enzyme activities that lead to higher level of detoxification. Up-regulated detoxification genes conferring pyrethroid resistance have been identified in different species. Overexpressed CYP9A12 and CYP9A14 from pyrethroid-resistant *Helicoverpa armigera* were confirmed to metabolize pyrethroids; CYP6AY3v2 and CYP6FU1 were significantly overexpressed (16 and 24 folds) in a *Laodelphax striatellus* resistant strain. Metabolic resistance to pyrethroids has been suggested to cause low fecundity in *H. virescens*.

In addition to the mechanisms of resistance described above, it is important to note that additional factors could precipitate a field failure without invoking resistance mechanisms, even when alphacypermethrin is applied correctly in the field. One factor influencing the activity of a pyrethroid is the developmental status of an insect. Certain life stages are more susceptible to pyrethroids. For example, the fifth instar (L5) larvae of *Heliothis virescens* are 130 times less sensitive than the younger second instar (L2) larvae as shown in laboratory tests. Similarly, Soderlund et al. (1983) found *Laphygma frugiperda* L5 stage larvae are 25 times less sensitive than the L2 stage. Controlling insects at the correct life stage is essential. Temperature effects also contribute to the efficacy of certain pyrethroids.

Evidence of Resistance to Alpha-cypermethrin

Inherent risk

Alpha-cypermethrin is a chemically resolved product consisting of two isomers of the eight, which make up cypermethrin (*cis*-isomer of cypermethrin). Alpha-cypermethrin is a fast-acting insecticide that works by either contact or ingestion providing control of insect pests in a wide range of crops including cereals (wheat, barley), potatoes, vegetables and oilseed rape.
Based on factors including genetics, pest life cycle, number of pest generation/year, frequency of insecticide application, etc., there is a risk for resistance development to synthetic insecticides in the Alpha-cypermethrin targeted crops.

Resistance Risk per Crop

Cereals
Aphids are the most serious pests of cereals. These include grain aphid, *Sitobion avenae*, rose-grain aphid, *Metopolophium dirhodum*, oat bird-cherry aphid, *Rhopalosiphum padi*, and corn leaf aphid, *R. maidis*. Aphids can also be important vectors of plant viruses in cereals including Barley Yellow Dwarf Virus, BYDV.
Major insect pests of cereals are controlled by Alpha-cypermethrin. Insecticide resistance risk in aphids may generally be considered high because of their short generation time, the occurrence of multiple generations per year, abundant populations, and documented ability to adapt to insecticides. However, there are reports indicating that in aphids, adverse selection is imposed through poorer winter survival, maladaptive behavior, reduced reproductive fitness, and increased predation and parasitism. There is no resistance reported for those major aphid species listed above.
Therefore, based on more than two decades of pyrethroids use on cereals in Europe with virtually no recorded resistance, it can be concluded that the inherent risk for pyrethroid resistance is low in cereals. Modifiers are therefore not required to reduce the risk of resistance development to an acceptable level.

Potatoes

Alpha-cypermethrin is recommended for controlling of the Colorado potato beetle (CPB), *Leptinotarsa decemlineata*, and aphids in this crop.

In Europe some level of resistance against pyrethroids including Alpha-cypermethrin has been reported for CPB. In Germany an annually increasing tolerance to pyrethroids was observed in areas with extensive insecticide use. Complete control could only be achieved in CPB instars L1-L2 at these locations.

The peach-potato aphid, *Myzus persicae*, the melon aphid *Aphis frangulae*, the buckthorn aphid *Aphis nasturtii*, and potato aphid, *Macrosiphum euphorbiae*, are the most important European aphid species of potatoes.
On a global scale, insecticide resistance is widespread in *M. persicae*. Several forms of resistance to insecticides have been reported for this insect. Products used for control of other pests, occurring simultaneously with *M. persicae*, may further complicate resistance development in this aphid. Fortunately, resistant aphids tend to be less fit and have a reduced ability to survive the winter. As a result, individuals with lower levels of resistance are more common the following spring and these are relatively well controlled with established aphicides (IRAC).

Pyrethroids remain highly effective in the field in many areas, even against populations that show pyrethroid resistance in laboratory bioassays. This might be explained by the initial, transient effects of the compounds via hyperactivity and ataxia causing exposed aphids to fall from the foliage.
In Europe, there is no documented strong and wide spread CPB and peach-potato aphid resistance to Alpha-cypermethrin. Regardless, the inherent risk and abundant documented resistance of these two species to pyrethroids remains high. BASF therefore proposes use of modifiers to reduce the risk to an acceptable level.

Fruiting and leafy vegetables, lettuces

Table 1 shows major and minor insect pests of vegetables in Europe. Aphids are some of the most serious pests of vegetables. Melon-cotton aphid, *Aphis gossypii*, and peach-potato aphid, *M. persicae*, are two of the most economically important aphid pests of vegetables in Europe.

A. gossypii is largely confined to glasshouse vegetable crops in Europe. Resistance to organophosphoates by *A. gossypii* was first reported in 1964 and subsequently to carbamates, pyrethroids, neonicotinoids, and others. A *kdr*-type mechanism of resistance to pyrethroids is known to occur in this species, but its geographical range is unclear. Although resistance of many insecticides was reported in Europe, Alpha-cypermethrin resistance has been reported only from Pakistan.
The currant-lettuce aphid, *Nasonovia ribisnigri*, is a pest of lettuce. Control failures have been reported in Spain and France. Bioassays with nine strains of *N. ribisnigri* collected from lettuce in the UK showed widespread, varied, but overall low levels of resistance to pyrethroids.
Resistance to etofenprox, a non-ester pyrethroid molecule, in cabbage aphid, *Brevicoryne brassicae*, has also been reported in Spain. This species has not been reported as being resistant to Alpha-cypermethrin (IRAC), but it is nonetheless assumed as a result of pyrethroid cross-resistance.

Whiteflies are also important insect pests, especially in greenhouse crop production. The glasshouse whitefly, *Trialeurodes vaporariorum*, has developed resistance to all major insecticide classes, but no report on Alpha-cypermethrin resistance yet. The sweetpotato whitefly, *Bemisia tabaci*, is another whitefly species especially in southern European glasshouses. *B. tabaci* has developed high levels of resistance to pyrethroids and other established modes of action. Resistance in *B. tabaci* to Alpha-cypermethrin has been reported from Greece and China.
Alpha-cypermethrin controls piercing-sucking (e.g., aphids, whiteflies) and chewing Lepidoptera (e.g., armyworms, diamondback moth) insect pests in vegetable crops. The inherent resistance risk associated with *M. persicae*, *A. gossypii*, *T. vaporariorum*, *B. tabaci*, and *Spodoptera* spp. is considered by BASF as being “high” because of short generation times, the occurrence of multiple generations per year, abundant populations, wide range of potential host plants, and documented ability to develop insecticide resistance (IRAC Groups in European countries).

The diamondback moth, *Plutella xylostella*, is an important pest of cole crops in many regions of the world. It is however relatively rare in Europe. This species has a long history of developing resistance to a wide variety of insecticides. It is reported to be resistant to 15 pyrethoid insecticides, however, resistance to Alpha-cypermethrin has not been reported in the EU.

Therefore, in cole crops and kale the inherent risk of pyrethroid resistance for field pest populations is considered as being moderate, and BASF recommends that modifiers should be used to reduce the risk to an acceptable level. For *B. tabaci* however, BASF considers the risk of pyrethroid resistance as high. BASF recommends that efficacy of Alpha-cypermethrin applications against this pest is assessed carefully, and alternative products with different mode of action are used as soon as failures in *B. tabaci* control occur or pyrethroid resistance is considered problematic.

Oilseed Rape

The major and minor insect pests of oilseed rape (OSR) are shown in Table 1. It should be noted that several rape pests are also pests of other *Brassica* crops, therefore, there is always possibility of movement between crops. Information presented in the EPPO guidelines for vegetable brassicas may also have relevance for OSR.

An increasing number of failures in controlling pollen beetle (*Meligethes aeneus*) with pyrethroids has been reported from Denmark, Poland, France and Germany. A reduction in sensitivity in *M. aeneus* has also been observed for Alpha-cypermethrin.
Insecticide Resistance Action Committee (IRAC) pollen beetle resistance monitoring efforts from 2007-2009 show pyrethroid resistant populations dominating in many countries in Europe (Belgium, Czech Republic, France, Germany, Netherlands, Sweden, Switzerland, and Poland). Additional surveys indicate presence of resistant populations in the UK, Finland, Hungary, Russia, Austria, Denmark, Norway, and Lithuania..

Alpha-cypermethrin is recommended for controlling several Coleoptera species including flea beetles, pollen beetles, and stem weevils, all of which are important pests of OSR. Only pollen beetles have been recorded to have Alpha-cypermethrin resistance. Pollen beetle populations should be monitored carefully for resistance issues and only where control levels were reported as sufficient, application of Alpha-cypermethrin should be considered.

Based on the extensive use of Alpha-cypermethrin and other pyrethroids on oilseed rape and the occurrence of control failures in pollen beetles, the inherent risk of pyrethroid resistance development to oilseed rape pests is considered by BASF to be “high”.

Cross Resistance to Alpha-cypermethrin

Cross resistance among insecticides of a same mode MoA is a common phenomenon. A given species found to be resistant to one pyrethroid is often resistant to other pyrethroids. The *kdr* or "knockdown" gene confers resistance to DDT and synthetic pyrethroids. Esterases and mixed function oxidases are known to detoxify a number of organophosphate and carbamate insecticides as well as pyrethroids. For example, cytochrome P450 and esterase confer resistance to organophosphates, organochlorine, carbamates and pyrethroids in *H. virescens*, and *M. persicae*. Esterases conferred fenitrothoin and deltamethrin cross resistance in *Anophelus albimanus*.
Alphacypermethrin and other pyrethroids can therefore be affected by a number of resistance mechanisms, or combinations of these mechanisms.

Sensitivity Data

A database of baseline sensitivity was not developed at the time that Alpha-cypermethrin and other synthetic pyrethroids were developed. However, results of numerous in-house and outside contract field studies with various Alpha-cypermethrin formulations that show high levels of pest control are available. The target species in these studies include many of the high-risk insect pests for resistance development such as *M. persicae*, *R. padi*, *R. maidis*, *M. dirhodum*, other aphids, *L. decemlineata*, and *P. xylostella*. These efficacy trials serve as the best available indication of the susceptibility of target pests in Europe.
Most recently, BASF sponsored a study testing Alpha-cypermethrin against various aphid populations in Italy and Spain. The results showed Alpha-cypermethrin susceptibility variation among species and populations, but most of populations maintained full susceptibility. No major shifts in pest susceptibility or field failures were detected or reported.
The low and acceptable level of resistance risk with field use of Alpha-cypermethrin is best evidenced by nearly two decades of commercial field performance.

Use Pattern (unrestricted use)

The major recommended risk modifiers to minimize the likelihood of the development of pest resistance to Alpha-cypermethrin are:

Cereals:
- maximum two applications/year/pest
- if multiple applications are required, alternate with compounds having different modes of action and no cross-resistance
- do not alternate with products of the same mode of action or those showing cross-resistance

Potato:
- maximum two applications/year/pest
- alternate with compounds with different modes of action and no cross-resistance
- do not alternate with products of the same mode of action or those showing cross-resistance

Cole crops/kale:
- maximum two applications/year/pest
- alternate with compounds having different modes of action and no cross-resistance
- do not alternate with products of the same mode of action or those showing cross-resistance

Oilseed rape:
- maximum two applications/year/pest
- alternate with compounds having different modes of action and no cross-resistance
- do not alternate with products of the same mode of action or those showing cross-resistance

Resistance Risk Assessment of Unrestricted Use Pattern and Acceptability of Resistance Risk

For the last 20 years, Alpha-cypermethrin applications have permitted growers to use the product without restriction for resistance management reasons. Furthermore, other members of the pyrethroid family have been similarly applied with minimal or no restriction of use for resistance management reasons, over the last 30 years. This creates an opportunity to observe the effects of an "unrestricted" use pattern based on historical evidence. The supported "safe use" GAPs for Annex I inclusion are cereals, oilseed rape, cabbage and cucumber/courgettes. Resistance to pyrethroids in these crops in the EU has been reported (based on field failures, laboratory work, or rumors) for *A. gossypii* on vegetables (Greece, UK), *M. persicae* on vegetables (Greece, UK), pollen beetle, *meligethes aeneus* in oilseed rape and *Spodoptera exigua* on vegetables (Spain).

High inherent risk profiles include single-site mode of action, monogenetic resistance, ease of metabolism, short life cycle, high fecundity, widespread distribution, existence of a mechanism that the pest metabolizes a range of pesticides, as well as the existence of cross resistance. Despite these risk factors, resistance development in insect pests found in tropical zones using similar application rates have been much more prone to the development of resistance when compared to temperate zones like Europe. Fewer life cycles and harsher winters appear to select against resistant genotypes, which may contribute to a slow development of insecticide resistance in Europe. Two conclusions are clear. First, reported cases of Alpha-cypermethrin resistance in arthropod species on the intended crops even after three decades of using pyrethroids in Europe are still restricted to four pest species. Secondly, Europe climate and geography appears to contribute to a reduced rate of resistance development when compared to tropical zones.

Implementation of Management Strategy

BASF is founder member of the IRAC Working Group and has participated in forming the guidelines for management strategy.

The basic principles of resistance management are similar in both the prevention of resistance in a given population, as well as in the limitation of resistance after its first occurrence. Once problems have been detected, management strategies have to be adapted to the particular situation. As a rule, the following methods can be recommended:

- Sequences of insecticides with different modes of action
- Crop rotation
- Cultivation practices

BASF promotes further awareness of general aspects of insecticide resistance management in product and technical leaflets, training sessions to sales personnel, distributors and growers' associations. Additionally, specific aspects on the product use are provided for achieving best control results.

Following an example on key elements of the resistance management strategy for FASTAC including general and product specific aspects:

- Always follow IRAC guidelines for preventing and managing insecticide resistant insects.
- Maximise the use of cultural control measures wherever possible
- Use sequences of effective insecticides with different modes of action within individual crops, or successive crops.
- Monitor fields regularly and investigate the reasons for any poor control

Monitoring, Reporting, and Reaction to Changes in Performance

In the case that BASF obtains information about a loss of field performance after application of Alpha-cypermethrin, and that resistance to Alpa-cypermethrin is identified as the cause, BASF will inform IRAC and the registration authorities. Furthermore, BASF will advise the respective farmer to apply the appropriate resistance management strategies as developed and recommended by IRAC. Once resistant strains have been detected, management strategies must be customized to the particular situation under consideration of points of view published by IRAC.

CA 3.8 Methods and Precautions Concerning Handling, Storage, Transport or Fire

Report:	CA 3.8/1 Anonymous, 2016a Safety data sheet – Alpha-Cypermethrin tech-biocide use 2016/1236516
Guidelines:	EEC 1907/2006
GLP:	no

Personal protection: Control parameters

Components with workplace control parameters: No occupational exposure limits known.

Exposure controls

Personal protective equipment

Respiratory protection:
Suitable respiratory protection for lower concentrations or short-term effect: Particle filter with high efficiency for solid and liquid particles (e.g. EN 143 or 149, Type P3 or FFP3).

Hand protection:
Suitable chemical resistant safety gloves (EN 374) also with prolonged, direct contact (Recommended: Protective index 6, corresponding > 480 minutes of permeation time according to EN 374): E.g. nitrile rubber (0.4 mm), chloroprene rubber (0.5 mm), butyl rubber (0.7 mm) and other.

Eye protection:
Safety glasses with side-shields (frame goggles) (e.g. EN 166)

Body protection:
Body protection must be chosen depending on activity and possible exposure, e.g. apron, protecting boots, chemical-protection suit (according to EN 14605 in case of splashes or EN ISO 13982 in case of dust).

General safety and hygiene measures
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Store work-clothing separately. Keep away from food, drink and animal feeding stuffs.

Precautions for safe handling

No special measures necessary if stored and handled correctly. Ensure thorough ventilation of stores and work areas. When using do not eat, drink or smoke. Hands and/or face should be washed before breaks and at the end of the shift. Remove contaminated clothing and protective equipment before entering eating areas.

Protection against fire and explosion:
Avoid dust formation. Dust can form an explosive mixture with air.
Prevent electrostatic charge - sources of ignition should be kept well clear - fire extinguishers should be kept handy.

Conditions for safe storage, including any incompatibilities

Segregate from foods and animal feeds.
Further information on storage conditions: Keep away from heat. Protect from direct sunlight. Protect against moisture.

Storage stability:
Storage duration: 48 Months

Transport

Land transport

ADR

UN number	UN3349

Fire-fighting measures

Extinguishing media

Suitable extinguishing media: water spray, foam, dry powder
Unsuitable extinguishing media for safety reasons: carbon dioxide, water jet

Special hazards arising from the substance or mixture
hydrogen chloride, carbon monoxide, Carbon dioxide, nitrogen oxides, organochloric compounds.
The substances/groups of substances mentioned can be released in case of fire.

Advice for fire-fighters
Special protective equipment:
Wear self-contained breathing apparatus and chemical-protective clothing.

Further information: Collect contaminated extinguishing water separately, do not allow to reach sewage or effluent systems. Dispose of fire debris and contaminated extinguishing water in accordance with official regulations. In case of fire and/or explosion do not breathe fumes. Keep containers cool by spraying with water if exposed to fire.

CA 3.9 Procedures for Destruction or Decontamination

Report:	CA 3.9/1 Anonymous, 2016a Safety data sheet – Alpha-Cypermethrin tech-biocide use 2016/1236516
Guidelines:	EEC 1907/2006
GLP:	no

Waste treatment methods

Must be sent to a suitable incineration plant, observing local regulations.

Contaminated packaging:
Contaminated packaging should be emptied as far as possible and disposed of in the same manner as the substance/product.

Methods and material for containment and cleaning up

For small amounts: Contain with dust binding material and dispose of.

For large amounts: Sweep/shovel up.

Avoid raising dust. Cleaning operations should be carried out only while wearing breathing apparatus. Collect waste in suitable containers, which can be labeled and sealed. Clean contaminated floors and objects thoroughly with water and detergents, observing environmental regulations. Dispose of absorbed material in accordance with regulations.

CA 3.10 Emergency Measures in Case of an Accident

Report:	CA 3.10/1 Anonymous, 2016a Safety data sheet – Alpha-Cypermethrin tech-biocide use 2016/1236516
Guidelines:	EEC 1907/2006
GLP:	no

First-aid measures

Description of first aid measures

First aid personnel should pay attention to their own safety. If the patient is likely to become unconscious, place and transport in stable sideways position (recovery position). Immediately remove contaminated clothing.

If inhaled:
Keep patient calm, remove to fresh air, seek medical attention.

On skin contact:
Immediately wash thoroughly with soap and water, seek medical attention.

On contact with eyes:
Wash affected eyes for at least 15 minutes under running water with eyelids held open.

On ingestion:
Immediately rinse mouth and then drink 200-300 ml of water, seek medical attention.

Most important symptoms and effects, both acute and delayed
Toxic if swallowed; harmful if inhaled (causes temporary irritation after single exposure); repeated oral exposure may affect certain organs (damages the peripheral nerve system).
Please refer to MSDS for further details.

Indication of any immediate medical attention and special treatment needed
Treatment: Treat according to symptoms (decontamination, vital functions), no known specific antidote.

Personal precautions, protective equipment and emergency procedures
Use personal protective clothing. Avoid contact with the skin, eyes and clothing. Avoid dust formation.

Environmental precautions
Do not discharge into the subsoil/soil. Do not discharge into drains/surface waters/groundwater.

Table of Contents

CA 4 ANALYTICAL METHODS

CA 4.1 Methods used for the generation of pre-approval data

CA 4.1.1 Methods for the analysis of the active substance as manufactured

Report: CA 4.1.1/1
Anonymous, 1997a
Determination of Alpha-Cypermethrin in TGAI and WP-, EC-, SC- and UL-formulations
1997/1005661
Guidelines: none
GLP: no

Principle of the method

The active ingredient content in the test samples was determined by means of gas chromatography with a flame ionisation detector and internal calibration according to CIPAC method "ALPHA-CYPERMETHRIN 454". This method contains experimental details regarding sample preparation, chromatographic conditions, evaluation, and calculation.

Applicability of CIPAC Methods

This method corresponds to CIPAC method 454 [Alpha-cypermethrin].

Identity

The identity of the analyte is confirmed by comparison of the retention time with that of authentic reference material and by infrared (IR) spectrometry.

Description of the methods for validation

The validity of the method was confirmed by an international collaborative CIPAC trial. The inter-lab repeatability and inter-lab reproducibility was determined according to ISO 5725.

Data Origin: CIPAC Method 454
Repeatability r: 17 g/kg at 954 g/kg active ingredient content
Reproducibility R: 20 g/kg at 954 g/kg active ingredient content.

The applicability has further been shown in the Analysis Reports of Five Representative Batches of alpha-cypermethrin (see chapter 1.11, confidential part, Document JCA).

For further information on significant impurities, please refer to confidential Document JCA.

CA 4.1.2 Methods for risk assessment

A concordance list of structures and designations of reference compounds mentioned in CA 4.1.2 and 4.2 as well as the respective sections of Doc N is given below.

(a) Methods in soil, water, sediment, air and any additional matrices used in support of environmental fate studies

The following methods cover the compounds that have to be considered for the discussion on environmental risk assessment as summarized in Document N, chapter 8.5 and discussed in CA 7.4:

Soil:	BAS 311 I (cypermethrin, Reg. No. 127266; Cis I, Cis II [alpha-cypermethrin], Trans III, and Trans IV), 3-phenoxybenzoic acid (3-PBA, Reg. No. 130213), 2,2-dimethyl-3-(2,2'-dichlorovinyl)cyclo-propane carboxylic acid (DCVA, cis- and trans-isomers, Reg. No. 180011)
Sediment:	As no aquatic field studies were conducted, no separate stand-alone method validation for the determination of unlabelled alpha-cypermethrin or any of its metabolites was required. Due to similarity to soil matrix, determination of such, if required, can be accomplished by applying the fully validated soil method.
Water:	BAS 311 I (cypermethrin, Reg. No. 127266; Cis I, Cis II [alpha-cypermethrin], Trans III, and Trans IV), 3-phenoxybenzoic acid (3-PBA, Reg. No. 130213), 2,2-dimethyl-3-(2,2'-dichlorovinyl)cyclo-propane carboxylic acid (DCVA, cis- and trans-isomers, Reg. No. 180011), 3-phenoxybenzaldehyde (Reg. No. 4080665)
Air:	BAS 310 I (alpha-cypermethrin, Reg. No. 4078193)

A summary of the methods can be found in the respective section of Doc N, chapter 5.1.3.

Soil

Analytical methods for the determination of alpha-cypermethrin residues in soil were evaluated in the context of the inclusion in Annex I of Directive 91/414/EEC. Methods evaluated previously are listed in Table 4.1.2-1 for the reviewer´s convenience and summarized shortly below.

Table 4.1.2-1: Summary of peer-reviewed analytical methods for determination of alpha-cypermethrin residues in soil

Method No.	Matrix	Method principle	Target analytes	LOQ mg/kg	year	DocID	EU reviewed
SAMS 349-1	Soil	HPLC/UV or GC/ECD after derivatization; TLC/GC or GC/MS for confirmation	DVA	0.05	Issued 1982	AL-230-001 (1983)	Yes
SAMS 348-1	Soil	HPLC/UV; HPLC/UV or GC/MS after derivatization	3-PBA	0.05	Issued 1982	AL-230-001 (1983)	Yes
SAMS 354-2	Soil	GC/ECD; GC/MS for confirmation	Alpha-cypermethrin	0.01	1990	AL-242-001	Yes
SAMS 354-2	Soil	GC/ECD; GC/MS for confirmation	Alpha-cypermethrin	0.05	1999	AL-242-006	Yes
M 3499	soil	sample prep. acc. to SAMS 354-2; GC/MS (confirmatory method)	Alpha-cypermethrin	0.05	2001	AL-210-012	Yes

DVA: 2,2-dimethyl-3-(2,2-dichlorovinyl)cyclopropane carboxylic acid (WL 44776)
3-PBA: 3-phenoxybenzoic acid (WL 44607)

For completeness of information, summaries of already EU-peer reviewed analytical methods are presented for completeness of information.

Report:	CA 4.1.2/1 Hitchings E. et al., 1983 The development of methods for the determination of Ripcord - WL 44776 and WL 44607 in crops and soil AL-230-001
Guidelines:	none
GLP:	No

Principle of the methods SAMS 349-1 and SAMS 349-2:
The methods for both acid metabolites (WL 44776 = 2,2-dimethyl-3-(2,2-dichlorovinyl)cyclopropane carboxylic acid; WL 44607 = 3-phenoxybenzoic acid) are essentially the same.

Soil samples are extracted by tumbling end-over-end with a mixture of acetic acid/water/acetonitrile (1:30:70 v/v), after which the extract is filtered. An aliquot of the filtrate is diluted with water and partitioned under acidic conditions with a diethyl ether/petroleum spirit mixture (1:1 v/v). The organic fraction is concentrated and subsequently cleaned up by normal phase HPLC (LiChrosorb Diol (10 µm); isocratic elution) with UV detection at 225 nm, after which WL 44776 (resp. WL 44607) is determined by reversed phase HPLC (Spherisorb S5 ODS (5 µm); isocratic elution) with UV detection at 216 nm; quantification by external standardization.

If the extracts are not sufficiently clean for satisfactory analysis to be carried out, the acid WL 44776 (as obtained after normal phase HPLC) may be converted into the parent WL 43467 (cypermethrin) by reaction with α-cyano-3-phenoxybenzyl bromide, after which the derivative is cleaned up using a Porasil column. Analysis is then carried out using GC (GE-XE 60 1.2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD).
The acid WL 44607 (as obtained after normal phase HPLC) may be converted into its methyl ester, after which the derivative is cleaned up by partition with petroleum spirit. Analysis is then carried out by either reversed phase HPLC (ODS-Hypersil (5 µm); isocratic elution) with UV detection at 212 nm or GC-MS (SE-30 2% (m/m) on Gas Chrom Q (100-120 mesh)) with multiple ion monitoring (MS operated in EI mode, ions monitored: m/e 196 and 228). The latter procedure may also be adopted to confirm the identity of any residues found.
Residues of WL 44776 determined by HPLC may be confirmed by preparing the parent compound WL 43467 as described above and using either TLC-GC (GE-XE 60 1.2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD) or GC-MS (SE-30 1% (m/m) on Gas Chrom Q (100-120 mesh)) as the determination step, MS operated in EI mode (ions monitored: m/e 207 and 209).

Specificity/Interferences: Typical HPLC chromatograms are shown and from these chromatograms it is clear that control samples show no major interferences at the retention time of WL 44776 or WL 44607; blank values are stated to be < 0.05 mg/kg.
Chromatograms of recovery extracts fortified with WL 44776 and WL 44607 at the same time were not shown, but based on the retention times that were stated, both metabolites should be well resolved under the test conditions used.

Recovery/Precision: see Table **4.1.2-2**

Limit of quantitation*:* The limit of quantitation (LOQ) of the method for both metabolites, defined by the lowest fortification level is 0.10 mg/kg.

Table 4.1.2-2: Validation of methods SAMS 349-01 and SAMS 348-01 (1983/7001072)

		Fortification level (mg/kg commodity)	Number of samples	Range (%)	Mean (%)	RSD (%)
Loam, sandy clay loam	WL 44776 free	0.10	2	75 - 95	85	(16.6)
	WL 44607 free	0.10	2	75 - 80	77.5	(4.6)

Conclusion **The method was developed and validated before SANCO/3029/99 rev. came into force. A newly developed and fully validated method (R0034/01) allows the quantification of the analytes down to 0.001 mg/kg.**

Report:	CA 4.1.2/2 Anonymous, 1990 Determination of residues of Alphacypermethrin in soils - Gas chromatographic method AL-242-001
Guidelines:	none
GLP:	No

Report:	CA 4.1.2/3 Anonymous, 1990 Determination of residues of Alphacypermethrin in soils - Gas chromatographic method AL-242-006
Guidelines:	EEC 91/414,EEC 96/46,BBA Guideline Residue Analytical Methods for Post-Registration Control Purposes of July 21 1998,Guidance Document of Residue Analytical Methods 8064/VI/97 rev. 4 15.12.1998
GLP:	Yes (certified by Umweltministerium Baden-Wuerttemberg, Stuttgart)

Principle of the method:

SAMS 354-02: Soil samples are mixed with anhydrous sodium sulphate and extracted by tumbling end-over-end with acetone/hexane (1:1 v/v). Extracts are washed with water to remove the acetone and cleaned up by liquid-solid chromatography using Florisil.
Alpha-cypermethrin is determined by packed column GC (GE-XE 60 2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD); quantification by external standardization. Confirmation of the residues is carried out by capillary GC-ECD (SE-54; 25m × 0.32 mm, 0.5 µm) and GC-MS (SE-30 1% (m/m) on Gas Chrom Q (100-120 mesh)), MS operated in negative ion chemical ionisation mode (ions monitored: m/e 207 and 209).
It should be noted that a slightly adapted method SAMS 354-02 (incl. i.e. capillary column: DB5, 30m × 0.25 mm, 0.25 µm, temperature program, GC-MS conditions: Optima 5, 25m × 0.25 mm, 0.25 µm) has been validated in the following study by H. Werle (1999) – *Alpha-cypermethrin (CL 900049): Validation of Method SAMS 354-2 for the Determination of Residues in Soils* (BASF DocID 1999/7001540), but the results were not reported in the initial monograph.

Specificity/Interferences *:*	typical packed column GC-ECD chromatograms are shown. Control samples exhibit no significant interfering peaks at the retention time of alpha-cypermethrin; control and blank data were stated to be < 0.01 mg/kg.
Linearity:	Linearity data were not provided for the validation using the packed GC-ECD method but linearity data were presented for the capillary GC-ECD method. Method was found to be linear in the 0.0126 – 0.25 µg/mL. Linearity was checked before sample analysis (n=4), concurrently to analysis (n=3) and at the end of the analysis (n=4). Correlation coefficient R^2 was in each case ≥ 0.997. The regression equations were provided but not the linear curves

Recovery/Precision : see Table **4.1.2-3**

Limit of quantitation: The limit of quantitation (LOQ) of the method for both metabolites, defined by the lowest fortification level is 0.05 mg/kg.

Table 4.1.2-3: Validation of method SAMS 354-02 (AL-242-001, packed GC-ECD and AL-242-006, capillary GC-ECD)

Matrix	Analyte	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
clay loam soil SAMS 354-2 (packed column)	alpha-cypermethrin	0.05 0.20 0.50	2 2 2	100 - 100 90 - 100 105 - 105	100 95 105	(0.0) (7.4) (0.0)

		0.05 - 0.50	18	85 - 115	99.7	9.2
Soil 2.3 (LUFA) SAMS 354-2 (capillary column)	alpha-cypermethrin	0.05 0.5	4* 5	86-123* 83-91	90 87	6.1 3.0

* 123 was identified as an outlier and not taken into account to calculate the mean recovery.

Conclusion **Both methods (packed column and capillary column) are suitable for alpha-cypermethrin residue analysis in soil with a LOQ of 0.05 mg/kg. The method was developed and validated before SANCO/3029/99 rev. came into force. A newly developed and fully validated method (R0034/01) allows the quantification of the analytes down to 0.001 mg/kg.**

Report:	CA 4.1.2/4 Xu B., 2001 BAS 310 I (Alpha-Cypermethrin): Validation of method M 3499 for the confirmation of BAS 310 I residues in water soil and blood by GC/MS
	AL-210-012
Guidelines:	Guidance Document on Residue Analytical Methods (SANCO/825/00rev.6)
GLP:	Yes (certified by United States Environmental Protection Agency)

Principle of the method:
Method M3499 is used to confirm the specificity of Method SAMS 354-2 (GC-ECD), which was proposed for enforcement in soil. The procedure for the sample preparation is the same as the one outlined in SAMS 354-2, but an alternative detection method is used: determination by capillary GC (DB-5MS; 5 m x 0.25 mm i.d; 0.25 µm) with MSD in SIM mode (m/z 207, 209 and 211).

Specificity/Interferences:	specificity of method SAMS 354-2 is demonstrated by using GC-MS as an alternative method of detection (confirmation based on retention times and ion ratios: see Table **4.1.2-4**). - untreated control samples exhibit no significant interferences at retention time of alphacypermethrin (control values < 30% of LOQ).
Linearity:	the response of the GC-MS system (= peak area) to alphacypermethrin was demonstrated to be linear over a concentration range from 0.0025 to 0.04 µg/mL (n = 5); r > 0.99 for each ion. Calibration seems to have been performed in solvent without assessment of the matrix effects.

Recovery/Precision: no data provided; only qualitative validation was performed.

Limit of quantitation:	The limit of quantitation (LOQ) of the method for both metabolites, defined by the lowest fortification level is 0.05 mg/kg.

Table 4.1.2-4: Validation of confirmatory method M 3499 for soil

Analyte	Fortification level (mg/kg commodity)	Number of samples	% Retention Time Difference (RTD) (ion m/z 207)	% Ion Ratio Difference (IRD)	
				207/209	207/211
alphacypermethrin	0.05	3	0.0 0.1 0.0	- 0.6 - 1.0 0.0	- 4.6 - 1.4 - 3.0

% RTD = (sample retention time – average standard retention time) x 100/average standard retention time
% IRD = (sample ion ratio – standard average ion ratio) x 100/standard average ion ratio

Conclusions	**Method M 3499 (GC-MS) is suitable as qualitative confirmatory method to SAMS 354-2 (GC-ECD) for determination of alphacypermethrin residues in soil (LOQ 0.05 mg/kg). A newly developed and fully validated method (R0034/01) allows the quantification of the analytes down to 0.001 mg/kg.**

Report:	CA 4.1.2/5 Carter M.L., Perez S., 2014a Validation of BASF analytical method R0034/01: Method for the quantitation of the diastereomeric forms of BAS 311 I (Reg. 127266) and its metabolites 3-Phenoxybenzoic acid (Reg. No. 130213) and DCVA (cis and trans isomers, Reg. No. 180011) in soil by LC-MS/MS 2014/7002375
Guidelines:	EPA 850.7100, EPA 835.6100, SANCO/3029/99 rev. 4 (11/07/00), SANCO/825/00 rev 8.0 (20/06/2000)
GLP:	yes (certified by United States Environmental Protection Agency)

Principle of the method

The BASF analytical method R0034/01 allows the determination of the diastereomeric forms of BAS 311 I (cypermethrin, Reg. No. 127266; Cis I, Cis II [alpha-cypermethrin], Trans III, and Trans IV), and its three metabolites 3-phenoxybenzoic acid (PBA, Reg. No. 130213) and DCVA (cis- and trans-isomers, Reg. No. 180011) in soil.

Soil samples (5 g) are extracted for cypermethrin isomers (Cis I, Cis II, Trans III, and Trans IV) by shaking with 50 mL of 0.1% formic acid in acetonitrile. An aliquot (20%) from the extract is evaporated to dryness and then re-dissolved with acetonitrile/water with 0.1% formic acid (50:50, v/v). The residues are determined using LC-MS/MS.

Soil samples (5 g) are extracted for the metabolites of cypermethrin (c/s-DCVA, trans-DCVA, and 3-PBA) by shaking twice with 25 mL acetonitrile/water (70:30, v/v). An aliquot (10%) from the combined extract is evaporated to dryness and then dissolved in methanol/water (20:80, v/v) with 0.1% formic acid. The residues are determined using LC-MS/MS.

LC-MS/MS conditions were specifically adapted for the determination of the individual analytes:

Primary and confirmatory mass transitions (*m/z*) for the diastereomeric forms of BAS 311 I (Cis I, Cis II, Trans III, and Trans IV) were analyzed using UPLC and HPLC Methods B and C, respectively.

Primary and confirmatory mass transitions for 3-PBA were analyzed using UPLC and HPLC Methods G and E, respectively. The ions monitored for DCVA (Cis and Trans) were analyzed using UPLC and HPLC Methods G and E, respectively. For DCVA (Cis and Trans), Method E was used for primary quantitation in HPLC mode and confirmatory quantitation for Method G. Additionally, Method F was used for confirmatory quantitation both for HPLC mode and for Method E.

The limit of quantification (LOQ) is 0.001 mg/kg for each analyte, which corresponds to a concentration in the extract of 0.5 ng/mL. The limit of detection in soil is 0.0002 mg/kg (corresponds to 0.1 ng/mL).

Remark: Comparison of extraction recoveries of cypermethrin applying the extraction scheme of the aerobic soil metabolism study and the reported data generation method (M-CA 4.1.2/1) was additionally assessed using ^{14}C-labelled soil samples in the respective soil metabolism study. Details are reported in chapter 7.1.2.1.1 in the respective study: Metabolism of BAS 310 I in soil under aerobic conditions (DocID 2014/1159491).

Recovery findings

The analytical method was developed for the determination of the diastereomeric forms of BAS 311 I (Cis I, Cis II [alpha-cypermethrin], Trans III, and Trans IV), and its three metabolites 3-phenoxybenzoic acid (PBA) and DCVA (cis- and trans-isomers) in soil. The method was validated at two fortification levels (0.001 and 0.01 mg/kg (ppm)) for sandy and clay loam soil samples. For each fortification level and matrix, five replicates were analyzed. Additionally, a method blank and at least two replicates of unfortified samples were examined.

Solvent-based and matrix-matched standards were also analyzed within the study to check for possible matrix effects. Clay and sandy loam soil samples were tested for matrix effects for the diastereomers of BAS 311 I. Clay soil samples were tested for matrix effects for the metabolites of BAS 311 I. No significant suppression (greater than 20%) occurred for any of the analytes when analyzed by LC-MS/MS. If significant suppression occurs, matrix-matched standards may be utilized.

It was proven that the method R0034/01 is suitable to determine residues of the diastereomeric forms of BAS 311 I (cypermethrin, Reg. No. 127266), and its metabolites, 3-phenoxybenzoic acid (Reg. No. 130213), and DCVA (cis- and trans-isomers, Reg. No. 180011) in soil. As shown in the following tables, the mean recovery values were found to be within the acceptable range of 70-120% for all methods tested. The overall relative standard deviations (RSD, %) for all fortification levels were below 20%.

Detailed results of recoveries for each mass transition and soil are given in Table **4.1.2-5** to Table **4.1.2-11**.

Table 4.1.2-5: Recoveries for Cis I, Cis II, Trans III, and Trans IV (Reg. No. 127266) in Sandy Loam Soil Using Method B (UPLC Mode): Primary and Confirmatory Quantitation[a]

Matrix	Fortification Levels (ppm)	n	Recovery (%)	Average Recovery (%)	Standard Deviation	%RSD [b]

Linearity

Good linearity (r > 0.99) was observed in the range of 0.05 to 10 ng/mL (nominal) for the two mass transitions of Cis I, Cis II, Trans III, and Trans IV in mixed standard solutions. Good linearity was observed in the range of 0.1 to 10 ng/mL (nominal) for the two mass transitions of 3-PBA and the one mass transition of cis- and trans-DCVA in mixed standard solutions.

Specificity

The method allows the specific determination of the diastereomeric forms of BAS 311 I (Reg. No. 127266, Cis I, Cis II [alpha-cypermethrin], Trans III, and Trans IV), and its three metabolites 3-phenoxybenzoic acid (Reg. No. 130213, 3-PBA) and DCVA (Reg. No. 180011, cis- and trans-isomers) in soil. Interferences may be observed during analysis of the metabolites of BAS 311 I depending on soil type. This can be alleviated by testing the LC-MS/MS gradient before GLP analysis. Retention time shifting was observed for the diastereomeric forms of BAS 311 I and is instrument dependent. However, this does not affect quantitation as long as the retention pattern is observed and compared with the reference standards. The instrument must be sufficiently conditioned with injections of sample matrix prior to analysis.

Limit of Quantitation The limit of quantitation (LOQ) was defined by the lowest fortification level successfully tested. LOQ is 0.001 mg/kg for each analyte, which corresponds to a concentration in the extract of 0.5 ng/mL. The limit of detection in soil is 0.0002 mg/kg (corresponds to 0.1 ng/mL).

Repeatability The overall relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-5** to Table **4.1.2-11**.

Reproducibility Reproducibility of the method was not determined within this validation study.

Extractability The extractability of the diastereomers of BAS 311 I in soil was tested using the residue and metabolism extraction procedures. An extractability set consisted of one control, two fortifications at the LOQ (0.001 mg/kg for each diastereomer), one fortification at 10 x LOQ (0.01 mg/kg) and one sample with incurred residues from the terrestrial field dissipation study number 380198. Extractability data using the residue and metabolism extraction procedure are presented in Table **4.1.2-12** and Table **4.1.2-13**, respectively. Results show that the diastereomers of BAS 311 I in soil are comparable from both residue and metabolism extraction procedures.

Table 4.1.2-12: Extractability Data using the Residue Extraction Procedure

Matrix	Final Reported ppm			
	Cis I	Cis II	Trans III	Trans IV
Soil	0.0015	0.0052	ND	ND

Table 4.1.2-13: Extractability Data using the Metabolism Extraction Procedure

Matrix	Final Reported ppm			
	Cis I	Cis II	Trans III	Trans IV
Soil	0.0024	0.0033	ND	ND

Standard stability During the method validation, it was found that the calibration standard solutions of BAS 3111 were stable (less than 20% decline) for at least 64 days refrigerated and the fortification and concentrated stock solutions were stable for at least 65 days. The metabolites of BAS 311 I were stable (less than 20%) for at least 38 days for calibration and fortification solutions and at least 69 days for the concentrated stock solution.

Conclusion

The method for analysis of the diastereomeric forms of BAS 311 I (Cis I, Cis II [alpha-cypermethrin], Trans III, and Trans IV), and its three metabolites 3-phenoxybenzoic acid (Reg. No. , PBA) and DCVA (Reg. No. , cis- and trans-isomers) in soil uses LC-MS/MS for final determinations, which is a modern and highly specific technique. The limit of quantitation was 0.001 mg/kg for each analyte.

It was demonstrated that method R0034/01 fulfills the requirements with regard to specificity, repeatability, limit of quantitation, and recoveries and is, therefore, applicable to correctly determine residues of the insecticide BAS 311 I (cypermethrin, Reg. No. 127266) and its metabolites 3-phenoxybenzoic acid (Reg. No. 130213) and DCVA (cis- and trans-isomers, Reg. No. 180011) in soil.

~~**Report:** CA 4.1.2/2~~
~~N.N.~~
~~Determination of metabolite M310I017 (Reg. No. 6009306) in soil by LC-MS/MS~~
~~2015/1000961~~
~~**Guidelines:** OPPTS 850.7100, OPPTS 835.6100, PR Notice 2011-3,~~
~~SANCO/3029/99 rev. 4, 2000 (11 July 2000)~~
~~SANCO/825/00 rev. 8.1, 2010 (16 November 2010)~~
~~**GLP:** yes~~

~~The title has slightly changed from the application submitted as the analyte was allocated a different internal BASF Reg. No. This changed from 6002320, which was supposed to contain only the relevant cis II isomer, whereas the provided analyte 6009306 is a mixture of all four cypermethrin isomers, hence it was allocated a different unique identifier number. Apparently, during synthesis the cis II isomer (alpha-cypermethrin) could not be purified for technical reasons.~~

~~The method allows the determination of the metabolite M310I017 (Reg. No. 6009306, (cyano[3-(4-hydroxyphenoxy)phenyl]methyl (1RS,3RS) 3-(2,2-dichloroethenyl) 2,2-dimethylcyclopropanecarboxylate) in soil by LC-MS/MS.~~

~~The study is at the time of submission of the dossier still ongoing as synthesis and certification of required reference compound has been accomplished late in the process by the fourth quarter 2014. Expected finalisation date of the GLP study will be the first quarter of 2015. Upon finalisation of the study, the relevant documentation will be immediately submitted.~~

Report: CA 4.1.2/6
Geschke, S. (2015)
Validation of BASF analytical method L0286/01: Determination of Residues of Reg. No. 6009306 (M310I017cis, hydroxylated cypermethrin) in two different Soil Types
2015/1000961
Guidelines: OPPTS 850.7100, OPPTS 835.6100, PR Notice 2011-3, SANCO/3029/99 rev. 4, 2000 (11 July 2000), SANCO/825/00 rev. 8.1, 2010 (16 November 2010)
GLP: yes
(Landesamt fuer Umwelt, Messungen und Naturschutz Baden-Wuerttemberg, Karlsruhe, Germany)

Principle of the method L0286/01:
The analytical method was used for the determination of a cypermethrin metabolite. The analytical method was based on method R0034/01. The sample extraction was adapted to extract the hydroxylated cypermethrin. A 5.0 g soil sample aliquot was extracted with 0.1% formic acid in acetonitrile. One aliquot of the extract was then centrifuged for 5 min at 4000 rpm. An aliquot was taken and evaporated to dryness under a stream of nitrogen at 50°C and reconstituted in acetonitrile/pure water 1/1 v/v + 0.1% formic acid. The residue in the extract was determined using LC-MS/MS (Waters Acquity UPLC HSS T3, 150 × 2.1 mm, 1.8 µm, quantitation transition: 430 → 207, confirmation transition: 432 → 209). External calibration.

Conditions for gradient elution at a flow rat of 400 µL/min:

Time (min)	Mobile phase A : 4 mM ammonium formate solution in water + 0.1% formic acid	Mobile phase B: 4 mM ammonium formate solution in methanol + 0.1% formic acid
0.0	95	5
1.0	95	5
4.0	2	98
6.9	2	98
7.0	95	5
8.0	95	5

Specificity/Interferences: Method is highly selective and specific as 2 mass transitions were monitored (no further confirmatory method is required). The method was validated for both mass transitions.

No interferences have been observed at the retention time of the analyte from the soil control samples.
Representative chromatograms for matrix-matched calibration solutions, controls and fortified samples at LOQ and 10 × LOQ are provided for each concerned mass transition monitored. Product ion spectrum for the analyte was provided for the 430 and 432 m/z.

Linearity: Determination at 8 concentrations (single injection). Method is linear $r \geq 0.9999$ in the 0.1 - 20 ng/mL range (corresponding to a 0.0002 – 0.04 mg/kg range) for the two mass transitions.
The concentrations of the samples meet the calibration range.

Accuracy: Soil matrices were fortified with the analyte at two fortification levels (0.001 and 0.01 mg/kg). For each fortification levels, 5 replicates were analysed. 2 replicates of unfortified samples were also examined for each soil type. Mean recoveries can be consulted in Table **4.1.2-14**.

Repeatability: RSD remains below 20% at each fortification level for all analytes. RSD are presented in Table **4.1.2-14**.

LOQ: 0.001 mg/kg.

Table 4.1.2-14: Recoveries for hydroxylated cypermethrin in soils using LC-MS/MS method L0286/01

Matrix	Fortification Levels (ppm)	n	Recovery (%)	Average Recovery (%)	%RSD
Soil Lufa 2.2	Primary Quantitation (*m/z* 430.0 → *m/z* 207)				
	0.001	5	98, 96, 106, 102, 101	101	4
	0.01	5	94, 90, 95, 89, 94	72	3
	Confirmatory Quantitation (*m/z* 432.0 → *m/z* 209)				
	0.001	5	98, 95, 101, 97, 92	97	3
	0.01	5	95, 91, 96, 90,99	94	4
Soil Lufa 5M	Primary Quantitation (*m/z* 430.0 → *m/z* 207)				
	0.001	5	97, 95, 95, 91, 92	94	3
	0.01	5	99, 97, 100, 100, 94	98	3
	Confirmatory Quantitation (*m/z* 432.0 → *m/z* 209)				
	0.001	5	97, 101, 103, 95, 98	99	3
	0.01	5	98, 98, 101, 97, 95	98	2

Stability

The calibration solutions were stable for at least 10 days when stored refrigerated. The analyte is stable in the final extracts if stored in the refrigerator for 9 days.

Conclusion

Method L0286/01 (based on method R0034/01 - LC-MS/MS) is fully validated according to SANCO/3029/99 rev.4 and SANCO/825/00 rev. 8.1. The mean recovery at each fortification level is within the 70-110 % range for both mass transitions and the repeatability is always below 20%. The method has been shown to be linear (second order) and specific. No confirmatory method is required since two mass transitions have been monitored and validated.

The method is considered suitable to hydroxylated cypermethrin (metabolite of cypermethrin) in soil with a validated LOQ of 0.001mg/kg. The method can be used as a pre- as well as a post-registration method.

Water

Analytical methods for the determination of alpha-cypermethrin residues in water were evaluated in the context of the inclusion in Annex I of Directive 91/414/EEC. Methods evaluated previously are listed in Table 4.1.2-11 and summarized shortly below.

Table 4.1.2-15: Summary of peer-reviewed analytical methods for determination of alpha-cypermethrin residues in water

Method No.	Matrix	Method principle	Target analytes	LOQ µg/l	year	DocID	EU reviewed
SAMS 469-2	Water	GC/ECD; GC/MS for confirmation	Alpha-cypermethrin	0.01	1990	AL-243-001	Yes
SAMS 470-1	Water	GC/ECD; GC/ECD with alternative capillary column for confirmation	Permethrin	0.01	1988	AL-243-002	Yes
SAMS 468-1	Water	GC/ECD; GC/MS for confirmation	Cypermethrin	0.01	1988	AL-243-002	Yes
SAMS 469-1	Water	GC/ECD; GC/MS for confirmation	Alpha-cypermethrin	0.01	1988	AL-243-002	Yes
SAMS 469-2	Pond water	GC/ECD	Alpha-cypermethrin	0.01	1997	AL-243-003	Yes
SAMS 469-2	Surface water	GC/ECD; GC/MS for confirmation	Alpha-cypermethrin	0.05	1999	AL-243-006	Yes
M 3499	Water	sample prep. acc. to SAMS 469-2; GC/MS (confirmatory method)	Alpha-cypermethrin	0.05	2001	AL-210-012	Yes

For completeness of information, summaries of already EU-peer reviewed analytical methods are presented for completeness of information.

Report:	CA 4.1.2/7 Anonymous, 1990 Determination of residues of Alphacypermethrin in water - Gas chromatographic method
	AL-243-001
Guidelines:	none
GLP:	No

Report:	CA 4.1.2/8 Sherren A.J., 1990 Development of methods for the analysis of water for residues of Permethrin, Cypermethrin and Alphacypermethrin
	AL-243-002
Guidelines:	none
GLP:	No

Report:	CA 4.1.2/9 Pelz S. et al., 1997 Validation of method SAMS 469-2 for the determination of AC 900049 (Alphacypermethrin) applied as a formulation (FastacTM 100 G/L OESC insecticide) in pond water
	AL-243-003
Guidelines:	none
GLP:	Yes (Behoerde fuer Arbeit, Gesundheit und Soziales, Freie und Hansestadt Hamburg, Hamburg)

Report:	CA 4.1.2/10 Werle H., 1999 Alphacypermethrin (CL 900049) validation of method SAMS 469-2 for the determination of residues in surface water
	AL-243-006
Guidelines:	EEC 91/414,EEC 96/46,BBA Guideline Residue Analytical Methods for Post-Registration Control Purposes of July 21 1998,Guidance Document of Residue Analytical Methods 8064/VI/97 rev. 4 15.12.1998
GLP:	Yes (Umweltministerium Baden Wuerttemberg, Stuttgart)

Principle of the method:
Water samples are extracted by solvent partition with hexane and, if required, the extract is cleaned up using a Florisil disposable cartridge.
Alpha-cypermethrin is determined by GC with electron capture detection (ECD), using either *capillary column* (5% phenyl methyl silicone; 15m×0.32mm, 0.25 µm) or *packed column* (GE-XE 60 2% (m/m) on Gas Chrom Q (100-120 mesh)); quantification by external standardization. Analysis by capillary column is the preferred method. If required, residues may be confirmed by GC-MS (CPSil 5CB), MS operated in negative ion chemical ionisation mode (ions monitored: m/e 207 and 209).
The packed column does not allow the distinction between the different isomers of cypermethrin whereas the capillary column does. Under the conditions listed for GC-MS for confirmation purposes, the four isomers of cypermethrin are not resolved and elute as a single peak. Thus the confirmation indicates the presence of cypermethrin but does not distinguish the Cis-2 isomer.
It should be noted that for validation of SAMS 469-2 under the study by Werle 1999, modifications to the GC conditions occurred compared to the initial method (for GC-ECD: DB5 column, 30m×0.25mm, 0.25µm, differences in the injection and oven program and for GC-MSD incl. column Optima 5, 25m×0.25mm, 0.25µm and different carrier gas).
The method development of SAMS 469-2 in pond water was performed in support of aquatic toxicity studies with modified conditions (column FS capillary column 30m × 0.53 mm, 100% methyl silicone, splitless mode in place of FS capillary column 15 m × 0.32 mm, 5 % phenyl methyl silicone, split ratio 10:1) compared to the initial SAMS 469-2 method.

Specificity/Interferences*:*	Typical GC-ECD chromatograms, resp. obtained on packed column (SAMS 469-02) and capillary column (SAMS 469-01), are shown. Control samples exhibit no interfering peaks at the retention time of alpha-cypermethrin; control and blank data were stated to be < 0.01 µg/L.
	The method can be confirmed by GC-MS with method M3499, described below.
Linearity:	Method was found to be linear in the 0.0126 to 0.502 µg/mL (n=5, duplicate injection) with a correlation coefficient R^2 = 0.9926. The calibration curve and the regression equation were provided in the study report (determination with the capillary GC-ECD modified method only). Matrix effects were not demonstrated but can be sensibly reduced by the clean-up step applied.
	In SAMS 469-2 applied in pond water: method was found linear in the 0.00503 – 0.503 µg/mL range (n = 4 - duplicate injections for some concentrations) with a correlation coefficient r = 0.9997. The linear curve and the corresponding equation were provided.
Recovery/Precision:	see Table **4.1.2-16**
Limit of quantitation*:*	The limit of quantitation (LOQ) of the method for both metabolites, defined by the lowest fortification level is 0.05 mg/kg.

Table 4.1.2-16: Validation of methods SAMS 469-01 and SAMS 469-02

Matrix	Analyte	Fortification level (µg/L commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
source water (analysis by packed column) SAMS 469-02	alpha-cypermethrin	0.05 0.20 0.50	5 5 5	90 - 120 90 - 105 80 - 120	107 95 100	10.2 6.5 15.4
		0.05 - 0.50	15	80 - 120	100.7	11.7
source water (analysis by capillary column) SAMS 469-01	alpha-cypermethrin	0.10 0.20	2 2	85 - 90 95 - 95	87.5 95	(4.0) (0.0)
		0.10 - 0.20	4	85 - 95	91.3	5.3
surface water (analysis by capillary column) SAMS 469-02 (modified)	alpha-cypermethrin	0.05 0.5	5 5	80-103 78-107	88 89	8.9 12
		0.05-0.5	10	78-107	89	9.7

Storage stability: Water samples must be stored cold (at 4 °C) and extracted within 3 days of sampling.

Conclusion: **The packed column method is suitable for alpha-cypermethrin residue analysis in source water with a LOQ of 0.05 µg/L. The capillary column method is suitable for alpha-cypermethrin residue analysis in source and surface water with a LOQ of 0.05 µg/L.**

Report:	CA 4.1.2/4 Xu B., 2001 BAS 310 I (Alpha-Cypermethrin): Validation of method M 3499 for the confirmation of BAS 310 I residues in water soil and blood by GC/MS AL-210-012
Guidelines:	Guidance Document on Residue Analytical Methods (SANCO/825/00rev.6)
GLP:	Yes (United States Environmental Protection Agency)

Principle of the method:
Method M 3499 is used to confirm the specificity of method SAMS 469-2 (GC-ECD). The procedure for sample preparations is the same as the one outlined in SAMS 469-2 but an alternative detection method is used (determination by capillary GC (DB-5MS, 5m × 0.25 mm i.d., 0.25 µm) with MSD in SIM mode (m/z 207, 209 and 211). Ground water was used as matrix.

Specificity/Interferences:	Specificity of method SAMS 469-2 is demonstrated by using GC-MS as an alternative method of detection. Untreated control samples exhibit no significant interferences at retention time of alphacypermethrin (control values < 30% of LOQ)
Linearity:	The response of the GC-MS system (= peak area) to alphacypermethrin was demonstrated to be linear over a concentration range from 0.0025 to 0.04 µg/mL (n = 5); r > 0.999 for each ion (207, 209 and 211). Samples are diluted if necessary to meet the calibration range.

Recovery/Precision: See Table **4.1.2-17**.

Limit of quantitation:	The limit of quantitation (LOQ) of the method, defined by the lowest fortification level is 0.05 µg/L.

Table 4.1.2-17: Validation of confirmatory method M 3499 for groundwater

Analyte	Fortification level (µg/L commodity)	Number of samples	% Retention Time Difference (RTD) (ion m/z 207)	% Ion Ratio Difference (IRD)	
				207/209	207/211
alphacypermethrin	0.05	3	0.1 0.0 0.1	- 0.1 - 0.8 - 0.2	- 4.7 - 3.0 - 5.0

% RTD = (sample retention time – average standard retention time) x 100/average standard retention time
% IRD = (sample ion ratio – standard average ion ratio) x 100/standard average ion ratio

Conclusion:	**Method M 3499 (GC-MS) is suitable as qualitative confirmatory method to SAMS 469-2 (GC-ECD) for determination of alphacypermethrin residues in water (LOQ 0.05 µg/L).**

No new methods for water were required for risk assessment in support of environmental fate studies. A newly developed analytical method for post-approval and monitoring purposes is described in detail under CA 4.2/7, respective independent laboratory validation under CA 4.2/8.

Air

Analytical methods for the determination of alpha-cypermethrin residues in air were evaluated in the context of the inclusion in Annex I of Directive 91/414/EEC. Methods evaluated previously are listed in Table **4.1.2-18** and summarized shortly below.

Table 4.1.2-18: Summary of peer-reviewed analytical methods for determination of alpha-cypermethrin residues in air

Method No.	Matrix	Method principle	Target analytes	LOQ µg/m³	year	DocID	EU reviewed
AMS 887-01	Air	HPLC-UV	Alpha-cypermethrin	3 µg/m³ for 15L air, 0.1 µg/m³ for 480L air	Not reported	AL-210-002	Yes
SAMS 534-1	Air	GC/NPD, GC/ECD, GC/MS	Alpha-cypermethrin	0.02	1992	AL-241-001	Yes
RCC project no. 249120	Air	GC/NPD	Alpha-cypermethrin	0.01	1992	AL-241-002	Yes

For completeness of information, summaries of already EU-peer reviewed analytical methods are presented for completeness of information.

Report: CA 4.1.2/11
Anonymous, 1992
Determination of crystalline Fastac in aerosols
AL-210-002
Guidelines: none
GLP: No

Principle of the method:
A known volume of air (15 L or 480 L, dependent on the expected concentration) is drawn through a silver membrane filter with glassfibre prefilter and cellulose pad (at 1 L/min) to trap the crystalline alpha-cypermethrin present, after which the inlet and outlet of the filter holder are sealed. The filters are extracted by sonication with diethylether and the resulting solution is reduced by evaporation. The enriched solution is analyzed by HPLC (Spheri 5 RP 18; isocratic elution) with UV detection at 215 nm.

As the method has already been evaluated as not appropriately validated before, not further data are summarised for this method.

Report:	CA 4.1.2/12 Anonymous, 1992 Determination of Alphacypermethrin in air using an adsorbent trap - Gas chromatographic method AL-241-001
Guidelines:	none
GLP:	No

Principle of the method:
Air to be sampled (120 L) is pumped through a tube packed with Chromosorb 102 at 250 mL/min, after which the tube is capped and stored at 4 °C pending analysis. The alpha-cypermethrin is desorbed from the Chromosorb 102 (front and back section separately) by sonication with acetone, dodecane is added and the acetone is evaporated.
The resulting solution is analyzed by capillary GC (DB-5; 0.25 µm) with nitrogen phosphorous selective detection (NPD); quantification by external standardization. An electron capture detector could also be used, provided the final extracts are sufficiently clean; clean-up of the extract may be achieved by using a Florisil cartridge. If required, residues may be confirmed by GC-MS (CPSil 5CB), MS operated in negative ion chemical ionisation mode (ions monitored : m/e 207 and 209).

Specificity/Interferences: Typical GC-NPD chromatograms are shown. Control sample appears to exhibit some interference at retention time of alpha-cypermethrin, but control and blank data were nevertheless stated to be < 0.02 µg/m³.

Recovery/Precision: see Table **4.1.2-19**

Limit of quantitation: The limit of quantitation (LOQ) of the method, defined by the lowest fortification level is 0.02 µg/m³.

Table 4.1.2-19: Validation of method SAMS 534-01

Matrix		Analyte	Fortification level (µg/m³ commodity)	Recovery			
				Number of samples	Range (%)	Mean (%)	RSD (%)
air (T : 21-30 °C; RH : 40-90%)		alpha-cypermethrin	0.02 0.10 0.20 0.50	5 5 4 5	98 - 115 86 - 105 91 - 94 75 - 94	104.6 92.6 92.5 83	7.8 8.1 1.4 10.3
			0.02 - 0.50	19	75 - 115	93.2	11.2

Conclusion: **The method is suitable for alpha-cypermethrin residue analysis in air with a LOQ of 0.02 µg/m³.**

Report:	CA 4.1.2/13 Mueller-Kallert H., 1992 Development of a method for the determination of Alphacypermethrin in air AL-241-002
Guidelines:	BBA I 1-2
GLP:	Yes (Eidgenoessisches Department des Inneren, Bern, Schweiz)

This study referenced as Method AL-241-002 (1992/7001981) is similar to the peer-reviewed method AL-241-001 / 1992/7001991 (SAMS 534-01 – see above) and is based on SAMS 534-01. Method AL-241-001 has been validated again as a repeat of the method AL-241-002 for a regional submission.

Validation data found in the report are summarized here below:

Specificity/Interferences:	Typical GC-NPD chromatograms are shown. Considerable background was visible with NPD detection. However, this background noise was lower than signals resulting from a concentration equal to the LOQ.
Linearity:	Investigated range 0.01 – 05 µg/mL with a correlation coefficient of 0.9984. Equation and calibration curve were provided.
Recovery/Precision:	see Table **4.1.2-19**
Limit of quantitation:	The limit of quantitation (LOQ) of the method, defined by the lowest fortification level is 0.02 µg/m³.
Conclusion:	**The method is suitable for alpha-cypermethrin residue analysis in air with a LOQ of 0.02 µg/m³.**

No new methods for air are required for risk assessment in support of environmental fate studies. A newly developed analytical method for post-approval and monitoring purposes is described in detail under CA 4.2/9.

(b)Methods in soil, water and any additional matrices used in support of efficacy studies

No stand-alone validation of analytical methods was required in support of efficacy studies.

(c)Methods in feed, body fluids and tissues, air and any additional matrices used in support of toxicological studies

No stand-alone methods for toxicological studies were required. However, a newly developed method for the determination of alpha-cypermethrin in blood and urine was developed and validated for post-approval and monitoring purposes and is described in detail in CA 4.2/10.
A summary table of methods already evaluated is also presented in CA 4.2/10 for the reviewer's convenience.

Detailed summaries of the analytical methods used for data-generation purposes in support of toxicological gavage and feeding studies are given below. Analytical methods used for data generation of stability assessment are also summarised below. The analytical methods were not allocated a unique document identifier, but the summaries below are given under the unique document identifier (DocID) of the respective toxicological study.

Report:	CA 4.1.2/14 Maas X., Bending P., 2015 a Alpha-Cypermethrin: Analysis of alpha-Cypermethrin in rodent samples originating from a mammalian toxicity study 2015/1175543
Guidelines:	none
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Principle of the method

The analytical procedure/method was developed and validated based on QueChERS extraction with subsequent clean-up and LC-MS/MS and adapted for the determination of alpha-cypermethrin (Cis II isomer).
A homogenized sample (rodent body or rodent brain) was weighed into a 50 mL centrifuge tube and water was added. After shaking manually for 30 sec, acetonitrile was added and the sample was shaken manually for 1 min. Then, the content of a Dispersive SPE (dSPE) citrate extraction tube was added and shaken manually for 1 min. After centrifugation for 5 min at 3000 rpm, 6 mL of the acetonitrile layer was transferred to a Dispersive SPE PSA SPE clean-up tube. The sample was shaken manually for 30 sec and then centrifuged for 5 min at 3000 rpm. An aliquot of 1 mL of the supernatant was transferred to an autosampler vial and 10 µL of acetonitrile/formic acid (50/1, v/v) was added.
Analysis was accomplished by LC-MS/MS. The chromatography was performed on a Waters Acquity UPLC HSS T3 column with a flow rate of 0.4 mL/min and a gradient mixture of water/formic acid/10 mM ammonium formate (1000/1/0.63, v/v/w) and methanol/formic acid/10 mM ammonium formate (1000/1/0.63, v/v/w). Detection was accomplished by electrospray ionization (positive mode) at mass transitions 433→191 for quantification and 435→193 for confirmation.

Recovery findings

The described method is suitable to determine residues of alpha-cypermethrin in samples of rodent body and rodent brain. Samples were spiked with alpha-cypermethrin with 0.01 mg/kg (LOQ) and 0.1 mg/kg (10xLOQ) and rodent body samples additionally with 0.2 mg/kg (20xLOQ). All average recovery values were between 70% and 120%. The detailed results are given inTable 4.1.2-20.

Table 4.1.2-20: Recovery results of alpha-cypermethrin (Cis II isomer) in rodent brain and body samples

Matrix	m/z	Fortification level [mg/kg]	Number of Replicates	Mean Recovery [%]	RSD [%]	Overall Recovery [%]	RSD [%]
Rodent Brain	433 → 191	0.01	3	103	1	105	3
		0.1	3	107	4		
	435 → 193	0.01	3	104	2	105	3
		0.1	3	106	4		
Rodent Body	433 → 191	0.01	3	96	2	95	7
		0.1	3	98	6		
		0.2	1	83	--		
	435 → 193	0.01	3	102	3	98	8
		0.1	3	99	6		
		0.2	1	84	--		

RSD = Relative standard deviation

Linearity

The linearity was tested at concentrations between 0.01 ng/mL and 25 ng/mL for rodent brain and 0.25 ng/mL to 30 ng/mL for rodent body, prepared in acetonitrile/formic acid (1000/1, v/v). Linear correlation with coefficients of $r > 0.99$ were obtained. Seven (rodent brain) and eight (rodent body) calibration standards distributed over the range given above were used, respectively.

Specificity

LC-MS/MS is a highly specific self-confirmatory technique. Under the described conditions, the method is specific for the determination of alpha-cypermethrin in rodent brain and rodent body samples. Analysis is possible at two mass transitions.

Due to the high selectivity and specificity of LC-MS/MS an additional confirmatory technique was not necessary.

Interference

No residues of alpha-cypermethrin were present above 0.002 mg/kg (20% of LOQ) in any of the blank control specimens.

Matrix Effects

Matrix effects were tested by comparing the response of the analyte in calibration solutions in solvent versus response in matrix-matched calibration standards. No significant effects (< 20%) were observed.

Limit of Quantification

The limit of quantification (LOQ) is defined by the lowest fortification level of 0.01 mg/kg for alpha-cypermethrin.

Limit of Detection

The limit of detection (LOD) of alpha-cypermethrin is defined by the lowest calibration level with 0.0002 mg/kg for rodent brain and 0.001 mg/kg for rodent body.

Repeatability The relative standard deviation (RSD, %) for all fortification levels were < 20% for alpha-cypermethrin.

Reproducibility Reproducibility of the method was not determined within the validation study.

Conclusion **The described method for analysis of alpha-cypermethrin (Cis II isomer) in rodent brain and rodent body samples used LC-MS/MS for final determination, which is a highly specific technique.**

It could be demonstrated that the method fulfils the requirements with regard to linearity, specificity, repeatability, limit of quantification, and recoveries and is therefore applicable to correctly determine residues of alpha-cypermethrin (Cis II isomer) in rodent brain and body samples.

Report:	CA 4.1.2/15 Becker M., Kamp H., 2015 a Analytical report - BAS 310 I (Alpha-Cypermethrin) - Stability analysis in corn oil 2014/1170685
Guidelines:	none
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Executive Summary

In the context of toxicological studies, the stability of alpha-cypermethrin (BAS 310 I) in the vehicle corn oil was investigated in one stability study.

Standard solutions were stored at room temperature and analyzed at day 0 and after 4 h, 4 d, and 7 days.

Stability of alpha-cypermethrin at a nominal concentration of 200 mg/L was given over a time period of 7 days of storage at ambient temperature.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Internal code:	BAS 310 I
Common name:	alpha-cypermethrin
Batch No.:	PMAM000622
Test substance No.	01/0265-5
Purity:	99.2%

B. STUDY DESIGN

1. Experimental Conditions

50.0 mg of alpha-cypermethrin were dissolved in 20 mL acetone. An aliquot of 80 µL was taken and evaporated at room temperature. Then, 1 mL of corn oil was added. For each sampling time point a separate sample was prepared. The final nominal concentration was 200 mg/L.

2. Description of analytical procedures

Analysis was accomplished by gas chromatography (GC) equipped with FID (detector temperature 340°C). The chromatography was performed on a DB-1 MS column at a constant flow of 1.4 mL/min using helium as carrier gas. A temperature gradient was run, starting with a temperature of 230°C (hold time 23 min), followed by a temperature increase of 25°C/min to 340°C (hold time 30 min). Run time was approximately 58 min.

Principle of the method:
Samples were diluted completely with acetone using appropriate volumetric flasks to obtain sample solutions with alpha-cypermethrin concentrations that match the actual calibration range of 19.2 mg/L to 192 mg/L. Adequate dilutions with matrix solutions were performed as necessary. It was ensured, that the test substance was completely dissolved in the solutions.

Validation:

Specificity/Interferences:	The study report provided chromatograms for blank matrix, matrix-matched calibration standard and the stability sample after 7 days. No interferences seem to occur at the retention time of the analyte. Chromatograms were also provided for control, calibration and samples in study (DocID 2014/1275120) and did not show any interferences above 30% of the lowest calibration level.
Linearity:	The linearity of the method was investigated at concentrations between 19.2 to 192 mg/L in corn oil matrix (matrix-matched calibration solutions). Linear correlation coefficient and regression equation were not provided but the calibration curve showed the good linearity of the method in the investigated range (six calibration concentrations were used to demonstrate the linearity). The method mentioned that samples are diluted if required to meet the calibration range.
Recovery/Precision:	Not demonstrated as such. The stability of alpha-cypermethrin in corn oil was determined in one stability study over a time period of 7 days at room temperature at a nominal concentration of 200 mg/L. Over the investigated time period of 7 days, all measured concentrations were in the range between 90% to 110% of the nominal concentration. The detailed results are summarized in Table 4.1.2-21.
Limit of quantification:	An LOQ of 200 mg/L is proposed.
Conclusion:	**The method described is suitable for the quantification of alpha-cypermethrin in corn oil with a limit of quantification of 200 mg/L.**

II. RESULTS AND DISCUSSION

The stability of alpha-cypermethrin in corn oil was determined in one stability study over a time period of 7 days at room temperature at a nominal concentration of 200 mg/L.

Over the investigated time period of 7 days, all measured concentrations were in the range between 90% to 110% of the nominal concentration. The detailed results are summarized in Table 4.1.2-21.

Table 4.1.2-21: Results for stability analysis of alpha-cypermethrin in corn oil

Matrix	Time after starting	Target concentration [mg/L]	Concentration found [mg/L]	Nominal concentration [%]
Corn oil	0 h	200	196.87	98.4
	4 h	200	198.43	99.2
	4 d	200	196.65	98.3
	7 d	200	195.54	97.8

4.1.2-22: Results for concentration control of alpha-cypermethrin in corn oil (2014/1275120)

Matrix	Target concentration [mg/L]	N	% Mean recovery (range)	RSD
Corn oil	200	3	97.3 (96.2, 99.7, 99.0)	1.5
	350	3	100.2 (10.7, 99.0, 100.8)	1.0
	660	3	99.6 (100.1, 99.1 99.7)	0.5

III. CONCLUSION

Based on the analytical results it was demonstrated that alpha-cypermethrin was stable in corn oil over a time period of 7 days stored at room temperature at a nominal concentrations of 200 mg/L.

Report:	CA 4.1.2/16 Grauert E.,Kamp H., 2014 a BAS 310 I (Alpha-Cypermethrin) - Stability analysis in 1% Carboxymethylcellulose in drinking water 2014/1275135

Report:	CA 4.1.2/17 Grauert E.,Kamp H., 2015 a BAS 310 I (Alphacypermethrin) - Stability analysis in 1% Carboxymethylcellulose in drinking water 2015/1093547
Guidelines:	none
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

The data from M-CA 4.1.2/17 and M-CA 4.1.2/18 are summarised together and given below. An overview of the analytical procedures given below is done under the unique document identifier of the original toxicological studies.

Executive Summary

In the context of toxicological studies, the stability of alpha-cypermethrin (BAS 310 I) in the vehicle 1% carboxymethylcellulose (CMC) in drinking water was investigated in two stability studies.
In each stability study, standard solutions were stored at room temperature and analyzed at day 0 and after 4 h, 24 h, 96 h and 7 days.

Stability of alpha-cypermethrin at nominal concentrations of 201.6 mg/L and 104.4 mg/L was given over a time period of 7 days of storage at ambient temperature.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Internal code:	BAS 310 I
Common name:	alpha-cypermethrin
Batch No.:	PMAM000622
Test substance No.	01/0265-5
Purity:	99.2%

B. STUDY DESIGN

1. Experimental Conditions

BASF DocID 2014/1275135
50.4 mg of alpha-cypermethrin were dissolved in 10 mL acetone. An aliquot of 40 µL was taken and evaporated at room temperature. Then, 1 mL of 1% carboxymethylcellulose (CMC) in drinking water was added. For each sampling time point a sample was prepared. The final nominal concentration was 201.6 mg/L.

BASF DocID 2015/1093547
52.2 mg of alpha-cypermethrin were dissolved in 25 mL acetone. An aliquot of 50 µL was taken and evaporated at room temperature. Then, 1 mL of 1% carboxymethylcellulose (CMC) in drinking water was added. For each sampling time point a sample was prepared. The final nominal concentration was 104.4 mg/L.

2. Description of analytical procedures

BASF DocID 2014/1275135
Analysis was accomplished by gas chromatography (GC) equipped with FID (detector temperature 340°C). The chromatography was performed on a DB-1 MS column at a constant flow of 1.4 mL/min using helium as carrier gas. A temperature program was run, starting with a temperature of 230°C (hold time 23 min), followed by a temperature increase of 25°C/min to 340°C (hold time 5 min). Run time was approximately 32 min.

Principle of the method:
Samples were diluted completely with solvent solutions (900 mL acetone + 100 mL citric acid 5% in water, v/v) using appropriate volumetric flasks to obtain sample solutions with alpha-cypermethrin concentrations that match the actual calibration range of 9.48 mg/L to 94.8 mg/L. Adequate dilutions with matrix solutions were performed as necessary. It was ensured, that the test substance was completely dissolved in the solutions.

BASF DocID 2015/1093547
Analysis was accomplished by gas chromatography (GC) equipped with FID (detector temperature 340°C). The chromatography was performed on a DB-1 MS column at a constant flow of 1.4 mL/min using helium as carrier gas. A temperature program was run, starting with an initial temperature of 70°C (hold time 3 min), followed by a temperature increase of 25°C/min to 230°C (hold time 22 min) and further increase by 30°C/min to 340°C (hold time 5 min). Run time was approximately 40 min.

Principle of the method:
Samples were transferred into volumetric flasks with approximately 5 to 10 mL of a mixture of acetone/citric acid 5% in water (1+1, v/v) and filled up to the mark with solvent solution (950 mL acetone + 50 mL citric acid 5% in water, w/v) to obtain sample solutions with alpha-cypermethrin concentrations that match the actual calibration range of 1.002 mg/L to 10.02 mg/L. Adequate dilutions with matrix solutions were performed as necessary. It was ensured, that the test substance was completely dissolved in the solutions.

Validation:

Specificity/Interferences: The study report provides chromatograms for blank matrix, matrix-matched calibration standard and the stability sample after 4 hours for the first study and after 7 days for the second study. No interferences occur at the retention time of the analyte.

Linearity: The linearity of the method was investigated at concentrations between 9.48 to 94.8 mg/L and 1.002 to 10.02 mg/L in 1% CMC in drinking water (matrix-matched calibration solutions), respectively. Linear correlation coefficient and regression equation are not provided but the calibration curve shows the good linearity of the method in the investigated range (six and five calibration concentrations were used to demonstrate the linearity, respectively).

Recovery/Precision: Not demonstrated by fortification at different levels by means of several replicates. Only stability data are available. In the investigated time period of 7 days, all measured concentrations in both stability studies were in the range between 90% to 110% of the nominal concentrations. The detailed results for both studies are summarized in Table 4.1.2-23.

Limit of quantitation: Not stated.

II. RESULTS AND DISCUSSION

The stability of alpha-cypermethrin in 1% carboxymethylcellulose (CMC) in drinking water was determined in two stability studies [*BASF DocID 2014/1275135 and BASF DocID 2015/1093547*] over a time period of 7 days at room temperature at nominal concentrations of 201.6 mg/L and 104.4 mg/L.

Over the investigated time period of 7 days, all measured concentrations in both stability studies were in the range between 90% to 110% of the nominal concentrations. The detailed results for both studies are summarized in Table 4.1.2-23.

Table 4.1.2-23: Results for stability analysis of alpha-cypermethrin in 1% carboxymethylcellulose in drinking water

Matrix	BASF DocID	Time after starting	Target concentration [mg/L]	Concentration found [mg/L]	Nominal concentration [%]
1% CMC in drinking water	2014/1275135	0 h	201.6	203.10	100.7
		4 h	201.6	191.85	95.2
		24 h	201.6	202.50	100.4
		96 h	201.6	205.33	101.9

	2015/1093547	0 h	104.4	107.52	103.0
		4 h	104.4	101.73	97.4
		24 h	104.4	103.08	98.7
		96 h	104.4	102.09	97.8
		7 d	104.4	96.88	92.8

CMC = carboxymethylcellulose

III. CONCLUSION

Based on the analytical results it was demonstrated that alpha-cypermethrin was stable in 1% carboxymethylcellulose in drinking water over a period of 7 days stored at room temperature at nominal concentrations of 201.6 mg/L and 104.4 mg/L.

Report:	CA 4.1.2/18 Becker M.,Kamp H., 2015 b Analytical report - 3-Phenoxybenzoic acid (metabolite of BAS 310 I, Alpha-Cypermethrin) - Concentration control analysis in Polyethylene glycol 400 2015/1003984
Guidelines:	none
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Principle of the method

Samples were diluted completely with acetonitrile using appropriate volumetric flasks to obtain sample solutions with 3-phenoxybenzoic acid (metabolite of alpha-cypermethrin) concentrations that match the actual calibration range of 5.21 mg/L to 52.1 mg/L. Adequate dilutions with matrix solutions were performed as necessary. It was ensured, that the test substance was completely dissolved in the solutions.
Analysis was accomplished by HPLC with UV-detection (DAD) at 230 nm with reference wavelength of 360 nm. The chromatography was performed on a Kinetex C18 column with a flow rate of 3.0 mL/min and a gradient mixture of acetonitrile/water/formic acid (950/50/1, v/v/v) and water/acetonitrile/formic acid (950/50/1, v/v/v).

Recovery findings

The described method is suitable to determine residues of 3-phenoxybenzoic acid in polyethylene glycol 400. Samples were spiked with 3-phenoxybenzoic acid with concentrations of 50 mg/g, 100 mg/g and 200 mg/g. The calculated mean values of both sample sets (main and retain samples) were in the range between 85% and 88%. Values that are in the range of ± 15% of the nominal concentrations can be regarded as acceptable for liquid test substance preparations. The detailed results are given in Table 4.1.2-24.

Table 4.1.2-24: Results of concentration control of 3-phenoxybenzoic acid in polyethylene glycol 400

Matrix	Sample set	Amount [mg/g]	Nominal concentration [mg/g]	Nominal concentration [%]	Average nominal concentration [a] [%]	RSD [a] [%]
Polyethylene glycol 400	Sample set a (main samples)	42.071	50	84.1	84.7	0.7
		85.172	100	85.2		
		169.433	200	84.7		
	Sample set b (retain samples)	44.061	50	88.1	87.5	0.6
		87.352	100	87.4		
		174.111	200	87.1		

RSD = Relative standard deviation
[a] Average nominal concentrations and RSD values are based on calculations of the data originating from the study report.

Linearity The linearity was tested at concentrations between 5.21 mg/L and 52.1 mg/L, prepared in matrix solution (preparation procedure according to the description in principle of the methods). Linear correlation with coefficients of $r > 0.995$ were obtained. Five calibration standards distributed over the range given above were used.

Specificity The identification and quantification of 3-phenoxybenzoic acid were based on the selected wavelength at 230 nm and the retention time. Under the described conditions, the method is specific for the determination of 3-phenoxybenzoic acid in polyethylene glycol 400. As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Interference No test substance was detected in the polyethylene glycol 400 control samples with a concentration of $\geq 30\%$ of the lowest calibration solution.

Matrix Effects Matrix-matched calibration solutions were used for quantification of 3-phenoxybenzoic acid, hence any potentially occurring matrix effect has already been accounted for by adjusting the matrix in the standard solutions used for calibration.

Limit of Quantification The limit of quantification (LOQ) is defined by the lowest fortification level of 50 mg/g for 3-phenoxybenzoic acid.

Limit of Detection The limit of detection (LOD) of 3-phenoxybenzoic acid is defined by the lowest calibration level with 5.21 mg/L.

Repeatability	The relative standard deviation (RSD, %) for concentration levels were < 20% for 3-phenoxybenzoic acid.
Reproducibility	The average nominal concentrations in Table 4.1.2-24 are mean values of samples measured at different days (sample set a and b). The data are comparable, so a reproducibility is given.
Conclusion	**The described method is suitable for the determination of 3-phenoxybenzoic acid (metabolite of alpha-cypermethrin) in polyethylene glycol 400.**

Report:	CA 4.1.2/19 Becker M.,Kamp H., 2015 c Analytical report - 3-Phenoxybenzoic acid (metabolite of BAS 310 I, Alpha-Cypermethrin) - Plasma analysis for external studies 2015/1032402
Guidelines:	none
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.
The method was used to verify the mere presence of the test substance 3-phenoxybenzoic acid (metabolite of alpha-cypermethrin) in mouse plasma by using confirmation analysis.

Principle of the method

30 µL of plasma were mixed with 270 µL acetonitrile in a plastic micro centrifuge tube. After vortex mixing and protein precipitation, the samples were centrifuged at 13000 rpm for 5 min. The supernatant was directly analyzed by HPLC-MS. The chromatography was performed on an Ascentis Express C18 column with a flow rate of 0.25 mL/min and a gradient mixture of acetonitrile/water/formic acid (950/50/0.1, v/v/v) and water/acetonitrile/formic acid (950/50/0.1, v/v/v). Detection was accomplished by electrospray ionization (negative mode) at mass transitions 214.1→169.9 as quantifier and 214.1→93.3 as qualifier.

Recovery findings

The described method is suitable to verify residues of 3-phenoxybenzoic acid in mouse plasma by confirmation analysis. Samples spiked with 3-phenoxybenzoic acid with 2000 mg/kg body weight were analyzed 1 h and 4 h after application. The calculated mean values after 1 h and 4 h after application were in the range between 67.2% and 68.9%. Based on the analytical results it was concluded that 3-phenoxybenzoic acid was detected and confirmed in all mouse plasma samples, as the ion ratios of the quantifier and qualifier ion were comparable between the test substance 3-phenoxybenzoic acid at a dose level of 2000 mg/kg body weight and the calibration solution (± 20%). The detailed results are given in Table 4.1.2-25.

Table 4.1.2-25: Results of 3-phenoxybenzoic acid in mouse plasma at 1 hour and 4 hours after application

Matrix	Hours after application	Dose [mg/kg body weight]	Retention time (reference) 4.70 – 5.20	Ion ratio (reference) 53.13% - 79.68%	Average ion ratio [a] (reference) 53.13% - 79.68%	RSD [a] [%]	Results
Mouse plasma	1 h	2000	4.95	69.1	68.9	1.9	Complies
			4.95	70.1			
			4.95	67.5			
	4 h	2000	4.95	67.9	67.2	0.9	Complies
			4.95	66.7			
			4.95	67.0			

RSD = Relative standard deviation
[a] Average ion ratio and RSD values are based on calculations of the data originating from the study report.

Linearity Not applicable and in case of mere positive confirmatory analysis (positive test) not relevant.

Specificity The identification and quantification of 3-phenoxybenzoic acid were based on the analysis by HPLC-MS and by its retention time. Under the described conditions, the method is specific for the confirmation analysis of 3-phenoxybenzoic acid in mouse plasma. As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Interference No test substance was detected in the mouse plasma control samples with a concentration of ≥ 20% of the calibration solution with 27.1 ng/mL.

Matrix Effects Matrix-matched calibration solutions were used for quantification of 3-phenoxybenzoic acid, hence any potential matrix effects were accounted for by adjusting the matrix in the standard solutions used for calibration.

Limit of Quantification Not applicable and in case of mere positive confirmatory analysis (positive test) not relevant.

Limit of Detection Not applicable and in case of mere positive confirmatory analysis (positive test) not relevant.

Repeatability The relative standard deviation (RSD, %) for the tested concentration level was < 20% for 3-phenoxybenzoic acid.

Reproducibility The average ion ratios in Table 4.1.2-25 are mean values of samples measured at different time points. The data are comparable, so a reproducibility is given.

Conclusion	**The described method is suitable for the confirmation analysis of 3-phenoxybenzoic acid (metabolite of alpha-cypermethrin) in mouse plasma.**

Report:	CA 4.1.2/20 Becker M.,Kamp H., 2015 d 3-Phenoxybenzoic acid (metabolite of BAS 310 I, Alpha-Cypermethrin) - Stability analysis in DMSO (4h) 2015/1029517
Guidelines:	none
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Executive Summary

In the context of toxicological studies, the stability of 3-phenoxybenzoic acid (metabolite of alpha-cypermethrin - BAS 310 I) in the vehicle DMSO was investigated in one stability study.

Standard solutions were stored at room temperature and analyzed at day 0 and after 4 h.

Stability of 3-phenoxybenzoic acid at a nominal concentration of 103.2 mg/L was given over a time period of 4 hours of storage at ambient temperature.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Common name:	3-phenoxybenzoic acid
Batch No.:	AC12251-34
Test substance No.	01/0418-1
Purity:	100%

B. STUDY DESIGN

1. Experimental Conditions

51.6 mg of 3-phenoxybenzoic acid were dissolved in 20 mL DMSO. This solution was further diluted 1:25 with DMSO. The final nominal concentration was 103.2 mg/L.

2. Description of analytical procedures

Analysis was accomplished by HPLC with UV-detection (DAD) at 230 nm. The chromatography was performed on a Kinetex C18 column with a flow rate of 3.0 mL/min and an isocratic mixture (50/50) of acetonitrile/formic acid (1000/1, v/v) and water/formic acid (1000/1, v/v).

Principle of the method:
Samples were diluted completely with acetonitrile using appropriate volumetric flasks to obtain sample solutions with 3-phenoxybenzoic acid concentrations that match the calibration range of 2.04 mg/L to 20.4 mg/L. Adequate dilutions with matrix solutions were performed as necessary. It was ensured, that the test substance was completely dissolved in the solutions.

Validation:

Specificity/Interferences:	The study report provided chromatograms for blank matrix, matrix-matched calibration standard and the stability sample after 4 hours. No interferences seem to occur at the retention time of the analyte.
	The identification and quantitation of 3-phenoxybenzoic acid were based on the selected wavelength at 230 nm and the retention time. Under the described conditions, the method is specific for the determination of 3-phenoxybenzoic acid in DMSO as the method is only used for dose verification of known substances and known nominal concentrations. Hence, no additional confirmatory technique is necessary.
Linearity:	The linearity of the method was investigated at concentrations between 2.04 to 20.4 mg/L (matrix-matched calibration solutions), respectively. Linear correlation coefficient and regression equation were not provided but the calibration curve showed the good linearity of the method in the investigated range (five calibration concentrations were used to demonstrate the linearity).
Recovery/Precision:	Not demonstrated by means of fortification at different levels using different replicates. Only stability data are available. Over the investigated time period of 4 hours, all measured concentrations were in the range between 90% to 110% of the nominal concentrations. The detailed results for both studies are summarized in Table 4.1.2-26.

Limit of quantitation: Not stated but the lowest fortified level of 103.2 mg/L is proposed as limit of quantification.

Conclusion: **The method is suitable for the quantification of alpha-cypermethrin in DMSO; this was confirmed by the stability assessment.**

II. RESULTS AND DISCUSSION

The stability of 3-phenoxybenzoic acid in DMSO was determined in one stability study stored over a time period of 4 hours at room temperature at a nominal concentration of 103.2 mg/L.

Over the investigated time period of 4 hours, all measured concentrations were in the range between 90% to 110% of the nominal concentration. The detailed results are summarized in Table 4.1.2-26.

Table 4.1.2-26: Results for stability analysis of 3-phenoxybenzoic acid in DMSO

Matrix	Time after starting	Target concentration [mg/L]	Concentration found [mg/L]	Nominal concentration [%]
DMSO	0 h	103.2	108.9	105.5
	4 h	103.2	105.1	101.8

III. CONCLUSION

Based on the analytical results it was demonstrated that 3-phenoxybenzoic acid (metabolite of alpha-cypermethrin) was stable in DMSO over a time period of 4 hours stored at room temperature at a nominal concentration of 103.2 mg/L.

Report:	CA 4.1.2/21 [redacted] 1995 a WL85871: 52 week oral (dietary) toxicity study in dogs AL-427-001
Guidelines:	EPA 83-1
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Report:	CA 4.1.2/22
	[redacted] (1993) Validation of analytical method no. 5458 for the analysis of WL85871 in dog dietary formulations
	AL-245-005
Guidelines:	none stated
GLP:	not stated

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Principle of the method

10 g of the dog diet (SDS Type A) were weighed into a screw cap jar and the internal standard butylated hydroxytoluene was added. WL85871 (active substance alpha-cypermethrin) was extracted with acetone from dog diet by shaking the mixture for 1 hour at ambient temperature on a mechanical shaker. After filtration (0.45 µm) an aliquot of the supernatant was analyzed.
Analysis was accomplished by HPLC with spectrophotometric detection at 220 nm. The chromatography was performed on a TSK GEL ODS 80 Tm column with a flow rate of 2.0 mL/min and a mixture of methanol/water (80/20, v/v).

Recovery findings

The described method is suitable to determine residues of WL85871 in dog diet. Samples were spiked with WL85871 at concentration levels of 60 ppm, 120 ppm and 240 ppm and analyzed at the respective dose week. The calculated average values of all samples were in the range between 96.2% and 99.4%. The detailed results are given in Table 4.1.2-27.

Table 4.1.2-27: Results of the analysis of the test formulation WL85871 in dog diet

Matrix	Theoretical concentration [ppm]	Analysis of test diets	Mean found concentration [ppm] [a]	Mean found concentration [b] [%]	Average found concentration [b] [%]	RSD [%]
Dog diet	60	Week 1	60.5	100.8	96.2	4.2
		Week 13	59.5, 60.5	99.2, 100.8		
		Week 26	52.0, 55.6	86.7, 92.7		
		Week 28	58.2, 57.3	97.0, 95.5		
		Week 39	59.2, 58.2	98.7, 97.0		
		Week 52	57.0, 56.8	95.0, 94.7		
	120	Week 1	120	100.0	96.9	3.0
		Week 13	112, 113	93.3, 94.2		
		Week 26	116, 116	96.7, 96.7		
		Week 28	-/-	-/-		
		Week 39	119, 120	99.2, 100.0		
		Week 52	111, 119	92.5, 99.2		
	240	Week 1	234	97.5	99.4	1.8
		Week 13	242, 245	100.8, 102.1		
		Week 26	235, 238	97.9, 99.2		
		Week 28	-/-	-/-		
		Week 39	237, 238	98.8, 99.2		
		Week 52	245, 234	102.1, 97.5		

RSD = Relative standard deviation
[a] Mean of 3 measurements.
[b] Conversion of [ppm] to [%] was calculated using the data originating from the study report and by considering the respective nominal concentration; average concentration and RSD values are based on these calculations.

Specificity The identification and quantification of WL85871 were based on the selected wavelength at 220 nm, the retention time and the use of the internal standard butylated hydroxytoluene. Under the described conditions, the method is specific for the determination of WL85871 in dog diet. As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Interference No test substance was detected in the control diet samples.

Matrix Effects Matrix-matched calibration solutions were used for quantification of WL85871, hence any potentially occurring matrix effects were automatically accounted for as calibration standards and unknown samples contained identical matrix load.

Limit of Quantification The limit of quantification (LOQ) is defined by the lowest fortification level of 60 ppm for WL85871.

Limit of Detection	Good detectability is achieved at a signal to noise ratio of 3:1, which is defined as the limit of detection (LOD).
Repeatability	The relative standard deviation (RSD, %) for all concentration levels were < 20% for WL85871.
Reproducibility	The results in Table 4.1.2-27 are mean values of samples measured at different days. The data are comparable, so a reproducibility is given.
Conclusion	**The described method is suitable for the determination of WL85871 (active substance alpha-cypermethrin) in dog diet.**

Report: CA 4.1.2/23
Done J.N., 1984 a
Establishment of methodology for the analysis of WL 85871 in SDS dog diet (A) and the assessment of the dietary mixing procedures and the stability of WL 85871 in SDS dog diet (A)
AL-245-004
Guidelines: none
GLP: no

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Principle of the method

About 20 g of dog diet samples (SDS dog diet (A)) were weighed in a 250 mL glass screw top jar. 2 mL of the internal standard butylated hydroxytoluene (BHT) in acetone was added and then extracted with 50 mL acetone by mechanical shaking for 1 h at ambient temperature. Samples of the clear supernatant were taken for analysis.
Analysis was accomplished by reverse phase HPLC using UV detection at 220 nm. The chromatography was performed on a column packed with 3 µm ODS Hypersil, using a mixture of methanol/distilled water (70/25, v/v) as mobile phase with a flow rate of 2 mL/min.

Recovery findings

The described method is suitable to determine residues of WL85871 (active substance alpha-cypermethrin) in dog diet. 20 g and 100 g samples formulated with WL85871 at a concentration level of 200 ppm were taken from 3 levels (bottom, middle and top) in the mixing drum and analyzed. The results showed a homogeneous distribution and an overview is given in Table 4.1.2-31.

Additionally, the repeatability of the extraction procedure and the repeatability of the chromatography was tested by analyzing 10 samples from the same extract and this analysis was repeated once. The results showed excellent repeatability in both cases and the detailed results are summarized in Table 4.1.2-32.

Table 4.1.2-28: Results of the analysis of WL85871 in dog diet at 200 ppm

Matrix	Concen-tration [ppm]	Sample origin	Observed concentration [ppm]	Mean observed concentration [ppm]	Mean observed concentration [a] [%]	RSD [a] [%]
Dog diet (20 g samples)	200	bottom	184, 186, 191, 180, 178, 186	184	92	2.5
		middle	187, 205, 189, 187, 182, 186	189	95	4.2
		top	179, 194, 182, 184, 184, 184	185	92	2.7
Dog diet (100 g samples)	200	bottom	197, 195, 202	198	99	1.8
		middle	200, 203, 206	203	102	1.5
		top	204, 209, 209	207	104	1.4

RSD = Relative standard deviation
[a] Conversion of [ppm] to [%] was calculated using the data originating from the study report and by considering a nominal concentration of 200 ppm, RSD values are based on these calculations.

Table 4.1.2-29: Results of the analysis and repeat analysis of 10 samples of the extract from one diet

Matrix	Concen-tration [ppm]	Analysis	Observed concentration [ppm]	Mean observed concentration [ppm]	Mean observed concentration [a] [%]	RSD [a] [%]
Dog diet	200	Analysis of 10 samples	184, 182, 182, 189, 185, 186, 181, 180, 186, 185	184	92	1.5
		Repeat analysis of 10 samples	184, 181, 182, 183, 185, 183, 185, 181, 184, 186	183	92	0.9

RSD = Relative standard deviation
[a] Conversion of [ppm] to [%] was calculated using the data originating from the study report and by considering a nominal concentration of 200 ppm, RSD values are based on these calculations.

Specificity

The identification and quantification of WL85871 were based on the retention time, UV detection at 220 nm and the use of an internal standard. Under the described conditions, the method is specific for the determination of WL85871 in dog diet. As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Interference

Samples of blank diet showed no significant peaks at the retention times of WL85871 or the internal standard butylated hydroxytoluene.

Matrix Effects

Matrix-matched calibration solutions were used for quantification of WL85871, hence potentially occurring matrix effects were accounted for. Furthermore, the control sample / blank analysed did not show any eluting matrix at the elution time of interest.

Stability The diet samples were stored in the dark at room temperature and analyzed after 1, 10 and 21 days. The results showed stability over 10 days of storage, however, after 21 days of storage the results indicated a slight loss of WL85871 (Table 4.1.2-30).

Table 4.1.2-30: Results of the storage stability of WL85871 in dog diet

Matrix	Concen-tration [ppm]	Sample origin	Day of analysis	Observed concentration [ppm]	Mean observed concentration [ppm]	Mean observed concentration [a] [%]
Dog diet	200	bottom	Day 0	197, 195, 202	198	99
			Day 10	198, 206, 197	200	100
			Day 21	191, 189, 190	190	95
		middle	Day 0	200, 203, 206	203	102
			Day 10	200, 196, 198	198	99
			Day 21	194, 193, 182	190	95
		top	Day 0	204, 209, 209	207	104
			Day 10	198, 194, 197	196	98
			Day 21	189, 192, 189	190	95

[a] Conversion of [ppm] to [%] was calculated using the data originating from the study report and by considering a nominal concentration of 200 ppm.

Limit of Quantification The limit of quantification (LOQ) is defined by the used fortification level of 200 ppm for WL85871.

Limit of Detection Good detectability is achieved at a signal to noise ratio of 3:1, which is defined as the limit of detection (LOD).

Repeatability The relative standard deviation (RSD, %) for all concentration levels were < 20% for WL85871.

Reproducibility Reproducibility was not tested within the validation study.

Conclusion **The results show that the analytical methods is accurate and precise. Therefore, the described method is suitable for the determination of WL85871 (active substance alpha-cypermethrin) in dog diet.**

Report: CA 4.1.2/24
[redacted] 1984 a
WL 85871: 13 week oral (dietary) toxicity study in dogs
AL-425-005
Guidelines: none
GLP: yes
(certified by Department of Health and Social Security, London, United Kingdom)

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Remark: For concentration control experiments (see Table 4.1.2-34), the validated method of J.N. Done, 1984 [*AL-245-004*] was used. Under the described conditions, the analytical method was accurate and precise and therefore suitable to determine WL85871 (active substance alpha-cypermethrin) in dog diet.

Principle of the method

Homogeneity
The diet samples (18.7 to 20.0 g) were weighed into a cellulose extraction thimble and extracted with a mixture of hexane/acetone (2/1, v/v) in a Soxhlet extractor for 3 hours. After cooling, the extracts were diluted with 100 mL hexane. A portion of 1 mL of each extract was diluted with hexane to 100 mL.
Analysis was accomplished by gas-liquid chromatography equipped with an electron capture detector (ECD). The chromatography was performed on a glass column (3% (m/m) of OV 17 on 100 to 120 mesh Supelcoport) with nitrogen as carrier gas with a flow rate of 54 mL/min. An external standard solution of 96% pure WL85871 with a concentration of 0.0597 µg/mL was used for calibration.

Recovery findings

Dog diet samples formulated with WL85871 at concentration levels of 30 ppm, 90 ppm and 270 ppm were analyzed in the respective dose week (week 1, 6, 12 and additionally in week 7, 8, 9 at concentration level 30 ppm as reserve). The calculated average values of all samples were in the range between 93.3% and 96.5%. The detailed results are given in Table 4.1.2-31.

Furthermore, to test the homogenous distribution of the test substance in the diet samples, samples at a concentration level of 30 ppm WL85871 were analyzed in diet samples formulated for dose weeks 1, 6 and 12. For this purpose, duplicate samples were taken from different positions (bottom, middle and top) of the mix. The results of the analysis demonstrate that each of the diet samples contained WL85871 at a concentration close to the nominal concentration. Results are presented in Table 4.1.2-32.

Table 4.1.2-31: Results of concentration control of WL85871 in dog diet at concentration levels of 30 ppm, 90 ppm and 270 ppm

Matrix	Nominal concentration [ppm]	Gender male/female	Analysis of test diets [a]	Mean found concentration [b] [ppm]	Mean found concentration [c] [%]	Average found concentration [c] [%]	RSD [c] [%]

				Week 6	99		
				Week 12	102		

RSD = Relative standard deviation
[a] Mean of duplicates.
[b] Average found concentration and RSD values are based on calculations of the data originating from the study report.

Specificity The identification and quantification of WL85871 were based on the retention time and the use of an external standard. Under the described conditions, the method is specific for the determination of WL85871 in dog diet. As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Interference No test substance or interfering signal was detected in the diet control samples at the specific wavelength and elution time of the analyte.

Limit of Quantification The limit of quantification (LOQ) is defined by the lowest fortification level of 30 ppm for WL85871.

Limit of Detection Good detectability is achieved at a signal to noise ratio of 3:1, which is defined as the limit of detection (LOD).

Repeatability	The relative standard deviation (RSD, %) for all concentration levels were < 20% for WL85871.
Reproducibility	The results in Table 4.1.2-31 and Table 4.1.2-32 are mean values of samples measured at different days. The data are comparable, so a reproducibility is given.
Conclusion	**The described method is suitable for the determination of WL85871 (active substance alpha-cypermethrin) in dog diet.**

Report:	CA 4.1.2/25 [redacted] 1993 a WL85871 (Fastac): An acute oral (gavage) neurotoxicity study in the rat AL-451-004
Guidelines:	none
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Report:	CA 4.1.2/26 N.N. Except of raw data supporting analytical methods used in toxicological studies 2016/1232572
Guidelines:	not stated
GLP:	not stated

Report:	CA 4.1.2/27 N.N. Sittingbourne analytical method series determination of Fastac and the ratio of enantiomer pairs in technical material and formulated products liquid chromatographic method AL-210-001
Guidelines:	not stated
GLP:	not stated

An overview of the analytical procedure given below is done under the unique document identifier of the original toxicological study.

Principle of the method

The test substance FASTAC (active substance alpha-cypermethrin) was prepared by weighing a defined amount of the test substance in corn oil and diluting to the required volume. Solutions containing 0 and 0.6% m/v were supplied.
For stability experiments, 250 mL of a 0.6% m/v solution was prepared. The solution was divided into four 50 mL samples for dosing and one separate sample for analysis. In addition, 4 x 50 mL corn oil samples were used for control dosing. The samples were stored at room temperature in der dark.
For concentration control, 250 mL of a 0.6% m/v solution was prepared and divided as described above for stability experiments.
Analysis was accomplished using analytical method SAMS 490 (AL-210-001) by HPLC with ultraviolet absorption detection at 230 nm. HPLC analysis was done using a packed Spherisorb CN column equipped with a guard column and a mobile phase of n-hexane and MTBE (99.5 / 0.5 v/v) at a flow rate 3.0 mL/min at 22°C.

Recovery findings

The described method is suitable as concentration control for the determination of WL85871 (active substance alpha-cypermethrin) in solutions prepared in corn oil. Samples dosed with WL85871 at a concentration level of 6 mg/mL WL85871 were analyzed; two as received and two as pre-warmed samples. The mean of all analyzed samples was 90.2%, which is acceptable within the ±10% tolerance. The detailed results are given in Table 4.1.2-33.

Table 4.1.2-33: Results of concentration control of WL85871 in corn oil

Matrix	Sample set	Concentration [%]	Mean concentration [%]	Average concentration [%]	RSD [a] [%]
Corn oil	received	89.7, 89.7	89.7	90.2	1.0
	warmed	89.8, 91.6	90.7		

RSD = Relative standard deviation
[a] RSD value is based on calculations using data originating from the study report

Linearity Linearity is not stated in the report itself; however, calibration curves from the original raw data assessing the linearity of the detector response versus concentration (n=5 with single injection) confirmed good correlation, although the regression factor was not given in the raw data.

Specificity The identification and quantification of WL85871 were based on the analysis using HPLC with ultraviolet absorption detection (230 nm). Under the described conditions, the method is specific for the determination of WL85871 in corn oil. As the method is only used for dose verification of known substances and known nominal concentrations, no additional confirmatory technique is necessary.

Interference No test substance was detected in the corn oil control samples (< 0.003 mg/mL).

Matrix Effects No interference at the detection wavelength and retention times of interest were reported.

Limit of Quantification As the LOD is defined as at least 30% of the LOQ, the proposed LOQ of this method is 1.7 mg/mL. However, as no solid samples are extracted, but formulations were analyzed after dilution, no fortification experiments were conducted as not required.

Limit of Detection Good detectability is achieved at a signal to noise ratio of 3:1, which is defined as the limit of detection (LOD). The lowest standard was 0.5 mg/mL

Repeatability The relative standard deviation (RSD, %) for the tested concentration level was < 20% for WL85871.

Reproducibility Reproducibility of the method was not determined within the study.

Stability Data from the stability analysis indicated that the formulations were stable for four days and furthermore, that the isomerization ratio (cis I to cis II) in the formulations remained constant over the storage period. Results are presented in Table 4.1.2-34.

Table 4.1.2-34: Results of concentration control of WL85871 in corn oil

Matrix	Date of analysis	alpha-cypermethrin [mg/mL]	Isomer ratio	
			CIS I	CIS II
Corn oil	0 d	6.1	3	97
	4 d	5.9	3	97

Conclusion **The described method is suitable for the determination of WL85871 (active substance alpha-cypermethrin) in corn oil.**

(d)Methods in body fluids, air and any additional matrices used in support of operator, worker, resident and bystander exposure studies

No stand-alone validated analytical methods for the determination of alpha-cypermethrin were required for exposure studies.

(e)Methods in or on plants, plant products, processed food commodities, food of plant and animal origin, feed and any additional matrices used in support of residues studies

The following methods cover the compounds necessary for the discussion on the residue definition for risk assessment for products of plant and animal origin as summarized in Document N, chapter 7.3 and discussed in CA 6.7:

Plant: BAS 310 I [alpha-cypermethrin, Reg. No. 4078193]

Animal:
in milk and kidney: BAS 310 I [alpha-cypermethrin, Reg. No. 4078193]

in other animal matrices: BAS 310 I [alpha-cypermethrin, Reg. No. 4078193]

Plant

Analytical methods for the determination of alpha-cypermethrin residues in plant matrices were evaluated in the context of the inclusion in Annex I of Directive 91/414/EEC. Methods evaluated previously are listed in Table **4.1.2-35** and shortly summarized below. Methods not yet evaluated are summarized in detail in the following chapter.

Table 4.1.2-35: Summary of peer-reviewed analytical methods for determination of alpha-cypermethrin residues in plant matrices

Report:	CA 4.1.2/28 Anonymous, 1983 Determination of residues of Ripcord (WL 43467) in crops - Gas chromatographic method 1983/7001664
Guidelines:	not stated
GLP:	not stated

Method SAMS 383-1

Principle of the method

For analytical method SAMS 383-1, samples of homogenized crop are extracted and partitioned at the same time by macerating with a mixture of aqueous acetonitrile (1:1, v/v) and re-distilled petroleum spirit. The mixture is either allowed to stand (straw, fruit) or centrifuged (grain) to obtain phase separation, depending on the matrix. The organic phase is water washed, dried with sodium sulphate and cleaned up using a pre-washed Bond Elut-CN cartridge. Final determination is performed with GC on a glass column (1.4 m × 3.0 mm) with OV 201 2% (m/m) or polar phases such as GEXE60, OV225 and Ultrabond 20 M as stationary phase and nitrogen as mobile phase. An electron capture (EC) detector (^{63}Ni source) is used. GC-MS determination is performed on a glass column (1.5 m × 2.0 mm) with SE 30 1% (m/m) as stationary phase and helium as mobile phase. Mass spectrometric detection is performed in the negative ionization mode with m/z 207 and 209.

Recovery findings	Not reported.
Linearity	Not reported.
Specificity	The signal to noise ratio is 5:1. For confirmation, GC-MS determination can be performed on a glass column (1.5 m × 2.0 mm) with SE 30 1% (m/m) as stationary phase and helium as mobile phase. Mass spectrometric detection is performed after ionization (negative mode) with m/z 207 and 209.
Limit of Quantification	The limit of quantification for cypermethrin (RIPCORD; WL 43467) is 0.01 mg/kg for all investigated plant matrices.
Repeatability	The repeatability of this method was found to be 0.17 for milled grain containing 0.8 mg/kg cypermethrin (22 degrees of freedom) and 0.09 for milled grain containing 1.5 mg/kg alpha-cypermethrin (20 degrees of freedom).
Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.

Standard stability	Solutions of the test substance in hexane can be stored for at least three months at ambient temperature in the dark.
Conclusion	**The information given for the method number SAMS 383-1 indicates its suitability to determine cypermethrin residues in grain and other plant matrices.**

Report:	CA 4.1.2/29 Anonymous, 1977 Determination of residues of WL 43479 in crops 1977/7000275
Guidelines:	not stated
GLP:	not stated

Report:	CA 4.1.2/30 Cole E.R., Woodbridge A.P, 1979 The development of methods for the analysis of crops and soil for residues of WL 43467 (Ripcord) and WL 43479 (Talcord) 1979/7000414
Guidelines:	not stated
GLP:	not stated

Methods SAMS 233-1 and SAMS 234-1

Only data on cypermethrin (WL 43467; RIPCORD) are summarized below.

Principle of the method

Chopped or ground samples of aqueous based and non-oily crops (apples, grapes and maize grain and silage, lemon and kale) are extracted with a mixture of acetone and petroleum spirit (1:1, v/v). Extracts are washed with water to remove the acetone and are cleaned up by column chromatography on Florisil. Final analysis is performed with GC with electron capture (EC) detection. One of the following stationary phases has been used: OV-101, SE-30, Apiezon L, Oronite polybutene, DC-200 (grapes), OV-17, Reoplex 400, OV-210, OV-225 (other crops), Apolar 9CP or OV-275.

Extraction efficiency: Radiolabelled extractability studies and extraction of stored and aged samples carried out with cypermethrin (WL 43467, BAS 311 I) have shown the mixture of acetone and petroleum spirit to be an efficient solvent for the extraction of pyrethroid residues.

Recovery findings

The overall average recovery was 109%.There were no residues detected in the control samples above the limit of quantification (0.01 mg/kg). Individual recoveries ranged from 90 to 120%. Average recoveries for each matrix are summarised in Table **4.1.2-36**.

Table 4.1.2-36: Results of method validation: BAS 311 I (cypermethrin) in apple, maize, grape, lemon and kale specimens

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Apple	BAS 311 I	0.1	2	110	N/A	N/A
Maize grain	BAS 311 I	0.1	1	120	N/A	N/A
Maize silage	BAS 311 I	0.1	1	120	N/A	N/A
Grape	BAS 311 I	0.1	1	100	N/A	N/A
Lemon	BAS 311 I	0.1	1	90	N/A	N/A
Kale	BAS 311 I	0.1	1	110	N/A	N/A
Overall mean			**7**	**109**	**11**	**9.8**

Linearity	No data on linearity are presented in the report.
Specificity	Residues are confirmed by TLC on silica gel F_{254} plates followed by GC or GC-MS operating in the EI mode with multiple ion monitoring; ions m/z 163, 181 and 415 were monitored. Helium was used as carrier gas. No interference from co-extractives is usually observed.
Limit of Quantification	The limit of quantification (LOQ) for cypermethrin is 0.01 mg/kg for all investigated plant matrices.
Repeatability	The overall relative standard deviation (RSD, %) was below 20%. The detailed values are shown in Table **4.1.2-36**.
Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.
Standard stability	Stability of standards was not determined within this validation study.
Conclusion	**The method SAMS 233-1 is considered to be fit for purpose for the determination of residues of cypermethrin in apple, maize, grape, lemon and kale.**

Report:	CA 4.1.2/31 Klitsinaris A., 2000 Alphacypermethrin (AL 900049) 100 g ai/L OESC: Decline curve residue study on Alphacypermethrin in olives and olive oil - Hellas 1998 AL-714-002
Guidelines:	EEC 91/414 Annex II (Part A Section 6), EEC 91/414 Annex III (Part A Section 8),EEC 96/68,EEC 7029/VI/95 rev. 5
GLP:	not stated

Method AGROLABSOP-RAD.M004

Principle of the method

Olive oil is cleaned using gel permeation chromatography for the removal of lipids and other macromolecules. The fraction containing alpha-cypermethrin is collected and dried. The residue is diluted in n-hexane and further cleaned up through a Florisil column. Quantification is performed by GC-ECD.

Recovery findings

Average recoveries for all fortification levels were between 70 and 110%. Average recoveries for each matrix are summarised in Table **4.1.2-37**.

Table 4.1.2-37: Results of method validation: BAS 310 I (alpha-cypermethrin) in olive oil specimens

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Olive oil	BAS 310 I	0.020	3	82.1	3.2	3.9
		0.200	3	112.7	13.1	11.6
		1.000	2	97.6	2.8	2.8
Overall mean			**8**	**97.4**	**15.9**	**16.3**

Linearity	Linearity was tested using six calibration standards in the range of 0.002-0.080 mg/kg.
Specificity	A confirmatory method has not been performed; however, no interferences of matrix or labware have been reported. Good validation results have been achieved with the primary method.
Limit of Quantification	The limit of quantification (LOQ) for BAS 310 I is 0.02 mg/kg for olive oil.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-37**.

Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.
Standard stability	Stability of standards was not determined within this validation study.
Conclusion	**The method AGROLABSOP-RAD.M.004 is considered to be fit for purpose for the determination of residues of alpha-cypermethrin in olive oil.**

Report:	CA 4.1.2/32 Memmesheimer H., 1997 Alphacypermethrin (CL 900049): Analytical method for the determination of residues in savoy cabbage, leek and wheat grain AL-123-088
Guidelines:	not stated
GLP:	not stated

Method FAMS 045-02

Principle of the method

Alpha-cypermethrin is extracted from the sample with hexane/acetone (8:2, v/v). This is followed by liquid/liquid partitioning with water. The extract is evaporated to dryness. Further clean-up is achieved alternatively with solid phase extraction (savoy cabbage, leek) or gel permeation chromatography (wheat grain). Final analysis is performed by capillary gas chromatography with either a nitrogen/phosphorous (GC-NPD) or a mass selective detector (GC-MS) on a fused silica capillary column with methyl silicone as liquid phase and helium as carrier gas at a flow rate of 3.5 (NPD) or 0.85 mL/min (MSD). Mass spectrometric detection is performed after electron impact ionization (SIM mode) with m/z 165.

Recovery findings

Average recoveries for all fortification levels were between 70 and 110% using both the primary (GC-NPD) and the confirmatory method (GC-MS) for detection. Average recoveries for each matrix are summarized in Table **4.1.2-38** and Table **4.1.2-39**.

Table 4.1.2-38: Results of method validation: BAS 310 I (alpha-cypermethrin) in plant specimens – GC-NPD

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Savoy cabbage	BAS 310 I	Overall (0.01-0.5)	not reported	92	n.r.	7
Leek	BAS 310 I	Overall (0.01-0.5)	not reported	94	n.r.	6
Wheat grain	BAS 310 I	Overall (0.01-1.0)	not reported	85	n.r.	15

Table 4.1.2-39: Results of method validation: BAS 310 I (alpha-cypermethrin) in plant specimens – GC-MS

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Savoy cabbage	BAS 310 I	Overall (0.01-0.5)	not reported	91	n.r.	7
Leek	BAS 310 I	Overall (0.01-0.5)	not reported	93	n.r.	11
Wheat grain	BAS 310 I	Overall (0.01-1.0)	not reported	85	n.r.	3

Linearity Linearity was tested using calibration standards in the range of 0.05-2.0 µg/mL. Standard solutions are prepared in cyclohexanone.

Specificity For confirmation, either GC-NPD or GC-MS determination can be performed. No significant blank signals or unspecific interferences in untreated control samples were observed. The limit of detection is ≤50% LOQ (0.005 mg/kg).

Limit of Quantification The limit of quantification (LOQ) for alpha-cypermethrin is 0.01 mg/kg for all matrices tested.

Repeatability The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-38** and Table **4.1.2-39**.

Reproducibility Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.

Extract stability Stability of extracts was not determined within this validation study.

Standard stability Stability of standards was not determined within this validation study.

Conclusion **The method FAMS 045-02 is considered to be fit for purpose for the determination of residues of alpha-cypermethrin in cabbage, leek and wheat grain.**

Report:	CA 4.1.2/33 Memmesheimer H., 1996 Alphacypermethrin (CL900049): Validation of method FAMS 066-01 for the determination of CL 900049 residues in cereal grain and straw (Germany, 1996)
	AL-244-006
Guidelines:	IVA-Leitlinie Rueckstandsversuche Teil I (1992),BBA Guideline for the evaluation of pesticides for registration of a pesticide (Ribbesbuettel 2nd edition 1990),DFG Method Series for Pesticide Residue Analysis V and VIII (1991)
GLP:	Yes (Ministerium fuer Arbeit, Soziales, Familie und Gesundheit, Mainz, Germany)

Method FAMS 066-01

Principle of the method

For analytical method FAMS 066-01, samples of homogenized wheat grain and straw are extracted with hexane/acetone (8:2, v/v) and centrifuged. For clean-up the extracts were partitioned with water and the organic phase was reduced almost to dryness. The residue was dissolved in acidic methanol. Further clean-up was carried out by gel permeation chromatography. Final determination is performed with GC-NPD on a fused silica capillary column (12 m × 0.32 mm) with methyl silicone as liquid phase and helium as carrier gas at a flow rate of 3.5 mL/min.

Recovery findings

Average recoveries for all fortification levels were between 70 and 110% using both the primary (GC-NPD) and the confirmatory method (GC-MS) for detection. Average recoveries for each matrix are summarized in Table **4.1.2-40** and Table **4.1.2-41**.

Table 4.1.2-40: Results of method validation: BAS 310 I (alpha-cypermethrin) in wheat grain and straw specimens – GC-NPD

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Wheat grain	BAS 310 I	0.01	3	94	1.2	1.2
		0.10	3	74	2.1	2.8
		1.0	3	80	3.2	4.0
		Overall	9	82	9.1	11.1
Wheat straw	BAS 310 I	0.03	3	96	2.5	2.6
		0.30	3	82	2.0	2.4
		3.0	3	80	2.6	3.3
		Overall	9	86	8.0	9.3

Table 4.1.2-41: Results of method validation: BAS 310 I (alpha-cypermethrin) in wheat grain and straw specimens – GC-MS

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Wheat grain	BAS 310 I	0.01	3	93	1.2	1.2
		0.10	3	79	2.5	3.2
		1.0	3	76	1.0	1.3
		Overall	9	83	8.1	9.8
Wheat straw	BAS 310 I	0.03	3	100	5.7	5.7
		0.30	3	90	4.2	4.6
		3.0	3	77	2.6	3.4
		Overall	9	89	10.5	11.9

Linearity Linearity was tested using seven calibration standards in the range of 0.2-2 µg/mL. Calibration curves gave acceptable correlation coefficients ≥ 0.99. For grain and straw, cubic and linear curve fit were applied, respectively. Standard solutions are prepared in cyclohexanone.

Specificity For confirmation, GC-MS determination can be performed on a fused silica capillary column (12 m × 0.2 mm) with methyl silicone as liquid phase and helium as mobile phase at a flow rate of 0.85 mL/min. Mass spectrometric detection is performed after electron impact ionization (SIM mode) with m/z 165. No significant blank signals or unspecific interferences in untreated control samples were observed. The limit of detection is ≤30% LOQ (0.003 mg/kg for grain and 0.01 mg/kg for straw).

Limit of Quantification The limit of quantification (LOQ) for alpha-cypermethrin is 0.01 mg/kg for wheat grain and 0.03 mg/kg for wheat straw.

Repeatability The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-40** and Table **4.1.2-41**.

Reproducibility Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.

Extract stability Stability of extracts was not determined within this validation study.

Standard stability Stability of standards was not determined within this validation study.

Conclusion **The method FAMS 066-01 is considered to be fit for purpose for the determination of residues of alpha-cypermethrin in wheat grain and straw.**

Report:	CA 4.1.2/34 Atkinson S., 2002 Validation of the analytical procedure carried out for the analysis of Cypermethrin isomers in cabbage, carrots and lettuce carried out in study 83265
	AL-244-012
Guidelines:	none
GLP:	Yes (certified by Dempartment of Health of the Government of the United Kingdom, United Kingdom

Report:	CA 4.1.2/35 Cuthbert M., 1998 Analysis of Alphacypermethrin (AC 900049) in vining peas, field beans, strawberries, cherries and green beans
	AL-240-001
Guidelines:	none
GLP	not stated

Remark: Methods 12513.03.V, RLA 12644.01V are part of the document AL-244-012 which was submitted as part of the Addendum 2002. The data were initially not reported in the section of the analytical methods of the addendum 2002 because part of the residue study 83265 (CEMS-1691). In order to be complete, validation data are therefore presented here below.

The objective of the study was to demonstrate that the analytical procedure used in residue study 83265 may be used for quantitative analysis of cypermethrin isomers and to demonstrate the stability of the cis-2 isomer (alpha-cypermethrin) in crops.

Principle of the method:
The cabbage, carrot and lettuce specimens were extracted according to the analytical procedure described by BASF Agro Reasearch Procedure RLA 12513.03V “Analysis of Alphacypermethrin (AC 900049) in Vining Peas, Field Beans, Strawberries, Cherries and Green Beans”.
A 20g specimen was homogenized in 50/50 heptane/acetone, filtered and transferred to a round bottomed flask and evaporated to about 20mL. The extract was transferred to a separating funnel and water and heptane added. The specimen was partitioned into the heptane by inverting the funnel. The aqueous layer was removed. The heptane layer was portioned twice with water. The heptane was then collected through anhydrous sodium sulphate into a volumetric flask and made up to volume. An aliquot of the heptane was subjected to further clean up using silica solid phase extraction cartridges. All specimen matrices were analysed using conditions in the analytical procedure RLA 12644.01V. Final determination was by gas liquid chromatography with spectrometric detection. Detailed conditions are described in AL-240-001.

Specificity/Interference: Not demonstrated within the study report. However, GC-MS (RLS 12644.01V) is known to be a highly specific method by the possibility to monitor three m/z ions (see AL-244-009). Validation data were provided for the m/z ion 181.
Untreated control samples exhibit no significant interferences at retention time of the analytes (chromatograms were provided for all the analytes for matrix-matched standards, controls and fortified samples at LOQ and 10 × LOQ for the m/z ion 181).

Linearity: Typical results for a matrix matched calibration were provided for each analyte without indicating if it concerned calibration in cabbage, lettuce or carrots. The linearity response during the validation procedure was acceptable with a correlation coefficient > 0.995 for all analysis determination of the provided example. Seven matrix matched batch standard solutions over the range 0.005 – 0.15 µg/mL were injected. Regression equations and calibration curves were provided.

Recovery/Precision: see Table **4.1.2-42** and Table **4.1.2-43**

Limit of Quantification: 0.01mg/kg for each of the 4 isomers of cypermethrin in all matrices.

Table 4.1.2-42: Validation data (Atkinson, 2002)

Fortification Levels mg/kg	Cis I		Cis II		Trans III		Trans IV		Total isomers	
	Mean recovery %	% RSD	Mean recovery %	% RSD	Mean recovery %	% RSD	Mean recovery %	% RSD	Mean recovery %	% RSD

* A reference item solution of 0.005 µg/mL in matrix (equivalent to 0.005 mg/kg) was analysed with this batch thus demonstrating that this lower level is detectable. Therefore a recovery value of less than 70% has been accepted.
** method check
*** recovery data from procedural recoveries.

Conclusion: **The method is suitable to quantify the cypermethrin isomers at a limit of quantification of 0.01 mg/kg in crop matrices. The method has been used in support of a rotational crop study.**

Report:	CA 4.1.2/36 Young H., 2001 Confirmatory analysis of BAS 310 I (Alphacypermethrin) in cabbage, oilseed rape, barley grain and grapes using RLA 12644
	AL-244-010
Guidelines:	none
GLP:	Yes (certified by Dempartment of Health of the Government of the United Kingdom, United Kingdom

Principle of the method (RLA 12644.00 and RLA 12644.01 V issued method at the completion of the validation (RLA 12644.01V supersedes RLA 12644.00)):
Qualitative method RLA 12644 is used to confirm the specificity of method RLA 12642 (= DFG Method S19 (extended revision) – module D1) which was initially proposed for enforcement (cfr. addendum 1 dd. January 2001). The procedures for extraction and clean-up are the same as those outlined in RLA 12642, but an alternative detection method is used:

- extraction according to module E1 (grapes, cabbage) or E2 (grain) or E7 (oilseed rape)
- cleanup of extract using gel permeation chromatography (module GPC)
- supplemental cleanup using silica gel column chromatography (module C1)
- determination by capillary GC (Phenomenex Zebron ZB1; 30 m x 0.25 mm i.d.; 0.25 µ m) with MSD in SIM mode (monitoring ions m/z 163, 165 and 181)

Specificity/Interferences:	Specificity of method RLA 12642 (GC-ECD) is demonstrated by using GC-MS as an alternative method of detection. Samples were analysed in scan mode to obtain the retention time of the analyte and mass spectrum. The mass spectrum (full scan) was used to select the monitoring ions m/z 163, 165 and 181 and the resulting TIC was integrated. Untreated control samples exhibit no significant interferences at retention time of alphacypermethrin (control values < 20% of LOQ) (chromatograms were provided for matrix-matched standards, controls and fortified samples).
Linearity:	The response of the GC-MS system (= peak area) to alphacypermethrin was demonstrated to be linear over a concentration range from 0.01 to 0.1 µ g/mL (n = 5); r > 0.995 in all cases (matrix-matched calibration standards).
Recovery/Precision:	see Table **4.1.2-44**
Limit of Quantification:	0.01 mg/kg

Table 4.1.2-44: Validation of confirmatory method RLA 12644 (Young, 2001)

Matrix	Analyte	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
cabbage	Alpha-cypermethrin	0.01	3	72 – 103	86	18.4
oilseed rape		0.01	3	78 – 97	85	12.6
barley grain		0.01	3	65 – 80	71	11.2
grapes		0.01	3	90 – 94	92	2.3

Note: fortification with alpha-cypermethrin

Conclusion: **Method RLA 12644 (GC-MS) is suitable as confirmatory method to DFG Multi-residue Method S19 (extended revision) (GC-ECD) for determination of alphacypermethrin residues in plant matrices.**

Report:	CA 4.1.2/37 Author not specified, 1989 Determination of residues of Alphacypermethrin in crops - Gas chromatographic method AL-244-001
Guidelines:	none
GLP:	not stated

Report:	CA 4.1.2/38 Furr H., 1989 Certification of analysis: The determination of Fastac (WL 85871) residues in oilseed rape seed 1989/5000067
Guidelines:	none
GLP:	not stated

Principle of the method:
Crop samples are mixed with anhydrous sodium sulphate and extracted by homogenising with acetone/hexane (1:1 v/v). Extracts are washed with water to remove the acetone and in the case of oily crops (e.g. linseed, soybean, cotton seed and tobacco) the extracts are cleaned up by partitioning between hexane and water/acetonitrile (1:9 v/v). All extracts are cleaned up by liquid-solid chromatography using Florisil. Alpha-cypermethrin is determined by packed column GC (GE-XE 60 2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD); quantification by external standardization. Residues of alpha-cypermethrin are confirmed by capillary GC-ECD (SE-54; 0.5 µm) and GC-MS (SE-30 1% (m/m) on Gas Chrom Q (100-120 mesh)), MS operated in negative ion chemical ionisation mode (ions monitored: m/e 207 and 209).

Remark: SAMS 351-01 was also used in support of residue trials. Methods SAM 351-01 and SAM 351-02 do not differ (extraction procedure and analytical conditions). Description of method SAMS 351-01 is given in **DocID 1989/5000067** (Jones 1989 - *The determination of FASTAC (WL 85871) residues in oilseed rape seed* – Hazleton UK – HUK Project No. 717/1) submitted in the course of the assessment. Only slight differences in the chromatographic conditions (incl. packed column) occur.

Specificity/Interferences:	Typical packed column GC-ECD chromatograms are shown. Most control samples exhibit no major interfering peaks at the retention time of alpha-cypermethrin; control and blank data are < 0.01 mg/kg.
Linearity:	Not reported in this report. However, linearity is reported in DocID 1989/5000067 for analysis in oil seed rape seed (SAMS 351- 01). Calibration occurred solvent in the 0.002 – 0.1 µ g/mL (n = 5) and was linear (r = 0.9998, calibration curve and equation provided).
Recovery/Precision:	see Table **4.1.2-45**
Limit of Quantification:	The lowest fortified level is 0.05 mg/kg.

Table 4.1.2-45: Validation of method SAMS 351-02 (no author specified, 1989)

Matrix	Analyte	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
Apples (high water)	alpha-cypermethrin	0.05 0.20 0.50	2 2 2	95 - 110 95 - 105 90 - 110	102.5 100 100	(10.4) (7.1) (14.1)
		0.05 - 0.50	6	90 - 110	100.8	8.5
Wheat (dry – high starch)	alpha-cypermethrin	0.05 0.20 0.50	2 2 2	90 - 95 90 - 90 100 - 100	92.5 90 100	(3.8) (0.0) (0.0)
		0.05 - 0.50	6	90 - 100	94.2	5.2
Cabbage (high water)	alpha-cypermethrin	0.05 0.20 0.50	2 2 2	95 - 95 95 - 100 110 - 110	95.0 97.5 110	(0.0) (3.6) (0.0)
		0.05 - 0.50	6	95 - 110	100.8	7.3
Soybean (oily)	alpha-cypermethrin	0.05 0.20 0.50	2 2 2	85 - 100 75 - 90 85 - 95	92.5 82.5 90	(11.5) (12.9) (7.9)
		0.05 - 0.50	6	75 - 100	88.3	9.9
overall	alpha-cypermethrin	0.05 0.20 0.50	8 8 8	85 - 110 75 - 105 85 - 110	95.6 92.5 100	7.6 9.6 9.6
		0.05 - 0.50	24	75 - 110	96.0	9.2

Conclusion: **In terms of interfering blanks, accuracy (mean recoveries between 70 and 110%) and precision (RSD's lower than 20%), the method is suitable for alpha-cypermethrin residue analysis in dry, oily and aqueous based crops with a LOQ of 0.05 mg/kg.**

Report:	CA 4.1.2/1 Hitchings E., 1983 The development of methods for the determination of Ripcord - WL 44776 and WL 44607 in crops and soil AL-230-001
Guidelines:	none
GLP:	not stated

Methods SAMS 320-02 and SAMS 295-02

Principle of the method: The methods for both acid metabolites (WL 44776 = 2,2-dimethyl-3-(2,2- dichlorovinyl)cyclopropane carboxylic acid; WL 44607 = 3-phenoxybenzoic acid) are essentially the same.
Aqueous and dry crops are extracted by homogenizing with a mixture of water/acetonitrile to give a final solvent ratio of 30:70 v/v. The extract is filtered, after which an aliquot of the filtrate is diluted with water and partitioned under acidic conditions with a diethylether/petroleum spirit mixture (1:1 v/v), to extract any free WL 44776 (resp. WL 44607) present.
Oily crops are extracted by homogenizing with acetonitrile, after which the extract is filtered. An aliquot of the filtrate is concentrated to low volume, diluted with aqueous sodium carbonate and partitioned with petroleum spirit to remove oil and any parent pyrethroid which may be present. The resulting aqueous extract is diluted further with aqueous sodium chloride solution and is partitioned with diethyl ether/petroleum spirit (1:1 v/v) to remove any remaining traces of oil and other co-extractives. After acidification of the aqueous phase, free WL 44776 (resp. WL 44607) is extracted from the aqueous phase with diethyl ether/petroleum spirit (1:1 v/v).
Conjugated WL 44776 (resp. WL 44607) is hydrolyzed by concentrating the remaining aqueous phase under alkaline conditions and subsequently treating it with HCl. Any WL 44776 (resp. WL 44607) released is partitioned into diethyl ether/petroleum spirit (1:1 v/v). Residues of WL 44776 (resp. WL 44607) in the “free acid” or “hydrolyzed” extracts are cleaned up by normal phase HPLC (LiChrosorb Diol (10 µm); isocratic elution) with UV detection at 225 nm, after which WL 44776 (resp. WL 44607) is determined by reversed phase HPLC (Spherisorb S5 ODS (5 µm); isocratic elution) with UV detection at 216 nm; quantification by external standardization.
If the extracts are not sufficiently clean for satisfactory analysis to be carried out, the acid WL 44776 (as obtained after normal phase HPLC) may be converted into the parent WL 43467 (cypermethrin) by reaction with α-cyano-3-phenoxybenzyl bromide, after which the derivative is cleaned up using a Porasil column. Analysis is then carried out using GC (GE-XE 60 1.2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD).
The acid WL 44607 (as obtained after normal phase HPLC) may be converted into its methyl ester, after which the derivative is cleaned up by partition with petroleum spirit. Analysis is then carried out by either reversed phase

HPLC (ODS-Hypersil (5 µm); isocratic elution) with UV detection at 212 nm or GC-MS (SE-30 2% (m/m) on Gas Chrom Q (100-120 mesh)) with multiple ion monitoring (MS operated in EI mode, ions monitored : m/e 196 and 228). The latter procedure may also be adopted to confirm the identity of any residues found.

Residues of WL 44776 determined by HPLC may be confirmed by preparing the parent compound WL 43467 as described above and using either TLC-GC (GE-XE 60 1.2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD) or GC-MS (SE-30 1% (m/m) on Gas Chrom Q (100-120 mesh)) as the determination step, MS operated in EI mode (ions monitored : m/e 207 and 209).

Specificity/Interference: Typical HPLC chromatograms are shown. Most control samples exhibit no major interfering peaks at the retention time of the metabolites; blank values are stated to be < 0.05 mg/kg. Chromatograms of recovery extracts fortified with WL 44776 and WL 44607 at the same time were not shown, but based on the retention times that were stated, both metabolites should be well resolved under the test conditions used.

Recovery/Precision: see Table **4.1.2-46**

Limit of Quantification: Based on the recovery results that were submitted, a LOQ of 0.10 mg/kg seems appropriate for WL 44607 (free and conjugated), while for WL 44776 (free and conjugated), a LOQ of 0.50 mg/kg appears defensible.

Table 4.1.2-46: Validation of methods SAMS 320-02 and SAMS 295-02 (Hitchings at al., 1983)

Matrix	Analyte	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
Lettuce, potatoes, maize, apples, pears	WL 44776 free	0.20 0.50	1 4	80 70 - 100	- 80	- 16.9
		0.20 - 0.50	5	70 - 100	80	14.7
	WL 44766 conjugated	0.50	5	65 - 85	76	9.8
Cabbage, potatoes, maize, apples, pears	WL 44607 free	0.10 0.20 0.50	2 3 1	100 - 115 100 - 120 90	107.5 113.3 -	(9.9) 10.2 -
		0.10 - 0.50	6	90 - 120	107.5	11.7
	WL 44607 conjugated	0.10 0.50	2 4	85 - 100 60 - 105	92.5 85	(11.5) 22.0
		0.10 - 0.50	6	60 - 105	87.5	17.8

Conclusion: **In terms of interfering blanks, accuracy (overall mean recoveries between 70 and 110%) and precision (overall RSD's lower than 20%), the method appears suitable for WL 44776 (free and conjugated) residue analysis in crops with a LOQ of 0.50 mg/kg. The methods were however not considered by the residue section in the frame of the renewal and are no longer considered as relied upon.**

Report:	CA 4.1.2/39 Smalley R., 2002 Validation of method RLA 12644 for the analysis of Cypermethrin isomers in wheat straw and grain AL-244-011
Guidelines:	none
GLP:	not stated

Principle of the method:
The residues of BAS 310 I are extracted using acetone followed by liquid-liquid partitioning into ethyl acetate/cyclohexane. The extract is then further cleaned up using GPC followed by silica SPE cartridge prior to analysis by GC-MSD (m/z ions 163, 165 and 181, TIC integrated).

Specificity/Interferences:	Not demonstrated within the study report. However, GC-MS is known to be a highly specific method by the possibility to monitor three m/z ions (see Study No. 7 here above). Untreated control samples exhibit no significant interferences at retention time of the analytes (chromatograms were provided for matrix-matched standards, controls and fortified samples at LOQ and 10 × LOQ).
Linearity:	Typical results for matrix matched calibrations were provided for each analyte. The linearity response during the validation procedure was acceptable with a correlation coefficient > 0.995 for all analysis determinations. Five (for wheat straw) and four (for wheat grain) matrix matched batch standard solutions over the range 0.01 – 0.1 µg/mL were injected.
Recovery/Precision:	see Table **4.1.2-47**
Limit of Quantification:	0.01mg/kg (nominal) for each of the 4 isomers of cypermethrin in all matrices. The actual lowest fortification per isomer is lower than 0.01 mg/kg in function of the isomeric ratio.

Table 4.1.2-47: Validation data (Smalley 2002)

Fortification Levels mg/kg	Cis I		Cis II		Trans III		Trans IV		Total isomers	
	Mean recovery %	% RSD	Mean recovery %	% RSD	Mean recovery %	% RSD	Mean recovery %	% RSD	Mean recovery %	% RSD
Wheat straw (no group)										
0.01	84	7.1	75	10.5	82	6.8	91	12.2	83	8.8
0.1	106	7.4	110	9.2	114	9.8	118	6.8	112	6.1
Wheat grain (dry)										
0.01	78	6.0	69	8.6	80	9.3	78	7.0	77	5.7
0.1	92	3.9	98	7.8	90	5.1	97	2.8	94	2.7

* Note: fortification performed with mixed isomers. The fortification level stated corresponds to the sum of the cis or trans-isomers, hence 0.01 and 0.1 mg/kg are the nominal levels. The level per individual isomer needs to be corrected by the isomeric ratio. The isomeric ratio of the Cis-I-Cis-II in the corresponding cypermethrin standard and the isomeric ratio of Trans-III-Trans-IV in the corresponding cypermethrin standard was however not availavle within the study.The actual lowest fortification per isomer is hence lower than 0.01 mg/kg. n = 5 replicates at each fortification level and for each analyte.

Conclusion: **This data generation method has been used in support of a cereal rotational crop study. As the results obtained generally lead to an overestimation of the residues determined, this method is considered to fully support the data generated.**

Report:	CA 4.1.2/40 Smalley R., 2002 Method validation of RLA 12594.01 analysis of Alphacypermethrin (AC 900049) in olives and olive oil AL-244-007
Guidelines:	EEC 91/414 Annex II (Part A Section 6), EEC 91/414 Annex III (Part A Section 8), EEC 96/98
GLP:	Yes (Department of Health of the United Kingdom, United Kingdom)

Report:	CA 4.1.2/41 Anonymous, 2016 Excerpt of raw data supporting analytical methods used for the analysis of plant & animal matrices 2016/1232571
Guidelines:	not stated
GLP:	not stated

Method RLA 12594.01

Note: The method RLA 12594.01 (AL-244-007) was used as analytical method in residue study AL-750-038 (addendum 2002)- Alpha-cypermethrin 150 g as/kg WG(RLM 11203): A harvest residue study on alphacypermethrin in oil seed rape, south France, 2000 (KII 6.3/011), Grolleau G. The data were initially not reported in the section of the analytical methods of the addendum 2002 because part of the residue study AL-750-038. In order to be complete, validation data are therefore presented here below.

Method RLA 12594.02V supersedes RLA 12594.01 (method was amended only for calculation due to change in the volume used for extraction). The study reported results obtained for the primary validation but also for independent laboratory validation.

Principle of the method:

A 10 g specimen portion was extracted two times with acetonitrile. The acetonitrile was partitioned three times with hexane. An aliquot of the acetonitrile is evaporated and reconstituted in heptane. Clean-up was achieved by solid phase extraction using silica cartridges. Analysis was then performed by GC-ECD (DB5 column, 15 m × 0.53 mm i.d., 0.5 µm film thickness, oven temperature: 50°C for 0.5 min., then 35°C/min. to 200°C, then 10°C/min. to 280°C, hold 4 min.). External calibration.

Specificity/Interferences:	The report stated that specificity of method RLA 12594.01 (GC-ECD) was demonstrated by using GC-MS as an alternative method of detection. However, no results were provided. Untreated control samples exhibit no significant interferences at retention time of alpha-cypermethrin (chromatograms were provided for standards, controls and fortified samples at LOQ and 10 × LOQ).

Linearity: The linearity response during the validation procedure was acceptable with a correlation coefficient > 0.995. Five standard solutions over the range 0.02 – 0.1 µg/mL (40 – 200% of the normal working standard concentration, corresponding to 0.04 – 2 mg/kg) were injected. Calibrations occurred in solvent whereas matrix effects were not assessed in the study report. *Matrix was removed by the extensive clean-up using liquid-liquid partitioning of the acetonitrile phase with hexane. Untreated specimen confirm the absence of interference (example chromatograms in the study report)*". Additionally, **DocID 2016/1232571** (excerpt of raw data supporting analytical methods used for the analysis of plant & animal matrices) provided during the course of the assessment, that the ion ratios of all ions were comparable in the samples and standards (when confirmation by GC-MS), hence indicating that matrix-effects can be excluded (calibration with MS detection in the 0.02 – 0.1 µg/mL range).

Matrix effects: Matrix was removed by the extensive clean-up using liquid-liquid partitioning of the acetonitrile phase with hexane. Untreated specimen confirm the absence of interference (example chromatograms in the study report)". Additionally, **DocID 2016/1232571** (excerpt of raw data supporting analytical methods used for the analysis of plant & animal matrices) provided during the course of the assessment, that the ion ratios of all ions were comparable in the samples and standards (when confirmation by GC-MS), hence indicating that matrix-effects can be excluded (calibration with MS detection in the 0.02 – 0.1 µg/mL range).

Recovery /Precision: see Table **4.1.2-48**

Limit of Quantification: 0.05 mg/kg for alpha-cypermethrin in both matrices.

Table 4.1.2-48: Primary and independent validation data (Smalley 2002)

Sample matrix.	Fortification level (mg/kg)	Recovery (%)		RSD (%)	n
		Individual	Mean		
Olive oil (primary validation)	0.05	77, 74, 98, 76, 84	82	12	5
	1.0	83, 81, 80, 81, 80	81	2	5
Olive (primary validation)	0.05	88, 107, 80, 81, 76	86	14	5
	1.0	67, 61, 71, 68, 69	**67**	6	5
Olive oil (independent validation)	0.05	84, 84, 80, 80, 81	82	3	5
	1.0	88, 90, 91, 91, 89	90	1	5
Olive (independent validation)	0.05	73, 104, 80, 108, 87	90	17	5
	1.0	75, 77, 75, 76, 77	76	1	5

Conclusion:	**Mean recoveries and RSD were within the acceptable limits (70 -110 % and < 20%) at the LOQ and higher fortification level for oil and olive oil except for olive at the higher level (1.0 mg/kg) where the mean recovery was slightly below 70% with an acceptable RSD. Independent laboratory validation was performed. The method can be considered to be "fit for purpose" to support residue trials in the case of the determination of alpha-cypermethrin at 0.05 and 1.0 mg/kg in olive oil and at 0.05 mg/kg in olive. Since the ILV confirmed acceptable results at 0.05 mg/kg and residue levels obtained in study AL-HE-99-530 (trial 99-530-01 referring to residue trial in olive – Trewhitt, 1999a, AL-714-001 – DocID 2000/7000996, the method is considered suitable for the quantification of alpha-cypermethrin in seeds, oil and press cake.**

Report:	CA 4.1.2/42 Walker B., Linkerhaegner M., 2000a Alphacypermethrin (AC900049): Validation of the DFG method S 19 (extended revision) for the determination of residues of Alphacypermethrin in/on grapes wheat grain cabbage and oilseed rape AL-244-008

Report:	CA 4.1.2/43 Walker B., Linkerhaegner M., 2000b Alphacypermethrin (AC 900049): Validation of the DFG method S 19 (extended revision) for the determination of residues of Alphacypermethrin in processed fractions of cabbage and oilseed rape AL-244-009
Guidelines:	E EEC 91/414, EEC 96/46 4.2.1,SANCO/825/00 rev. 6 (20 June 2000),BBA Guideline Residue Analytical Methods for Post-Registration Control Purposes of July 21 1998,EPA 860.1340
GLP:	Yes (Behoerde fuer Arbeit, Gesundheit und Soziales, Freie und Hasestadt Hamburg, Hamburg, Germany)

Method: DFG S19 used in support of residue trials / processing studies

Principle of the method: DFG method S19 (extended revision):

- Multimethod L 00.00-34 of the Official Collection of Test Methods according to §35 LMBG with extraction according to module E1 (grapes, cabbage and processed cabbage) or E2 (wheat grain) or E7 (oilseed rape and oilseed rape press cake) or E6 (refined rapeseed oil)
- cleanup of extract using gel permeation chromatography (module GPC)
- supplemental cleanup using silica gel column chromatography (module C1)
- determination by capillary GC (DB1; 30 m x 0.25 mm i.d.; 0.25 µm) with ECD (module D1)

Specimen material (e.g. grapes, cabbage and wheat grain) is extracted with acetone. Water is added beforehand in an amount that takes full account of the natural water content of the specimen so that during extraction the acetone:water ratio remains constant at 2:1 (v:v). For liquid-liquid partition ethyl acetate/cyclohexane (1+1) and sodium chloride are added and after mixing excess water is separated. Fat or dry, high fat specimen material (e.g. oilseed rape) is intensively mixed with a suspension of synthetic calcium silicate in acetonitrile and acetone. The suspension is filtered and the volume of the filtrate (organic phase) is measured. The organic phase is evaporated and the residue dissolved in the GPC elution mixture. The evaporated residue of an aliquot of the organic phase is cleaned up by gel permeation chromatography on Bio Beads S-X3 polystyrene gel using a mixture of ethyl acetate/cyclohexane (1+1) as eluent. The residue-containing fraction is concentrated and after supplemental silica gel mini column chromatography analysed for residues of alphacypermethrin by gas chromatography using an electron capture detector (ECD) (DB-1, 30 m × 0.25 mm, 0.25 µ m). Plant and animal fat (e.g. rapeseed oil) is dissolved in the GPC elution mixture. An aliquot is cleaned up by gel permeation chromatography on Bio Beads S-X3 polystyrene gel using a mixture of ethyl acetate/cyclohexane (1+1) as eluent. The residue-containing fraction is concentrated and after supplemental silica gel mini column chromatography analysed for residues of alphacypermethrin be gas chromatography using an electron capture detector (ECD).

Specificity/Interferences: Representative chromatograms (standards, control, fortified samples) are shown; untreated control samples exhibit no significant interferences.

Linearity: The response of the GC-ECD system (= peak area) to alpha-cypermethrin was demonstrated to be linear (r = 0.9995) over a concentration range from 0.0010 to 1 µg/mL (n = 7). Calibration in toluene.

Recovery/Precision : Table **4.1.2-49**

Limit of Quantification: 0.01 mg/kg

Table 4.1.2-49: Validation of DFG S19 (extended revision)

Matrix	Analyte (fortification)	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)

Report:	CA 4.1.2/45 Rabe U., Schweda Z., 2003 Technical procedure: Method for the determination of BAS 310 I in plant matrices 2003/1001290
Guidelines:	not stated
GLP:	not stated

Method 546/0

Principle of the method

Alpha-cypermethrin is extracted with a mixture of methanol/water/hydrochloric acid (70:25:5). An aliquot of the extract is centrifuged and cleaned by liquid/liquid partition against cyclohexane. The organic phase is purified by solid phase extraction (SPE) on a silica gel column. The final determination of BAS 310 I is performed by HPLC-MS/MS on a YMC J'sphere L80 column with an acidified water/methanol gradient as mobile phase at a flow rate of 0.6 mL/min. Ionization was performed in the positive mode and ion transitions 416 → 191 (primary) and 418 → 193 (confirmatory) were monitored.

Recovery findings

Average recoveries over both fortification levels were between 70 and 110% using both the primary and the confirmatory transition for detection. The recovery data are corrected for interference from matrix compounds of the appropriate unfortified sample (primary transition: ±0.4-4.7% for wheat forage, ±0.9-8.7% for wheat grain, ±0% for wheat straw, oilseed rape whole plant and grape fruit, ±0.2-2.7% for oilseed rape seed, ±1.0-9.9% for orange fruit; confirmatory transition: ±2.0-20.6% for wheat forage, ±1.3-13.6% for wheat grain, ±0% for wheat straw, oilseed rape whole plant, oilseed rape seed and grape fruit, ±0.1-4.4% for orange fruit).
Average recoveries for each matrix are summarized in Table **4.1.2-50**.

Table 4.1.2-50: Results of method validation: BAS 310 I (alpha-cypermethrin) in wheat, oilseed rape, grape and orange specimens

Matrix	Analyte	m/z	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Wheat forage	BAS 310 I	416 → 191	0.05	5	96.5	7.8	8.1
			0.5	5	103.8	4.4	4.2
Wheat grain	BAS 310 I	416 → 191	0.05	5	92.3	4.3	4.7
			0.5	5	93.1	4.8	5.2
Wheat straw	BAS 310 I	416 → 191	0.05	5	97.6	4.1	4.2
			0.5	5	95.7	4.4	4.6
Oilseed rape whole plant	BAS 310 I	416 → 191	0.05	5	106.5	8.3	7.8
			0.5	5	91.8	4.0	4.4

			0.5	4	93.6	7.0	7.5
Orange fruit	BAS 310 I	416 → 191	0.05	5	89.4	5.7	6.4
			0.5	5	101.2	5.4	5.3
Wheat forage	BAS 310 I	418 → 193	0.05	5	86.2	9.5	11.0
			0.5	5	98.4	4.9	5.0
Wheat grain	BAS 310 I	418 → 193	0.05	5	86.7	5.9	6.8
			0.5	5	91.1	3.7	4.1
Wheat straw	BAS 310 I	418 → 193	0.05	5	94.1	5.8	6.2
			0.5	5	92.4	4.7	5.0
Oilseed rape whole plant	BAS 310 I	418 → 193	0.05	5	114.3	10.0	8.8
			0.5	5	96.8	5.2	5.4
Oilseed rape seed	BAS 310 I	418 → 193	0.05	5	90.1	7.5	8.4
			0.5	5	90.4	4.0	4.4
Grape fruit	BAS 310 I	418 → 193	0.05	5	98.1	9.0	9.2
			0.5	4	96.1	5.2	5.4
Orange fruit	BAS 310 I	418 → 193	0.05	5	95.2	11.7	12.3
			0.5	5	100.3	2.5	2.5

Linearity Linearity was tested using six calibration standards in the range of 0.25-10 ng/mL (0.25-10 mg/kg). Calibration curves gave acceptable correlation coefficients ≥ 0.99. Standard solutions are prepared in methanol.

Specificity Quantification was performed by use of highly selective LC-MS/MS detection. Two selected ion mass transitions were evaluated in order to demonstrate that the method achieves a high level of selectivity. Residues and chromatographic signal interference in all blank control specimens were below the LOQ.

Limit of Quantification The limit of quantification (LOQ) for BAS 310 I is 0.05 mg/kg for all investigated plant matrices.

Repeatability The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-50**.

Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.
Standard stability	Stability of standards was not determined within this validation study.
Conclusion	**The method 546/0 is suitable for the determination of residues of alpha-cypermethrin in wheat (forage, grain, straw), oilseed rape (whole plant, seed), grape (fruit) and orange (fruit).**

Report:	CA 4.1.2/46 Anonymous, 2006 Residue behaviour of Alpha-Cypermethrin in/on fennel, curly cale, cucumbers, carrots, radies, celery, celeriac and bunshing or green onions after outdoor application of Fastac SC (SC 100) in Germany, 2005 2006/1029533
Guidelines:	not stated
GLP:	not stated

Method SAA/C/PSM02.3

Principle of the method

Alpha-cypermethrin is extracted from homogenized plant material with a mixture of methanol/water/2 N hydrochloric acid (70:25:5). An aliquot of the extract is centrifuged and cleaned by liquid/liquid partition against cyclohexane. The cyclohexane is evaporated and the organic phase is re-diluted in methanol/water (80:20, v/v). The final determination of BAS 310 I is performed by LC-MS/MS Ion transitions 433 → 191 (primary) and 435 → 193 (confirmatory) were monitored.

Recovery findings

Average recoveries for each fortification level were between 70 and 110%. Average recoveries for each matrix are summarized in Table **4.1.2-51**.

Table 4.1.2-51: Results of method validation: BAS 310 I (alpha-cypermethrin) in cucumber specimens

Matrix	Analyte	m/z	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Cucumber	BAS 310 I	433 → 191 435 → 193	0.005	n.r.	92	n.r.	5.2
			0.01	n.r.	95	n.r.	4.0
			0.1	n.r.	97	n.r.	2.7

Linearity	Linearity was tested using six calibration standards in the range of 0.05-5.00 ng/mL. Standard solutions are prepared in methanol/water (80:20, v/v) from stock solutions prepared in acetone.
Specificity	Quantification was performed by use of highly selective LC-MS/MS detection. Two selected ion mass transitions were evaluated in order to demonstrate that the method achieves a high level of selectivity.
Limit of Quantification	The limit of quantification (LOQ) for BAS 310 I is 0.005 mg/kg for all investigated plant matrices. The limit of detection (LOD) is 0.001-0.0036 mg/kg.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-51**.

Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.
Standard stability	Stability of standards was not determined within this validation study.
Conclusion	**The method SAA/C/PSM 023 is considered to be fit for purpose for the determination of residues of alpha-cypermethrin in cucumber. The report indicates that the method is equivalent to analytical method 567/0, which was fully validated (see 2005/5000063, CA 4.1.2/49).**

Report:	CA 4.1.2/47 Stewart J., 2005a Method validation of BASF analytical method 567/0 entitled: Method for determination of Alphacypermethrin and Cypermethrin in plant matrices - Including standard stability and extract stability 2005/5000063
Guidelines:	EPA 860.1340, SANCO/825/00 rev. 6 (20 June 2000)
GLP:	yes (certified by United States Environmental Protection Agency)

Principle of the method

The analytical procedure described was developed to identify the residues of BAS 310 I (alpha-cypermethrin) and BAS 311 I (cypermethrin) in plant matrices. Fortified plant samples were analysed using BASF Analytical Method 567/0. BAS 310 I (alpha-cypermethrin) or BAS 311 I (cypermethrin) are extracted with a 70:25:5 methanol/water/hydrochloric acid mixture from matrices except from commodities with high fat content. After centrifugation, an aliquot of the extract is partitioned into cyclohexane. Silica Gel SPE column is used for further purification, if required (for example for wheat straw). Final determination is performed by LC-MS/MS using the ammonium adducts of cypermethrin. From matrices of commodities with high fat content, BAS 310 I (alpha-cypermethrin) or BAS 311 I (cypermethrin) is extracted with acetonitrile/n-hexane. After centrifugation and further partitioning with n-hexane, an aliquot of the acetonitrile phase is removed. Silica Gel SPE column is used for further purification, if required. Final determination is also performed by LC-MS/MS using the ammonium adducts of cypermethrin.

Recovery findings

BASF Analytical Method 567/0 was successfully validated for all eight plant matrices tested. Average recoveries over both fortification levels ranged from 82.8 to 112.9% using the primary transition (m/z 433 → m/z 191) for detection. Coefficients of variation (%RSD) for the average recoveries were all less than 20%. There were no residues detected in the control samples above the limit of detection, except in the secondary transition of one of the orange samples (0.001 m/kg – at the limit of detection).
Individual recoveries ranged from 71 to 121% using the primary transition for detection. One laboratory outlier was not included in the statistical analysis. Results obtained using the secondary transition for detection (435 → m/z 193) were comparable to those obtained using the primary transition.
Average recoveries for each matrix are summarised in Table **4.1.2-52**.

Table 4.1.2-52: Results of method validation: BAS 310 I (alpha-cypermethrin) and BAS 311 I (cypermethrin) in wheat, tomato, orange cotton, pea and potato specimens

* Analysis conducted with optional clean-up column

Linearity	Calibration curves gave acceptable correlation coefficients ≥ 0.99.
Specificity	The method is specific for the determination of alpha-cypermethrin in plant matrices down to a level of 0.01 mg/kg.
Limit of Quantification	The limit of quantitation for BAS 310 I is 0.01 mg/kg for all investigated plant matrices.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-52**.
Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study
Extract stability	Recoveries obtained from stored grain and straw extracts did not diminish over the seven day storage period.
Standard stability	Recoveries obtained from stored chromatographic standard solutions of alpha-cypermethrin in acetonitrile/water (80:20 v,v) did not diminish after 33 days storage. The stock solution prepared in pure solvent (acetonitrile) was found to be stable for 94 days.
Conclusion	**The method 567/0 is suitable for the determination of residues of alpha-cypermethrin in wheat grain, wheat plant, wheat straw, tomato, orange, cotton seed, succulent pea and potato.**

Report: CA 4.1.2/48
Bretz M., 2007a
Technical procedure: Method for the determination of Alphacypermethrin in plant matrices by GC-MS - BASF method number 567/1
2007/1010254
Guidelines: none
GLP: no

Principle of the methods

BASF Method No 567/1 is an adaption of BASF Method No. 567/0 for the determination of alpha-cypermethrin and cypermethrin in various plant matrices. Data contained in the report on the technical procedure were not necessarily produced under GLP regulations. The document described in detail, is a technical procedure and no full validation report.
BAS 310 I (alpha-cypermethrin) is extracted with a 70:25:5 methanol/water/hydrochloric acid or a 95:5 methanol/hydrochloric acid mixture, depending on the matrix. After centrifugation, an aliquot of the extract is partitioned into cyclohexane. A Silica Gel SPE column is used for further purification, if required. Final determination is performed by GC-MS monitoring the three most intense ions. The two isomer peaks are determined together.

Recovery findings

Recoveries in barley matrices were determined in the context of the barley processing study 2007/1013068 (see Section 6, Point CA 6.5.3/2). All recovery data were determined under GLP and are reported in detail in DocID 2007/1013068.

The overall average recovery for all matrices over all fortification levels of BAS 310 I was 94.3% (%RSD = 12.0). Average recoveries for each matrix ranged from 82% (%RSD = 7.9) to 108% (%RSD = 3.8) and are summarised in Table **4.1.2-53**.

Table 4.1.2-53: Recoveries of alpha-cypermethrin in barley matrices

Crop	Matrix	Test Substance	Fortific. Level (mg/kg)	No. of Tests	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Barley	plant w/o root	BAS 310	0.1	5	100.7	8.5	8.4
			1.0	5	91.9	12.7	13.8
	malt culms	BAS 310	0.01	5	96.5	12.4	12.8
			0.1	5	82.0	6.5	7.9
	spent grain	BAS 310	0.1	5	91.0	12.8	14.1
	spent hops	BAS 310	0.01	4	93.1	10.8	11.6
			0.1	5	84.7	13.3	15.7
	yeast	BAS 310	0.01	5	108.0	4.1	3.8
			0.1	5	93.8	7.1	7.6
	beer	BAS 310	0.01	5	103.9	4.0	3.8
			0.1	5	86.5	6.6	7.7
	flour	BAS 310	0.1	5	99.2	5.4	5.4
			1.0	5	94.5	13.0	13.7
Overall mean				**64**	**94.3**	**11.3**	**12.0**

Linearity	Since the report describes the technical procedure, the linearity was not determined. However, in a residue report (BASF DocID 2009/1125197, see chapter 6.3) the detector response was reported to be linear within the range from 0.2 ng/mL to 70 ng/mL with a correlation coefficient >0.998.
Specificity	The GC-MS final determination for BAS 310 I is a highly selective detection. Three separate ions are monitored, one of which can be used for quantitative evaluation. The other ones can be used for confirmation of residue findings. Therefore no confirmatory technique is required.
Limit of Quantification	The limit of quantitation for BAS 310 I is 0.01 mg/kg for all investigated plant matrices.
Repeatability	For the plant matrices the relative standard deviations were below 20 % (4-16%).
Reproducibility	Reproducibility of the method was not determined.
Standard stability	Standards of BAS 310 I have been shown to be stable for up to 59 days in acetone and 62 days in acetone/H_20 (96/4) + 1 mg/ml L-gulono-ɤ-lacton.
Conclusion	**The successful validation of the method demonstrated that the BASF method number 567/1 is suitable to determine alpha-cypermethrin residues in barley and different processing matrices.**

Animal

Analytical methods for the determination of alpha-cypermethrin residues in animal matrices were evaluated in the context of the inclusion in Annex I of Directive 91/414/EEC. Methods evaluated previously are summarized in Table **4.1.2-54** for the reviewer´s convenience.

Table 4.1.2-54: Summary of peer-reviewed analytical methods for determination of alpha-cypermethrin residues in animal matrices

Method No.	Matrix	Method principle	Target analytes	LOQ mg/kg	year	DocID	EU reviewed
SAMS 461-01	Muscle, fat, kidney, liver	GC-ECD; GC-MS for confirmation	Alpha-cypermethrin	0.01	1988	AL-245-001	Yes
SAMS 456-01	Milk	GC-ECD; GC-MS for confirmation	Alpha-cypermethrin	0.001 mg/L	1988	AL-245-003	Yes
SAMS 461-1; SAMS 456-1	Muscle, fat, kidney, liver Milk	GC-ECD; GC/MS for specifity	Alpha-cypermethrin	0.05 0.01	1999	AL-245-006	Yes
DFG S 19	Milk, eggs	GC-ECD; GC-MS for confirmation GC/NPD as alternative determination method	Alpha-cypermethrin	0.01	2000	AL-245-007	Yes
DFG S 19	Blood and urine (Swine)	GC-ECD	Alpha-cypermethrin	0.005 mg/L	2000	AL-245-008	Yes
M 3499	Blood	GC-MS	Alpha-cypermethrin	0.005 mg/L	2001	AL-210-012 and RES 00-052 (AL-440-018)	No

Although already peer-reviewed during the previous Annex I-registration process, the previously submitted methods are summarised below for completeness of information.

The following method was not mentioned in the application but is also included in this dossier for completeness:
Method M3466 for determination of alpha-cypermethrin in hen egg had been validated as part of a poultry feeding study. A detailed description of the method is given in document M, chapter 6.4.1, Report CA 6.4.1/1 [redacted] 2001). Method 3466 as part of the respective poultry feeding study was not peer-reviews under directive 91/414*EEC earlier, as the entire study was regarded as not required due to an anticipated feed burden below the trigger value. Hence, method M3466 is not regarded as peer-reviewed and is described in detail in chapter CA 6.4.1/1 as part of the respective residue trial/feeding study.

Report:	CA 4.1.2/49 Anonymous, 1988 Determination of residues of Alphacypermethrin in animal tissues - Gas liquid chromatographic method AL-245-001
Guidelines:	not stated
GLP:	not stated

Principle of the method :
Tissue samples are chopped or minced finely, mixed with anhydrous sodium sulphate and extracted by boiling with acetone/hexane (1:2 v/v). The solvent is evaporated and the residue is re-dissolved in hexane. For fat and muscle samples, a portion of the extract is partitioned with acetonitrile by using an Extrelut extraction cartridge, while a normal hexane/acetonitrile partition is used for the liver and kidney extracts. All extracts are further cleaned up by liquid-solid chromatography on a Florisil cartridge. Alpha-cypermethrin residues are determined by packed column GC (GE-XE 60 1.2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD); quantification by external standardization. Residues of alpha-cypermethrin are confirmed by capillary GC-ECD (SE-54; 0.5 μ m) for resolution of the Cis-1, Trans-3 and Trans-4 isomers from alphacypermethrin (Cis-2) and GC-MS (CP SIL 5 CB), MS operated in negative ion chemical ionisation mode (ions monitored : m/e 207 and 209).

Specificity/Interference	Typical packed column GC-ECD chromatograms are shown; control samples exhibit no significant interfering peaks at the retention time of alpha-cypermethrin.
Recovery/Precision	see Table **4.1.2-55**
Limit of Quantification	0.1 mg/kg

Table 4.1.2-55: Validation of method SAMS 461-01 (no author specified, 1988)

Matrix	Analyte	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
fat	alpha-cypermethrin	0.1 0.2	6 2	80 - 100 100 - 115	94.2 107.5	8.5 (9.9)
		0.1 - 0.2	8	80 - 115	97.5	10.3
muscle	alpha-cypermethrin	0.1 0.2	3 1	85 - 100 90	90 -	9.6 -
		0.1 - 0.2	4	85 - 100	90	7.9
kidney	alpha-cypermethrin	0.1 0.2	2 1	85 - 95 90	90 -	(7.9) -
		0.1 - 0.2	3	85 - 95	90	5.6
liver	alpha-cypermethrin	0.1 0.2	2 1	80 - 95 95	87.5 -	(2.1) -
		0.1 - 0.2	3	80 - 95	90	9.6
overall	alpha-cypermethrin	0.1 0.2	13 5	80 - 100 90 - 115	91.5 98	8.5 10.6
		0.1 - 0.2	18	80 - 115	93.3	9.4

Conclusion **In terms of interfering blanks, accuracy (mean recoveries between 70 and 110%) and precision (RSD's lower than 20%), the method is suitable for alpha-cypermethrin residue analysis in animal tissues with a LOQ of 0.1 mg/kg.**

Report:	CA 4.1.2/50 Anonymous, 1988 Determination of residues of Alphacypermethrin in milk - Gas liquid chromatographic method
	AL-245-003
Guidelines:	not stated
GLP:	not stated

Principle of the method :
Milk samples are extracted by shaking with aqueous potassium oxalate solution, ethanol, diethyl ether and hexane. The extract is evaporated to dryness and the residue is redissolved in hexane, after which partition between acetonitrile and hexane is achieved rapidly by means of an Extrelut extraction column. Further clean-up is obtained by use of a cyano Bond Elut cartridge.
Alpha-cypermethrin is determined by packed column GC (GE-XE 60 1.2% (m/m) on Gas Chrom Q (100-120 mesh)) with electron capture detection (ECD); quantification by external standardization. Residues of alpha- cypermethrin are confirmed by capillary GC-ECD (SE-54; 0.5 µm) for resolution of the Cis-1, Trans-3 and Trans- 4 isomers from alphacypermethrin (Cis-2) and GC-MS (CP SIL 5 CB), MS operated in negative ion chemical ionisation mode (ions monitored : m/e 207 and 209).

Specificity/Interference	Typical packed column GC-ECD chromatograms are shown; control sample exhibits no significant interfering peaks at the retention time of alpha-cypermethrin.
Recovery/Precision	see Table **4.1.2-56**
Limit of Quantification	0.005 mg/L

Table 4.1.2-56: Validation of method SAMS 456-01 (no author specified, 1988)

Matrix	Analyte	Fortification level (mg/L commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
milk	alpha-cypermethrin	0.005 0.010 0.015 0.020	1 2 1 1	105 95 - 105 100 90	- 100 - -	- (7.1) - -
		0.005-0.020		90-105	99	6.6

Conclusion	**In terms of interfering blanks, accuracy (overall mean recovery between 70 and 110%) and of precision (overall RSD lower than 2 %), the method is suitable for residue analysis in milk.**

Report:	CA 4.1.2/51 Doran A.M., Mayer I. H., Khunachak A., 1999 Renegade Alphacypermethrin (CL 900049): Validation of analytical methods SAMS 461-1 and SAMS 456-1 for the determination of Alphacypermethrin residues in cattle tissues (muscle, fat, kidney and liver) and milk
	AL-245-006
Guidelines:	The Rules Governing Medicinal Products in the European Community - Volume VI
GLP:	Yes (Department of Health of the Government of the United Kingdom)

Remark: Study AL-245-006 is part of residue study RES 01-008.

Principle of the method:
The purpose of the study was to further validate methods SAMS 461-1 and SAMS 456-1. Method SAMS 461-1 for analysis of tissue samples and method SAMS 456-1 for analysis of milk samples are described in the draft monograph; deviations from these methods were minor. Quantification of the residues by both methods is achieved by capillary GC (SE 54; 15 m x 0.32 mm i.d.; 0.25 µm) with ECD. Confirmation by GC/MS, MS operated in CI-(methane) ionization mode (ions monitored: 207 and 209 amu). External calibration was used for purpose of quantification

Specificity/Interference	Specificity was demonstrated. Untreated control samples exhibit no significant interferences; representative chromatograms are shown.
Linearity:	The response of the GC-ECD system (= peak area) to alpha-cypermethrin was demonstrated to be linear over a range from 0.01 to 0.10 µ g (n = 4, single injection). The linear curve was provided in the study report with a correlation coefficient > 0.9997. Calibration seems to have been performed in solvent but this is not clearly mentioned in the study report. Matrix effects were not assessed. The extensive sample clean-up (liquid/liquid partitioning and/or SPE) removes the naturally occurring matrix effects.
Recovery/Precision	see Table **4.1.2-57**

Table 4.1.2-57: Validation of methods SAMS 461-1 and SAMS 456-1 (Doran, Mayer & Khunachak, 1999)

Matrix	Analyte (fortification)	Fortification level (mg/kg commodity)	Recovery

Additional data from study RES 01-008:

Table 4.1.2-58: Procedural recoveries as reported in study RES 01-008

Matrix	analyte	Fortification range	Recovery %	Average recovery %
Muscle	Alpha-cypermehtrin	50-500 ppb (0.05 – 0.5 mg/kg)	65-102	85 (n=4, 2 at each level))
Fat	Alpha-cypermehtrin	50-500 ppb (0.05 – 0.5 mg/kg)	92-112	102 (n=4, 2 at each level)
Kidney	Alpha-cypermehtrin	50-500 ppb (0.05 – 0.5 mg/kg)	75-102	90 (n=4, 2 at each level)
Liver	Alpha-cypermehtrin	50-500 ppb (0.05 – 0.5 mg/kg)	82-104	92 (n=4, 2 at each level)
milk	Alpha-cypermehtrin	10-100 ppb (0.01 – 0.1 mg/L)	75-106	92 (n=4, 2 at each level)
Muscle	Alpha-cypermehtrin	50-500 ppb (0.05 – 0.5 mg/kg)	89-99	94 (n=2)
Fat	Alpha-cypermehtrin	50-1200 ppb (0.05 – 1.2 mg/kg)	76-117	97 +/- 19 (n=4)
Kidney	Alpha-cypermehtrin	50 ppb (0.05 mg/kg)	92-93	93 (n=2)
Liver	Alpha-cypermehtrin	50-500 ppb (0.05 – 0.5 mg/kg)	88-90	89 (n=2)
milk	Alpha-cypermehtrin	10-100 ppb (0.01 – 0.1 mg/L)	77-119	95 +/- 13 (n=30)

It should also be noted that a validation study performed by [redacted] was also presented and part of the study report RES 00-052: *CL 900049 (alpha-cypermethrin): Validation of SAMS Method 461-1 and Magnitude of the Residue of CL 900049 in Laying hen Tissues (meat, Liver and Abdominal Fat) – Analytical Phase Report –* [redacted] *2001, Study No. A054.010, GLP, Unpublished.* Minor modifications to the initial method were reported including slight amendment of the GC conditions (DB-5, 15 m× 0.53 mm, 1.5 µm). The extraction method remained unchanged.

The findings for the validation were as followed:

Specificity/Interference No significant interference has been observed at the retention time of alphacypermethrin. Chromatograms were provided for a standard solution, controls, fortified samples at LOQ and 10×LOQ and treated samples. GC-ECD is not a specific method. No information is provided about confirmation in that study report but GC-MS can be used as previously described.

Linearity: Method was found to be linear in the 0.0015 – 0.015 µg/mL range with a correlation coefficient of 0.9992 (n=5). The calibration curve and the regression equation were provided. Calibration in solvent was used for quantification.

Recovery/Precision: The method was validated at two fortification levels (0.05 and 0.5 mg/kg) in hen eggs. For each fortification level, five replicates were analyzed. Additionally, two replicates of unfortified samples were examined. Results are presented in table below.

Table 4.1.2-59: Validation of method SAMS 461-1 for determination of alpha-cypermethrin in laying hen tissues (Meat, Liver and Abdominal Fat)

Matrix	Analyte (fortification)	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
Method SAMS 461-1						
Meat	α-cypermethrin	0.05	5	95-115	104	7.9
		0.50	5	74-102	84	16.2
		Overall	10	74-115	94	
Liver	α-cypermethrin	0.05	5	79-87	83	3.5
		0.5	5	74-89	82	6.7
		Overall	10	74-89	83	
Fat	α-cypermethrin	0.05	5	86-109	102	7.6
		0.5	5	93-108	98	6.3
		Overall	10	89-109	100	

Remark: Recoveries run concurrently with samples showed also acceptable recoveries:
- Meat at 0.05 mg/kg: 115% (n=1)
- Liver at 0.05 – 0.5 mg/kg: 78 and 88 % (n=1 each)
- Fat at 0.05 mg/kg: 87 and 107% (n=2) and at 0.5 mg/kg: 86% (n=1).

Limit of Quantification	0.05 mg/kg for each matrix.
Conclusion:	**Methods SAMS 461-1 and 456-1 have been used in support of feeding studies in poultry and ruminants and the results of these studies can be considered reliable.**

Report:	CA 4.1.2/52 Hausmann S., 2000 Alphacypermethrin (CL 900049): Validation of the multi-residue method DFG S19 with modified extraction for the determination of Alphacypermethrin residues in milk and eggs AL-245-007
Guidelines:	EEC 91/414 Annex II 4.2.1, EU Guideline 8064/VI/97 rev. 4 15.12.1998
GLP:	Yes (Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz, Germany)

Principle of the method:
Water is added to the samples in an amount that takes the natural water content of the samples into account so that during extraction, the water/acetone ratio remains constant (1/2 v/v). Thus water/acetone (1/2 v/v, 300 mL) is used for extraction followed by partition in acetone/ethyl acetate/cyclohexane (which replaced dichloromethane). GPC is used for elimination of fat and macro-molecules. Adsorption chromatography on silica gel with precisely defined fractionation (the silica gel cleanup is performed according to DFG S19 with some modifications). The analysis is performed by GC-ECD (non-polar 5% phenyl methyl silicone fused silica capillary column, stationary phase, 30 m × 0.25 mm, 0.25 µm film thickness, oven: 100°C hold 2 min., rate 25°C/min. to 260°C hold 4 min., rate 25°C/min to 280°C hold 6 min (milk) and 10 min (eggs)). External calibration. GC/MS was used as a confirmation method (using a 5 % phenyl methyl siloxane fused silica capillary column, non polar stationary phase: 30 m × 0.25 mm, 0.25 µm film thickness, SIM : m/z 181, 163 and 165 for monitoring and identification and m/z 181 taken for quantification). GC-NPD was also demonstrated as an alternative method for determination of alpha-cypermethrin in milk and eggs (5 % phenyl methyl silicone fused silica capillary column, 30 m × 0.25 mm, 0.25 µm film thickness, oven: 70°C hold 1.3 min, rate 25°C/min to 280°C hold 10 min), detection at 320°C).

Specificity/Interference	No interference has been observed at the retention time of alphacypermethrin. GC-ECD Chromatograms were provided for standard solutions, controls, fortified samples at LOQ and 10×LOQ, GC-MS chromatograms were provided for calibrations, controls and fortified samples at LOQ and GC-NPD chromatograms were provided for a calibration and fortified samples. Confirmation of the GC-ECD occurred by GC-MS monitoring three m/z ions 181, 163 and 165, with m/z 181 used for quantification.
Linearity:	The response of the detector was found quadratic in the 0.02 – 1.0 µg/mL range (n = 6, single injection) for the GC-ECD (eggs), for the GC-MS (for milk and eggs) and linear in the same concentration range for the GC-ECD (in milk). It was not clearly stated if the calibration occurred with matrix-matched standards. Two calibration curves were provided (one quadratic and one linear) both with a r2 > 0.99 (0.9988 for milk by GC-ECD and 0.99959 for milk and eggs by GC-MS).
Recovery/Precision:	Milk and egg samples have been fortified with alpha-cypermethrin at two levels (0.01 mg/kg and 0.1 mg/kg).

Table 4.1.2-60: Validation of method DFG S19 for the determination of alpha-cypermethrin in milk and eggs

Matrix	Analyte (fortification)	Fortification level (mg/kg commodity)	Recovery		
			Number of samples Range (%)	Mean (%)	RSD (%)
milk	α-cypermethrin	0.01 0.1	5 5	93 100	9 6
		0.01 (confirmation by GC-MS)	1	78	-
		0.1 (confirmation by GC-MS)	1	104	-
eggs	α-cypermethrin	0.01 0.1	5 5	97 79	3 3
		0.01 (confirmation by GC-MS)	1	103	-
		0.1 (confirmation by GC-MS)	1	96	-

Limit of Quantification 0.01 mg/kg

Conclusion: The method is considered sufficiently validated in regards of SANCO/3029/99 rev. 4. The method allows the determination of alpha-cypermethrin in milk and egg samples with a validated LOQ of 0.01 mg/kg in each matrix. However the method is not used in support of residue studies considered for the purpose of the renewal.

Report:	CA 4.1.2/53 Walker B., Linkerhägner M., 2000 Alphacypermethrin (AC 900049): Validation of the DFG method S 19 (extended revision) for the determination of residues of Alphacypermethrin in blood and urine of animal origin (swine) AL-245-008
Guidelines:	EEC 91/414, EEC 96/46 4.2.1, SANCO/825/00 rev. 6 (20 June 2000),BBA Guideline Residue Analytical Methods for Post-Registration Control Purposes of July 21 1998,EPA 860.1340
GLP:	Yes (Behoerde fuer Arbeit, Gesundheit du Soziales, Frei und Hansestadt, Hamburg, Germany)

Principle of the method

The extraction of alpha-cypermethrin from swine blood and urine was performed according to extraction module E1 (DFG method S19): specimen material is extracted with acetone. Water is added beforehand in an amount that takes full account of the natural water content of the specimen so that during extraction the acetone/water ratio remains constant at 2:1 (v/v). For liquid/liquid partition ethyl acetate/cyclohexane (1:1) and sodium chloride are added and after repeated mixing excess water is separated. The evaporated residue of the organic phase is cleaned up by gel permeation chromatography (GPC) and silica gel column chromatography (module C1) according to DFG method S19 (extended revision). All specimens are analyzed by capillary gas chromatography with electron capture detection (GC-ECD) on a fused silica capillary column (DB1; J&W) with argon/methane (95:5) as carrier gas at a flow rate of 1.0mL/min.

Recovery findings

Average recoveries for all fortification levels were between 70 and 110%. Average recoveries for each matrix are summarized in Table **4.1.2-61**.

Table 4.1.2-61: Results of method validation: BAS 310 I (alpha-cypermethrin) in swine blood and urine specimens

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Blood	BAS 310 I	0.005	5	105	4.3	4.1
		0.05	5	101	3.4	3.4
Urine	BAS 310 I	0.005	5	96	6.0	6.3
		0.05	5	95	2.7	2.8

Linearity	Linearity was tested using six calibration standards in the range of 0.00250-0.0998 µg/mL, covering the working range, with a correlation coefficient >0.99. Standards were prepared in toluene.
Specificity	A confirmatory method has not been performed; however, no significant interferences of matrix or labware have been reported. Control specimens yielded no residues above the limit of detection (0.001 mg/kg), i.e.<30% LOQ. Good validation results have been achieved with the primary method.
Limit of Quantification	The limit of quantification (LOQ) for BAS 310 I is 0.005 mg/kg for blood and urine.
Repeatability	The relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table **4.1.2-61**.
Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.
Standard stability	Stability of standards was not determined within this validation study.
Conclusion	**The method DFG S19 is considered sufficiently validated for the determination of residues of alpha-cypermethrin in blood and urine.**

Guidelines:	Guidance Document on Residue Analytical Methods (SANCO/825/00rev.6 EPA 860.1480, EEC 91/414,EEC 7031/VI/95 Appendix G rev. 4,SANCO/3029/99 rev. 4 (11 July 2000),8046/VI/97-rev 4 (15/12/1998))
GLP:	Not stated

Principle of the method:

Residue of alpha-cypermethrin are extracted from homogenized samples of eggs with a mixture of hexane and tetrahydrofuran (THF) 1:2 v:v. Aliquots of the organic extract are evaporated and the residue is dissolved in a mixture of hexane and dichloromethane 1:1 v:v. Extracts are purified using adsorption chromatography on a one gram Silica SPE cartridge, followed by liquid/liquid partitioning using hexane/acetonitrile. Quantitative determination is carried out by gas chromatography/Electron Capture Negative Ion Chemical Ionization Tandem Residue of alpha-cypermethrin are extracted from homogenized samples of eggs with a mixture of hexane and tetrahydrofuran (THF) 1:2 v:v. Aliquots of the organic extract are evaporated and the residue is dissolved in a mixture of hexane and dichloromethane 1:1 v:v. Extracts are purified using adsorption chromatography on a one gram Silica SPE cartridge, followed by liquid/liquid partitioning using hexane/acetonitrile. Quantitative determination is carried out by gas chromatography/Electron Capture Negative Ion Chemical Ionization Tandem.

Specificity/Interference	No significant interference has been observed at the retention time of alphacypermethrin. Chromatograms were provided for a standard solution, control, fortified samples at LOQ and 10×LOQ and treated samples. Method is specific by monitoring several m/z ions. However, only one ion fragment (m/z: 207) was considered here for quantification.
Linearity:	Method was found to be linear in the 0.0025 – 0.030 µg/mL range with a correlation coefficient of 0.9997 (n=5). The calibration curve and the regression equation were provided. However, it is not indicated in the study report if the calibration was performed with matrix-matched standard solutions or with calibration standards in solvent. The presence or absence of matrix effect was not reported. However, the extensive sample clean-up (liquid/liquid partitioning and/or SPE) would remove the naturally occurring matrix effects.

Recovery/Precision The method was validated at two fortification levels (0.01 and 0.1 mg/kg) in hen eggs. For each fortification level, five replicates were analyzed. Additionally, two replicates of unfortified samples were examined. Results are presented in Table **4.1.2-62**.

Limit of Quantification: 0.01 mg/kg.

Table 4.1.2-62: Validation of method M3466 for determination of alpha-cypermethrin in hen eggs

Matrix	Analyte (fortification)	Fortification level (mg/kg commodity)	Recovery			
			Number of samples	Range (%)	Mean (%)	RSD (%)
Method M3466						
Hen egg	α-cypermethrin	0.01 0.10	5 5	102 – 119 79 – 98	110 92	7 11
Blood	α-cypermethrin	0.005	3	Retention times: ≤0.1% difference from bracketing standards Ion ratios: ≤5.5% difference compared to the standards		

Stability: Residue sin extracts are shown to be stable for 7 days.

Conclusion: **Method M3466 is validated according to SANCO/3029/99 rev. 4. The method is suitable for the quantification of alpha-cypermethrin and is suitable to support the feeding study in poultry. The results obtained can be considered reliable.**

(f)Methods in soil, water, sediment, feed and any additional matrices used in support of ecotoxicology studies

No stand-alone analytical methods were validated in support of ecotoxicological studies. Methods for the determination of concentration, whenever necessary, are reported along with the respective ecotoxicological study.

No stand-alone analytical methods were validated in support of ecotoxicological studies. Methods for the determination of concentration, whenever necessary, are reported along with the respective ecotoxicological study as well as summarised below. Validation parameters are summarised under the DocID of the ecotoxicological studies as analytical phase reports have not been issued. In such cases where a method was used for a large number of studies, validity criteria are addressed in overview tables to facilitate review.

Report:	CA 4.1.2/55 [redacted] 2009 BAS 310 I – Acute toxicity in the zebra finch (Taniopygia guttata) after single oral administration (LD50)
	2009/1114317
Guidelines:	EPA 540/9-82-024, EPA 540/9-85-007,EPA 850.2100,EPA 712-C-96-139,EPA 71-1
GLP:	Yes (Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method:
Samples were transferred with approximately 100 mL acetonitrile/highly deionized water 1/1 (v/v) into 500 mL measuring flasks and were made up to the calibration marc with acetonitrile and dissolved under sonication. Aliquots of the dilutions were used for HPLC-UV analysis (column: Synergy Fusion RP 80 4 µm, 250 m x 3 mm, eluent 80% acetonitrile + formic acid (1,000 + 1 mL)/15 % highly deionized water + formic acid (1,000 + 1 mL, detection at 198 nm). External calibration. Matrix analysed was 0.5 % carboxymethylcellulose (CMC) in drinking water.

Dose verification and stability for 6h at room temperature were verified.

Specificity/Interferences:	No interferences occurred at the retention time of the analyte in the control sample (0.5 % CMC in drinking water). Chromatograms were provided for standard solutions, blank and samples. The identity was confirmed on the basis of the selected wavelength and the retention time. The method is used for dose verification of known substances and known nominal concentrations. Hence, no additional confirmatory technique is necessary.
Linearity:	Method was found to be linear: in the ~ 8.112 – 50.7 mg/100mL range (3 different concentrations, duplicate infection). Calibration in acetonitrile/highly deionized water 1/1 v/v, further diluted with acetonitrile. The calibration curve was provided but not the regression equation and the correlation coefficient. However, since the calibration curve showed good linearity, no further data are required. The concentration of the samples meet the calibration range.
Limit of Quantification:	8.112 mg/100 mL (0.08112 mg/mL) corresponding to 4.056 % w/w (lowest calibration concentration).

Table 4.1.2-63: Dose verification and stability data for alpha-cypermethrin in 0.5% CMC in drinking Water

Sample matrix/analyte	Nominal concentration % w/w (corresponding concentration in mg/100 mL)	Nominal concentration in mg/kg bdw	% of the nominal concentration	n*
Dose verification				
0.5% CMC in drinking water/alpha-cypermehtrin	5 (10 mg/100 mL)	500	102.1	1 × 2
	10 (20 mg/100 mL)	1000	101.3	1 × 2
	20 (40 mg/100 mL)	2000	100.2	1 × 2
Stability				
0.5% CMC in drinking water/alpha-cypermethrin	1.092 (0h) (~ 2 mg/100 mL)	-	99.5	1 × 2
	1.060 (6h) (~ 2 mg/100 mL)	-	95.4	1 × 2

Note: for the stability determination, a separate analytical report was done and was part of the study KCA 8.1.1.1/001. In that analytical report, a new calibration curve was performed and chromatograms were also provided.
* one replicate at each level with duplicate injections.

Conclusion: The method is suitable for the determination of alpha-cypermethrin in 0.5% CMC in drinking water used in gavage studies on birds. The method has been used in study KCP 10.1.1.2/001. The LOQ and the validated working range meet the ecotox endpoint.

Principle of the method APL0445/01:

Method applied here was method APL0445/01 developed for analysis of alpha-cypermethrin in soil, water and blood and validated under study 130428 (method validation M3499-01 – Xu B. 2001 - BAS 310 I (alpha- cypermethrin): GC-MS confirmatory method for BAS 310 I residues in water, soil and blood). Samples were extracted by solvent partition with hexane and diluted to be within the calibration range with hexane after evaporation to dryness. To improve the performance of the method, n-heptane was used. Therefore, trace amounts of alpha- cypermethrin dissolved or suspended in water were enriched by liquid/liquid extraction with n- heptane, the organic layers were combined and evaporated to dryness using a rotary evaporator under vacuum. The residue was then re-dissolved in L-gluconic acid-Lactone 1 mg/mL in acetone in an appropriate range for analysis. Analysis occurred by GC-MS (DB-5 column, 30 mm x 0.32 mm i.d, 0.25 µm particle size; ion monitored: m/z = 207). External calibration was used for quantification purposes.

Validation was not done for each available water type. If the method is shown to be suitable for quantification purposes in the most difficult water matrix, e.g. in terms of salt or matrix load, the easier matrices were not fully validated again, as the matrix is mainly water.

Table 4.1.2-64: Validation data for method L0045/01 (M3499) to determine alpha-cypermethrin in water

Study/ Matrix and Analyte	LOQ (µg/L)	Linearity* Range (µg/L) (n) Correlation coefficient r	Fortification levels	Specificity and interferences
CA 4.1.2/56 2009/1031203 Drinking water/alpha-cypermethrin	0.02	0.02 – 5 (n=5, duplicate injection) r ≥ 0.999 Calibration curve and regression equation provided	Samples of nominal concentrations between 0.019 and 1.2 µ g/L were prepared, analysed directly and after 7 days storage at room temperature and deep frozen. Mean recovery at each fortification level remains within the 70-110% range. Analysis of retained samples (stored for 7 days at room temperature or deep frozen) showed some losses in concentration.	Blank control was not tested during the fortification experiment but blank controls during the ecotoxicity study showed no significant interferences occurring at the retention time of alpha-cypermethrin except in one sample for which contaminations during sample preparation were suspected. Some typical chromatograms were provided for a blank control, a standard, a sample at 0.15 µ g/L at day 0 and day 4, stock solution at 1.4 µ g/L. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
CA 4.1.2/57 2007/1016502 Reconstituted water (M4 medium)/alpha-cypermethrin	0.01	3.2 – 26 (n=4, duplicate injection) $r^2 \geq 0.999$ Calibration curve and regression equation provided	Fortified samples were prepared at levels in the range of the test samples and atlevel of the stock solution. Mean recovery at each level is presented in the table below.	No significant interference from the blank control was stated in the study report. Chromatograms were provided for the blank solution (M4 medium), standard solutions and test sample at 37.2 ng/L at initiation of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
CA 4.1.2/58 2009/1109081 Algal medium (OECD medium according to OECD guideline 201 /alpha-cypermethrin	2.0	0.05 – 5 (n=4, duplicate injection) $r^2 \geq 0.998$ Calibration curve and regression equation provided. The concentration of the samples meet the calibration range, otherwise dilution occurred to meet the calibration range	2– 50 Mean recovery at each level is presented in the table below.Two controls were tested concurrently with the test. Degradation of test item occurred below the LOQ after 4 days at room temperature.	No significant interference from the blank control was stated in the study report. Chromatograms were provided for the blank solution (OECD medium), a standard solution and test samples at initiation and end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard

CA 4.1.2/59 2009/1109080 Algal medium (1×APP medium)/alpha-cypermethrin	2.0	0.05 – 5 (n=4, duplicate injection) $r^2 \geq 0.999$ Calibration curve and regression equation provided. The concentration of the samples meet the calibration range, otherwise dilution occurred to meet the calibration range	2– 50 Mean recovery at each level is presented in the table below. Two controls were tested concurrently with the test. Degradation of test item occurred below the LOQ after 4 days at room temperature.	No significant interference from the blank control was observed. Chromatograms were provided for the blank solution (algal medium), a standard solution and test samples at initiation and end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
CA 4.1.2/60 2009/1109079 Algal medium (ESW medium)/alpha-cypermethrin	2.0	0.05 – 5 (n=4, duplicate injection) $r^2 \geq 0.999$ Calibration curve and regression equation provided. The concentration of the samples meet the calibration range, otherwise dilution occurred to meet the calibration range.	2– 50 Mean recovery at each level is presented in the table below. Two controls were tested concurrently with the test. Degradation of test item occurred below the LOQ after 4 days at room temperature.	No significant interference from the blank control was observed. Chromatograms were provided for the blank solution (algal medium), a standard solution and test samples at initiation and end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the Standard.
CA 4.1.2/61 2009/1108874 20×APP medium/alpha-cypermethrin	2.0	0.06 – 6 (n=4, duplicate injection) $r^2 \geq 0.999$ Calibration curve and regression equation provided. The concentration of the samples meet the calibration range, otherwise dilution occurred to meet the calibration range.	2– 120 Mean recovery at each level is presented in the table below. Two controls were tested concurrently with the test. Stability test in the carrier for 120 µ g/L sample showed slightly degradation of the test item after 7 days	No significant interference from the blank control was observed. Chromatograms were provided for the blank solution (algal medium), a standard solution and test samples at initiation and end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard
CA 4.1.2/62 2009/1011443 OECD algal medium according to OECD guideline 201 / alpha-cypermethrin	0.029 mg/L BAS 310 51I. However, based on the data reported, it appears that it should be 0.025 mg/L BAS 310 51 I	5 – 100 for BAS 310 51 I (5 concentrations, duplicate injection), corresponding to $r^2 \geq 0.998$ Calibration curve and regression equation provided. The concentration of the samples meet the calibration range, otherwise dilution occurred to meet the calibration range.	25-93000 for BAS 310 55 I corresponding to ~ 1.2 µ g a.s./L and 4600 µ g a.s./L, respectively. Two controls were tested concurrently with the test. After three days (room temperature), slightly degradation was observed.	No significant interference from the blank control was observed. Chromatograms were provided for the blank solution (algal medium), a standard solution and test samples at initiation and end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard

Table 4.1.2-65: Mean recoveries and RSD obtained for method L0045/01 for the determination of alpha-cypermethrin in water

Matrix/analyte	Fortification levels (µg/L)	Mean recovery % (range)	RSD %	n
CA 4.1.2/56 2009/1031203 Drinking water/alpha-cypermethrin	0.019 (directly measured at day 0)	100.7	-	1×2**
	0.296 (directly measured at day 0)	98.5	-	1×2**

	4.61 µ g/L	115.5	-	2×2
	Day 14 at concentration representative for the stock solution			
	5.48 µ g/L	105.2	-	2×2
	Day 17 and 19 at concentration representative for the stock solution			
	4.87 µ g/L	71.9	-	2×2

* recoveries found during the test (test samples) were all within the 70-110% range except for the 37.2 ng/L after day 0 and day 7 (recovery > 110%), for the 74.4 ng/L level for day 7 (recovery > 110%), for stock solutions at 5 µg/L at day 0 and day 7 (recovery < 70%).
** n = 2 corresponds to two replicates, each injected two times.

Limit of Quantification: The proposed limit of quantification is 0.0287 µg/L which was confirmed by n=4 fortification samples in M4-enriched medium. 0.019 µg/L are achievable, but this has been confirmed by n=2 replicates only.

Conclusion: **The method is considered suitable for the quantification of alpha-cypermethrin in various aqueous media using GC-ECD.**

Report:	CA 4.1.2/63 Janson G.-M.,Weltje L., 2009 Acute toxicity of BAS 310 I (Reg.No. 4078193) to larvae of the phantom midge Chaoborus crystallinus in a 48 hour static test 2009/1085205
Guidelines:	OECD 202, SANCO 3029/99 rev.4
GLP:	Yes (Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: the report on the analytical phase written by Class T. 2009 was part of the Study by Janson G-M. and Weltje L. 2009.

Principle of the method APL0445/01:

Water samples were extracted in centrifuge vials or separatory funnels 3-times after adding 3 mL of a saturated sodium chloride solution by liquid/liquid partition with n-hexane (each time 3 mL). After phases separation aided by centrifugation (5 min., 3000 rpm), the combined organic phases were concentrated to near dryness adding about 1 mL of toluene as keeper. The final extract volume was then adjusted to 0.25, 0.5, 1 or 2 mL for GC-ECD injection (Varian VF-1701 MS fused silica capillary column, 30 mm x 0.32 mm i.d, 0.25 µm particle size; oven program: 90°C, 2.0 min. hold, ramp 30°C/min to 300°C, 4 min. hold at 300°C). External calibration. The column used is able to distinguish the isomers of cypermethrin.
Matrix: Mesocosm water. Characteristics of the water: 2.23 mmol/L total hardness, 2.2 mmol/L alkalinity up to pH 4.3, pH = 7.97, conductivity of 552 µS/cm. For validation tap water from the laboratory.

Specificity/Interference	No interferences occurred at the retention time of alpha-cypermethrin. Chromatograms were provided for calibration solutions, tap water as blank control, test samples, BASF pond water, BASF water blank control, solvent control and fortified samples at 5 ng/L. Identification was performed by comparison of the retention time in the test sample with the standard .
Linearity:	Method was found to be linear : $r^2 \geq 0.999$ in the 0.25 – 25.0 ng/mL range (7 concentrations, duplicate injection). Calibration occurred in toluene. The water was extracted by liquid-liquid partitioning using n-hexane. Analysis of the respective untreated water samples confirm the absence of any interference; additionally, due to the partitioning, naturally occurring interferences would have been removed. The corresponding linear regression plot and equation were provided. The prepared samples meet the calibration range.
Accuracy:	Samples of water were fortified at different concentration levels. Mean recoveries are provided in the table below.
Repeatability:	Relevant RSDs are reported in the table below.
Limit of Quantification:	5 ng/L

Table 4.1.2-67: Alpha-cypermehtrin validation results from water in a mesocosm study

Sample matrix/analyte	Fortification level (ng/L)	Alpha-cypermehtrin recovery (%) Mean (range)		RSD (%)	n
Tap water/alpha-cypermethrin	5	110 (100-117)*		7	6
	5000	98 (95-101)		-	2
	1250	89		-	1
	470	80		-	1
Tap water data overall		**Range: 80 – 117**	**102**	**12**	**10**

* Three from the individual recoveries were equal to 117% (> 110%).

Conclusion: **The method is considered fit for purpose to support the data generated. The propose LOQ is considered validated and covers the relevant ecotoxicological endpoints.**

Report:	CA 4.1.2/64 Janson G.-M., Dorner S., Weltje L., 2009 Acute toxicity of Alpha-Cypermethrin (BAS 310 I) and of Cypermethrin (BAS 311 I) to the non-biting midge Chironomus riparius in a 48 hour static test 2009/1102214
Guidelines:	OECD 202
GLP:	Yes (Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method:

Ecotox water samples were extracted in separatory funnels 3-times with n-hexane. The combined organic extract was transferred into a tapered 25-mL or 50-mL flask, concentrated using a rotary evaporator to near dryness using a gentle stream of nitrogen. The final extract volume was then adjusted to 0.25 or 0.2 mL with 10-ng/mL IS solution (vortex and sonicate) for GC/ECD injection (Varian VF-1701 MS fused silica capillary column 30 m ×0.32 mm, 0.25 µm, internal calibration using lambda-cyhalothrin). The column used is able to distinguish the isomers of cypermethrin. Matrix**:** reconstituted water (M4 medium according to Elendt: prepared on the basis of ultrapure deionized water and containing Tween 80 at 2 µ/L), characteristics: 2.45 mmol/L total hardness, 0.88 mmol/L alkalinity up to pH 4.3, 7.99 pH, 665 µs/cm conductivity. Fortification were performed on tap water.

Specificity/Interference	No significant interference from the blank controls was stated in the study report. Chromatograms were provided for the blank solution (tap water but not for the blank of the test: M4 medium / Tween 80), standard solutions, fortified samples at LOQ and 100 ng/L and test samples for both analytes. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
Linearity:	Method was found to be linear: $r^2 \geq 0.998$ in the 0.5 – 50.0 ng/mL (n = 5) for alpha-cypermethrin and $r^2 \geq 0.998$ in the 0.5 – 100.0 ng/mL (n = 6) for cypermethrin. Calibrations were prepared in toluene. The water/control media were extracted by liquid-liquid partitioning using n-hexane. Analysis of respective untreated water samples confirm the absence of any interference; additionally, due to the portioning, naturally occurring interference would have been removed. The corresponding linear regression plots and equations were provided.
Accuracy:	Samples of tap water were fortified with 5 and 100 ng/L of each of the analyte. Mean recovery at each fortification level and for each analyte is presented in the Table below.
Repeatability:	RSD was reported in table below and is lower than 20%.
Limit of Quantification:	5 ng/L

Table 4.1.2-68: Alpha-cypermethrin validation results from water

Sample matrix/analyte	Fortification level (ng/L)	Alpha-cypermehtrin recovery (%) Mean (range)	RSD (%)	n
Tap water/alpha-cypermethrin	5	106 (102-109)	4	3
	100	99 (98-99)	1	3
	5	103 (95-109)	6	6
	100	82 (70-92)	11	3

Conclusion: **The method using a capillary column allows the distinction of the four isomers of cypermethrin and the method is also considered as validated with an LOQ of 5 ng/L for cypermethrin (sum of all isomers). For the GC-ECD method (LOQ = 5 ng/L and validated working range of 5 – 500 ng/L), the LOQ covers the endpoints and the validated working range covers the mean measured concentrations except the lowest level but this level (4 ng/L) is very close to 5 ng/L. Therefore, the method is considered sufficiently "fit for purpose" and the ecotox results are therefore considered as reliable.**

Report:	CA 4.1.2/65 Backfisch K.,Weltje L., 2011 Chronic toxicity of Reg.No. 4078193 (BAS 310 I; Alpha-Cypermethrin) to the non-biting midge Chironomus riparius - A spiked sediment study 2011/1124187
Guidelines:	OECD 218 (2004)
GLP:	Yes (Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method:

Alpha-cypermethrin was determined in the water samples (overlaying water and sediment pore water samples) by liquid/liquid partition into hexane and GC/ECD determination based on internal calibration (same method as described in KCA 8.2.5.3/001). Alpha-cypermethrin was determined in the sediment samples by modified DFG S19 method and GC/MS (Varian VF-5 MS, 30 m × 0.32 mm, 0.25 µm or Machery-Nagel OPTIMA – 17 ms, 30 m × 0.32 mm, 0.25 µm, monitored ion: m/z 207) based on internal calibration (lambda cyhalothrin). At 2.5 g of a homogenized specimen, 10 mL of water was added and let the sample soak for 10 min. 40 mL of acetone were added and the mixture shaken for 30 min. with the horizontal shaker. 7.0 g of sodium chloride were added to the homogenate and 20 mL of GPC eluting mixture (ethyl acetate/cyclohexane 1/1 v/v). The sample was shaken for 30 min. When the phases were clearly separated, an aliquot of 6.0 mL of the upper organic phase was taken and evaporated to dryness using constant stream of nitrogen. The final volume was then adjusted to 0.2 mL or 1.0 mL (for higher fortification level) with 10 ng/mL IS solution (vortex and sonicate) for GC-MS injection.

Matrix:

- reconstituted water (M4 medium according to Elendt: prepared on the basis of ultrapure deionized water), characteristics: 2.53 mmol/L total hardness, 0.9 mmol/L alkalinity up to pH 4.3, 7.94 pH, 678 µs/cm conductivity. Fortification were performed on tap water or M4 medium.
- Sediment: artificial substrate as described in OECD guideline 218 (2004).

Specificity/Interference	No significant interference from the blank controls (M4 water, tap water, sediment, solvent) was observed. Chromatograms were provided for the blank solution (tap water, M4 water, sediment), standard solutions, internal standard, fortified samples at LOQ and higher fortification levels and test samples at the initiation and at the end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
Linearity:	For water: Method was found to be linear: $r^2 \geq 0.999$ in the 0.5 – 50.0 ng/mL (n = 7) for alpha-cypermethrin. Calibrations were prepared in toluene. The corresponding linear regression plots and equations were provided. For sediment: Method was found to be linear: $r^2 \geq 0.999$ in the 0.25 – 50.0 or 100 ng/mL (n ≥ 7) for alpha-cypermethrin. Matrix-matched calibrations were prepared. The corresponding linear regression plots and equations were provided. The samples meet the calibration. Further dilutions occurred to meet the calibration range if required.

Accuracy: Samples of M4 water or tap water were fortified with 5 and 5000 ng/L of alpha-cypermethrin. Samples of untreated sediment were fortified at 1.0 µg/kg and 400 µg/kg. Mean recovery at each fortification is presented in the Table below.

Repeatability: RSD was reported in table below and is lower than 20%..

Limit of Quantification: 5 ng/L (water), 1 µg/kg (sediment)

Table 4.1.2-69: Alpha-cypermethrin validation results from water and sediment

Sample matrix/analyte	Fortification level	Alpha-cypermethrin recovery (%) Mean (range)	RSD (%)	n
M4 water or tap water)/alphacypermethrin	5 ng/L	106 893-121)	11	6*
	50 ng/L	79 (-)	-	1
	500 ng/L	99 (96-101)	3**	4*
	5000 ng/L	117 (-)	-	1
Sediment/ alpha-cypermethrin	1 µg/kg	98 (93-102)	4	6
	400 µg/kg	110 (106-109)	5	5

For determination in water : three blank controls (two M4 water and one tap water) were tested. For determination in sediment: three blank controls (sediment) were tested.
* Among the 6 replicates, 5 were performed with M4 water and one with tap water. Among the 4 replicates, 3 were performed with M4 water and one with tap water.
** Calculated based on the results presented in the study report.

Conclusion: **The GC-MS (modified DFG S19) method for the determination of alpha-cypermethrin in sediment with an LOQ of 0.0 01 mg/kg is fully validated according to SANCO/3029/99 rev. 4. Mean recoveries and RSD are within the acceptable limits according to SANCO/3029/99 rev.4. Only one individual recovery was found to be higher than 110% at 400 µg/kg but the mean recovery remained acceptable. The GC-MS method is considered to fully support the ecotox results. For study KCA. 8.5.1.2.6, only the endpoints for sediment are used in the risk assessment.**

Report:	CA 4.1.2/66 Hoess S., 2013 Chronic toxicity of Alpha-Cypermethrin to Caenorhabditis elegans exposed via spiked sediment according to ISO guideline 10872 (2010) 2013/1250848
Guidelines:	ISO 10872 (2010)
GLP:	Yes (Landesamt fuer Umwelt, Messungen und Naturschutz Baden-Wuerttemberg, Karlsruhe Germany)

Report:	CA 4.1.2/67 Anonymouns, 2016 Excerpt of raw data supporting analytics used in ecotoxicological studies) 2016/1232573
Guidelines:	not stated
GLP:	not stated

Principle of the method:

The method is almost identical to the method described in study KCA 8.2.5.3/002 03 (see Study no. 11 here above) with the exception that the aliquot is filtered before concentration and injection. The amount of sample and solvent were also adapted and the GC-MS (monitored ions : m/z 207, 209 and 211) conditions are slightly different (injection temperature, temperature program).

- **Matrix:** Formulated sediment according to ISO 10872.

Specificity/Interference	No significant interference from the blank control was observed. Chromatograms were provided for the control (sediment), a standard solution, fortified sample at LOQ and test samples. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
Linearity:	Method was found to be linear: r2 ≥ 0.996 in the 3.0 – 500 ng/mL (n = 7). Calibrations were prepared in toluene. In the raw data (*DocID 2016/1232573 – Excerpt of raw data supporting analytics used in ecotoxicological studies)*, matrix matched quality control samples (QC) have been analysed during the quantitative analysis to confirm the absence of matrix effects. Levels tested were 3 and 500 ng/L. No significant matrix effects were observed. The corresponding linear regression plots and equations were provided. The samples meet the calibration range. Further dilutions occurred to meet the calibration range if necessary. For water: Method was found to be linear: $r^2 \geq 0.999$ in the 0.5 – 50.0 ng/mL (n = 7) for alpha-cypermethrin. Calibrations were prepared in toluene. The corresponding linear regression plots and equations were provided. For sediment: Method was found to be linear: $r^2 \geq 0.999$ in the 0.25 – 50.0 or 100 ng/mL (n ≥ 7) for alpha-cypermethrin. Matrix-matched calibrations were prepared. The corresponding linear regression plots and equations were provided. The samples meet the calibration. Further dilutions occurred to meet the calibration range if required.

Accuracy: Samples of sediment were fortified with 0.1 and 50 mg/kg of alphacypermethrin. Mean recovery at each fortification level is presented in the Table below.

Repeatability: RSD was reported in table below and is lower than 20%.

Limit of Quantification: 0.1 mg/kg sediment

Table 4.1.2-70: Alpha-cypermethrin validation results from sediment by GC-MS

Sample matrix/analyte	Fortification level	Alpha-cypermethrin recovery (%) Mean (range)	RSD (%)	n
Sediment/ alpha-cypermethrin	1 µg/kg	105 (100-109)	5	3
	50 µg/kg	110 (101-116)	7	3

One blank control has been tested

Conclusion: **The GC-MS method is considered suitable for the quantification of alpha-cypermethrin in sediment matrices with an LOQ of 0.1 mg/kg. The method supports the endpoints derived from study KCA 8.2.5.4/002.**

Report:	CA 4.1.2/68 Gilbert D, Goth M., Class T., 2012 Alpha-Cypermethrin (BAS 310 I): A study on the chronic toxicity to the sediment dweller Lumbriculus variegatus 2012/1205915
Guidelines:	OECD 203 (1992), OECD 225 Sediment-water Lumbriculus toxicity test using spiked sediment (October 2007)
GLP:	Yes (Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden, Germany)

Remark: CA 4.1.2/68 (2016/123573) is also considered here.

Principle of the method:

Alpha-cypermethrin was determined in the water samples (overlaying water samples) by liquid/liquid partition into dichloromethane and GC/MS determination (column Agilent VF-5ms, 30 m ×0.32 mm, 0.25 µm, SIM mode, monitored ion: m/z 207) based on internal calibration (lambda cyhalothrin). The extraction method is similar to the one described in study KCA 8.2.5.3/001-and 002 03 (studies No. 10 and 11) despite that amounts were adapted and that dichloromethane has been used instead of hexane. Water samples (75 mL) are extracted in separatory funnels 3-times with each 10 mL of dichloromethane. The combined organic extract was filtered through a funnel fitted with glass wool and anhydrous sodium sulfate. The sodium sulphate was washed two times with each 5 mL of dichloromethane. The extract was concentrated using a rotary evaporator to about 5 mL. The 5 mL-residue was transferred into 15 mL glass centrifuge vial, the evaporation flask was rinsed with 5 mL of dichloromethane and
0.25 mL of the 10-ng/mL IS solution was added. The extract was concentrated using a N2-evaporator at about 40°C water bath temperature to about 1 mL. The extract was transferred into a 1 mL autosampler vial and the remaining dichloromethane was evaporated. Alpha-cypermethrin was determined in the sediment samples by modified DFG S19 method and GC/MS (Agilent VF-5ms, 30 m × 0.32 mm, 0.25 µm, SIM mode, monitored ion: m/z 207) based on internal calibration (lambda cyhalothrin). The extraction method is identical to the one described in study KCA 8.2.5.3/002 03 (study No. 11) despite that amounts were adapted.

Matrix:

- reconstituted water according to OECD guideline No. 203, characteristics: 2.53 mmol/L total hardness, 0.9 mmol/L alkalinity up to pH 4.3, 7.94 pH, 678 µs/cm conductivity. Fortification were performed on tap water or M4 medium.
- Sediment: artificial substrate as described in OECD guideline 225.

Specificity/Interference	No significant interference from the blank controls was observed. Chromatograms were provided for the blank solutions (tap water, sediment, untreated overlying water), standard solutions, internal standard, fortified samples at LOQ and higher fortification levels and test samples at the initiation and at the end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.

Linearity: For water and sediment: Method was found to be linear : r2 ≥ 0.999 in the 0.3– 100 ng/mL (n = 7) for alpha-cypermethrin. Calibrations were prepared in toluene. No matrix-matched calibration was used. In the raw data (*DocID 20161232573 – Excerpt of raw data supporting analytics used in ecotoxicological studies*), matrix effects were assessed by analysis of matrix-matched quality control samples (QC) prepared for the test item and the internal standard; by calculating the ratio of both, any occurring matrix effect is accounted for and the ratio obtained is comparable to the solvent standards. The corresponding linear regression plot and equation were provided. The samples meet the calibration. Further dilutions occurred to meet the calibration range when required.

Accuracy: Samples of tap water were fortified with 5 and 500 ng/L of alpha-cypermehtrin. Samples of untreated sediment were fortified at 17.0 µg/kg and 1667 µg/kg dry sediment weight. Mean recovery at each fortification is presented in the Tablebelow.

Repeatability: RSD was reported in table below and is lower than 20%..

Limit of Quantification: 5 ng/L for water and 17 µg/kg sediment (dry)

Table 4.1.2-71: Alpha-cypermethrin validation results from water and sediment by GC-MS (modified DFG S19)

Sample matrix/analyte	Fortification level	Alpha-cypermethrin recovery (%) Mean (range)	RSD (%)	n
Tap water)/alpha-cypermethrin	5 ng/L	87 (71-95)	16	[3]
	500 ng/L	101 (99-102)	2	3
Sediment/ alpha-cypermethrin	17 µg/kg	106 (103-108)	3	3
	1667 µg/kg	102 (100-106)	3	3

Stability of standard solutions about 13 days and extracts during the course of the study was demonstrated by consistent GC-MS results.
For determination in water : one blank control (tap water) was tested. For determination in sediment: two blank controls (sediment) were tested.

Conclusion: **The modified DFG S19 method (GC-MS) for sediment was already considered as fully validated in the 0.001 – 0.4 mg/kg range (see KCA 8.2.5.3/03). Acceptable validation data were also provided in the 0.1 – 50 mg/kg (3 replicates at each level) (see KCA 8.2.5.4/002 – Study No. 12) and here acceptable validation data are obtained in the 0.017 – 1.7 mg/kg (3 replicates at each level). Overall, the method shows suitable mean recoveries and RSD although the number of replicates at some fortification levels is only 3. Therefore, the method is considered suitable for the determination of alpha-cypermethrin in sediment with an LOQ of 0.001 mg/kg and in a range from 0.001 to 50 mg/kg. The method is therefore considered "fit for purpose" and the ecotox results in study KCA 8.2.5.4/001 are reliable.**

GLP:	Yes (Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Note: the report on the analytical phase by Obermann M. 2008, 302191_1, BASF Agricultural Center Limburgerhof, Ecology and Environmental Analytics, Germany, GLP was part of the ecotox study.
Matrix**:** Mixing-water Reconstituted water (M4 medium according to Elendt, prepared based on ultrapure deionized water); characteristics: 1.0 mmol/L total hardness, pH = 7.5-8.5, 250 µS/cm conductivity

Principle of the method APL0528/02:
The samples with a concentration of 5 µg/L (500 mL) were filled into a separating funnel. The glass bottles were washed with 50 mL dichloromethane and were added to the sample in the funnel. After vigorously shaking for 3 minutes, the phases are allowed to separate. The lower phase was run through a filter funnel with sodium sulfate, in a 100 mL round bottom flask. After repeating this procedure with the remaining water phase, the combined organic phases were reduced to dryness by rotary evaporation by 30°C water bath and 615 mbar. The residue in the flask was eluted with 1 mL ethanol, shaken carefully and 4 mL water added. The solution was then injected in HPLC-MS/MS (Waters X-Bridge C18, 50 mm x 3 mm i.d, 3.5 µm particle size; mobile phase A: water/formic acid 1000/1 + 4 mM HCOONH4 and mobile phase B: methanol/formic acid 1000/1 + 4 mM HCOONH4, monitoring: m/z 433_ 191). External calibration was used for quantification.

Table 4.1.2-72: Validation data for method APL0528/02 (LC-MS/MS) to determine alpha-cypermethrin in water

Study/Matrix/ analyte	LOQ	Linearity Range (µg/L) (n) Correlation coefficient r	Fortification levels	Specificity and interferences
CA 4.1.2/69 Reconstituted water (M4 medium according to Elendt)/alpha-cypermethrin	0.0004 mg formulation/L (= 0.00002 mg a.i./L)	0.001 – 0.02 mg BAS 310 51 I/L Range (5 concentrations, Duplicate injection).	Fortified samples were prepared at levels in the 0.0004 – 0.01 mg BAS 310	No significant interference from the blank control was observed. Chromatograms were provided for
		r ≥ 0.998 The corresponding linear regression plot and equation were provided. The concentration of the samples are within the calibration range, otherwise dilution or concentration steps occurred to meet the calibration range	51 I/L range. Mean recovery at each fortification level is presented in the Table below. RSD was not reported but was calculated based on the available results.	the blank solution (M4 algal medium), a standard solution and test samples at initiation and end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard
CA 4.1.2/70 Mixing-water Reconstituted water (M4 medium according to Elendt)/alpha-cypermethrin	0.01 mg formulation/L (= 0.0005 mg a.i./L)	0.004 – 0.04 mg BAS 310 51 I/L range (4 concentrations, duplicate injection). r ≥ 0.992 Calibration curve and regression equation provided. The concentration of the samples are within the calibration range, otherwise dilution occurred to meet the calibration range	Fortified samples were prepared at levels in the 0.01 – 0.2 mg BAS 310 51 I/L range. Mean recovery at each fortification level is presented in the Table below. RSD was not reported but calculated from the available results.	No significant interference from the blank control was observed. Chromatograms were provided for the blank solution (mixing-water medium), a standard solution and test samples at initiation and end of the test. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard

Note: the absence of matrix effects was not demonstrated but any naturally occurring matrix would have been removed by the extensive liquid-liquid partitioning of the water samples.

Table 4.1.2-73: Mean recovery and RSD for method APL0528/02 (LC-MS/MS) to determine alphacypermethrin in water

Study/Matrix/Analyte	Fortification levels (mg formulation/L)	Mean* recovery % (range)	RSD %*	n*
CA 4.1.2/69 Reconstituted water (M4 medium according to Elendt)/alpha-cypermethrin	0.0004**	110.2 (108.7, 112.5)	1.5	4
	0.01**	98.7 (81.7, 115.6)	18	4
CA 4.1.2/70 Mixing-water Reconstituted water (M4 medium according to Elendt)/alpha-cypermethrin	0.01**	95.6 (88.4-103.9)	8.3	4
	0.2**	92.7 (84.7-100.6)	8.7	4

In KCP 10.2.1/002: The stability in M4 medium over a period of 2 days at room temperature could not be confirmed since slightly degradation was observed. In KCP 10.2.1/001, the stability in water over a period of 4 days at room temperature could not be confirmed since slightly degradation was observed. Two controls were tested concurrently with the test.
* results of fortified samples at the initiation and at the end of the test, each injected in duplicated. Mean recovery and RSD recalculated based on the results at the initiation and at the end of the test.
** corresponding to ~ 0.00002 mg a.s./L and 0.0005 mg a.s./L, respectively in KCP 10.2.1/001 and corresponding to ~ 0.0005 mg a.s./L and 0.01 mg a.s./L, respectively in KCP 10.2.1/001.

Conclusion: **Mean recoveries and RSD at each fortification level tested were within the acceptable limits according to SANCO/3029/99 rev.4. for the determination of alpha-cypermethrin by LC-MS/MS according to method APL0528/02. The method is therefore considered as sufficiently validated and supports the corresponding ecotox results.**

Report:	CA 4.1.2/71 [redacted] 2008 BAS 310 51 I - Acute toxicity in the bobwhite quail (Colinus virginianus) after single oral administration (LD50)
	2008/1051526
Guidelines:	EPA 71-1, EPA 540/9-85-007,EPA 540/9-82-024,EPA 850.2100
GLP:	Yes (Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method:

Samples were diluted with acetonitrile/highly deionized water 1/1 v/v. Aliquots of the dilutions were used for HPLC-UV analysis (column: Luna 2.5 µm C18(2)-HST, 50 m x 2 mm for determination during the test and Gemini 3 µm C18, 50 ×2 mm in the analytical phase report, eluent 65% acetonitrile + formic acid (1,000 + 1 mL)/35 % highly deionized water + formic acid (1,000 + 1 mL, detection at 202 nm). External calibration was used for quantification. Matrix was drinking water.

Specificity/Interference	No interferences occurred at the retention time of the analyte in the control sample (drinking water). Chromatograms were provided for standard solutions, blank and samples. The identity was confirmed on the basis of the selected wavelength and the retention time. The method is used for dose verification of known substances and known nominal concentrations. Hence, no additional confirmatory technique is necessary.
Linearity:	Method was found to be linear : in the ~ 0 – 150 mg/L and ~ 0 – 475 mg/L range (3 different concentrations, duplicate injection). Calibration in acetonitrile/highly deionized water 1/1 v/v, further diluted with acetonitrile. The calibration curve was provided but not the regression equation and the correlation coefficient. However, since the calibration curve showed good linearity, no further data are required.
Limit of Quantification:	83.5 mg/L (lowest calibration standard concentration, corresponding to 4.1% w/w).

Table 4.1.2-74: Dose verification and stability data for BAS 310 51 I in drinking water

Sample matrix/analyte	Nominal concentraton %w/w (g formulation/100g)	Nominal concentration in mg formulation/kg bdw Mean (range)	% of nominal concnetration	N*
Drinking water /BAS 310 51I	**Dose verification**			
	5 (corr. to 100 mg/L)	500	96.6	2
	10 (corr. to 200 mg/L)	1000	96.2	2
	20 (corr. to 4000 mg/L)	2000	96.0	2
Sediment/ alpha-cypermethrin	**Stability**			
	0.99 (0h)	-	100.0	2
	0.99 (6h)	-	.102.0	2

Conclusion: **83.5 mg/L (lowest calibration standard concentration, corresponding to 4.1% w/w the method is considered to be "fit for purpose" taken into account the overall results as the absence of interferences and the good recoveries obtained. Additionally, it is noted that the same method has been used in study KCA 8.1.1.1/01 for the determination in 0.5% CMC in drinking water and with similar validation data at similar levels. The results of study KCP 10.1.1.2/001 are therefore supported by the analytical method.**

GLP:	Yes (Landesamt fuer Umwelt, Messungen und Naturschurz, Baden-Wuerttemberg, Karlsruhe, Germany)

Principle of the method L0020/01 = 567/0 (Method for determination of Alpha-cypermethrin in plant matrices):

All matrices except for commodities with high fat content:
Alpha-cypermethrin or cypermethrin is extracted with a 70:25:5 methanol/water/hydrochloric acid (2N) mixture. After centrifugation, an aliquot of the extract is partitioned into cyclohexane. Silica gel SPE column is used for further purification, if required. Final determination is performed by LC-MS/MS after reconstitution in methanol/water 80/20 v/v using the ammonium adduct of cypermethrin (Phenomenex Columbus C18 column, 2.0 mm × 100 mm, 5 µm particle size, mobile phase A: 4 mM ammonium formate + 0.1% formic acid in water and mobile phase B: 4mM ammonium formate + 0.1% formic acid in methanol with gradient elution [0 _ 0.5 min: 70/30, 0.6 → 4.0: 5/95, 4.2 → 6.0: 70/30], ESI positive mode for matrices containing little to no matrix interferenceor Phenomenex Synergi Max-RP column, 4.0 mm × 20 mm, 2 µm particle size, mobile phase A: 4 mM ammonium formate + 0.1% formic acid in water and mobile phase B: 4mM ammonium formate + 0.1% formic acid in methanol with gradient elution [0 min: 40/60, 0.6; 4 → 5 min: 0/100, 5.1 → 7.0: 40/60], ESI positive mode for matrices requiring more separation of matrix interferences). External calibration was used for quantification.
For commodities with high fat content:
Alpha-cypermethrin or cypermethrin is extracted with acetonitrile/n-hexane. After centrifugation and further partitioning step with n-hexane, the acetonitrile phase is diluted for LC-MS/MS determination (LC-MS/MS characteristics: see above). Due to the low amount of sample material the following changes to the method were made in studies KCP 10.3.1.6/001 and /005: Pollen: 0.5 g of pollen was extracted with 10 mL acetonitrile and 4 mL iso-hexane. Nectar: 1 g of nectar was extracted with 10 mL methanol/water 80/20. An aliquot of 1 mL of the extract was partitioned into 5 mL cyclohexane.
For study KCP 10.3.1.6/007, the method for all matrices except for commodities with high fat content was used;
no SPE clean-up was necessary. Minor modifications were used compared to the actual method:

- 0.25g pollen and nectar and 2.5g flowers was used instead of 5g in method 567/0
- The same extraction solvent was used but different volumes because of the different weight. The ratio between volume and weight was retained.
- The principle of the following clean-up is the same; only used volumes are different: 2 mL aliquot of the extract was used instead of 1 mL. In both cases 5 mL cyclohexane were used for liquid/liquid extraction. 5 mL of the cyclohexane phase was used for further steps instead of 3 mL. The cyclohexane was evaporated to dryness and taken up with 2 mL methanol/water instead of 1 mL.
- A similar but quiet different mobile phase was used. In the actual method water + 0.1% acetic acid, methanol + 0.1% acetic acid and 5 mM ammonium acetate in methanol were used. In method 567/0 ammonium formate + 0.1% formic acid in water and 4 mM ammonium formate + 0.1% formic acid in methanol was used.

Mobile phase composition and gradient elution at 0.35 mL/min as follows:

Time (min)	Mobile phase A : water+ 0.1% acetic acid	Mobile phase B: 5 mM ammonium acetate in methanol	Mobile phase C: methanol + 0.1% ascetic acid
0.00	11%	4%	85%
7.01	1%	4%	95%
9.01	1%	4%	95%
9.03	11%	4%	85%
11.00	11%	4%	85%

- Calibration standards were prepared in acetonitrile/water 1/1 v/v instead of methanol/water 80/20 v/v in 567/0.
- In 567/0, two possible columns were presented: Phenomenex Columbus C18 100 mm ×2 mm, 5 µm or Phenomenex Synergi Max RP 20 mm ×4 mm, 2 µm. In study KCP 10.3.1.6/007, the column Phenomenex Ultracarb 5 µm ODS 150 mm × 3.2 mm, 5 µm was used.
- For Study KCP 10.3.1.6/008, the SPE clean up step only occurred for pollen samples. Modifications were made to the original method 567/0 in order to adapt the method to the needs of the study (improvement of the extraction and reduction of matrix effects):
- The stock and fortification solutions were prepared in acetonitrile + 0.1% formic acid instead of acetone in 567/0.
- The whole nectar material (0.07 – 1.6g), approx. 0.2 g of pollen and 2.0 g of flower material were used for the extraction instead of 5 g in 567/0.
- The same extraction solvent was used. The ratio between the weight of the sample and extraction solvent volume was retained (1/20). Extraction (for pollen and flower samples) was done twice instead of one extraction with 567/0. Nectar samples were extracted one time and the ratio between the weight of the sample and extraction solvent volume was 1/40.
- The principle of the clean-up by liquid/liquid partition with cyclohexane was the same; only volumes of the extracts were different: 2 mL aliquot was taken instead of 1 mL. In both cases, 5 mL cyclohexane were used for liquid/liquid partition and 3 mL of the cyclohexane phase were used for the further steps. The cyclohexane was evaporated to dryness and reconstituted in 3 mL methanol/water 80/20 v/v instead of 1 mL.
- The column Phenomenex Ultracarb 5 µm ODS (30) 50 mm ×4.6 mm was used. The column is similar to Phenomenex Columbus C18 100 mm ×2 mm, 5 µm used in 567/0.

Mobile phase composition and gradient elution at 0.35 mL/min as follows:

Time (min)	Mobile phase A :4 mM ammonium formate in water +0.1% formic acid	Mobile phase B: 4 mM ammonium formate in methanol + 0.1% formic acid
0.00	10%	90%
7.00	1%	99%
10.00	1%	99%
10.01	10%	90%
12.00	10%	90%

Matrices: Nectar, pollen, flowers

Specificity/Interference:	No significant interference from the blank controls (nectar [combs, forager bees], pollen [combs and forager bees], flowers, nectar and pollen) was observed except in one sample of pollen (forager bees) in the study No. 365576 (part of study S09-00811 – KCP 10.3.1.6/001). A "retain" control specimen was therefore analysed and no residues of alpha-cypermethrin were obtained. Chromatograms were provided for control samples (nectar only), a standard solution, a fortified sample at the LOQ for nectar and pollen and test samples of nectar and pollen for study No. 365576 (part of study S09-00811) and for control samples (nectar and pollen), a standard solution, a fortified sample at the LOQ for nectar and pollen and test samples of nectar and pollen for study No. 365577 (part of study 50391040 – KCP 10.3.1.6/005). In study S13-01463, chromatograms were provided for a standard solution, controls (pollen, nectar and flower), fortified nectar/pollen/flower at 0.01 mg/kg and treated nectar/pollen/flower. In these chromatograms, two peaks are visible whereas they were not visible in the chromatograms of the other studies. The second peak is interference/matrix separated from the analyte and this was already observed in the original validation of method 567/0 in dry and fat matrices. In study S14-00950, chromatograms were provided for standards (calibration in solvent and matrix-matched calibration), controls (nectar/pollen/flower), fortified nectar/pollen/flower at 0.01 mg/kg and treated nectar/pollen/flower at both mass transitions. The retention times of the reference item standards matched the retention times in extracts from fortified samples and from treated samples. The method is highly specific by the monitoring of two m/z transitions.

Linearity:	In study No. 365576, method was found to be linear: r ≥ 0.999 for both transitions in both matrices. Correlation coefficients together with regression equations were provided for both transitions and for both matrices. A typical calibration curve was only presented for the 433 _ 191 transition in nectar in the ~ 0.005 – 2.5 ng/mL range (n = 6, duplicate injection). Calibration occurred in solvent. Matrix-matched quality control samples match solvent standard at a concentration of 0.005 mg/kg and no significant matrix effects were therefore observed. The concentration of the samples were within the calibration range. In study No. 365577, a typical calibration curve was also provided for the 433 → 191 m/z transition in the 0.005 – 2.5 ng/mL range (n = 6, duplicate injection, r > 0.999). Calibration occurred in solvent. The absence of matrix effects was not demonstrated within the study. The analysis was conducted using the same analytical method as in Study No. 365576 in which matrix effects were addressed. In study S13-01463, method was found to be linear in the 0.02 – 100 ng/mL range with correlation coefficient > 0.999 (n = 10, single injection, calibration in acetonitrile/water 1/1 v/v, calibration curve and regression equation provided). The report mentioned that no significant matrix effects were observed (matrix effects < 20%) allowing the use of calibration in solvent. The raw data were however not reported. The concentration of the samples are within the calibration range. Dilution may occur if necessary. In study S14-00950, method was found to be linear in the 0.03 – 100 ng/mL for nectar (n=9, single injection, calibration in methanol/water 80/20 v/v, r =0.9998, m/z 433→191), in the 0.03 – 100 ng/mL for pollen (n=9, single injection, matrix-matched calibration, r = 0.9995, m/z 433 → 191) and in the 0.03 – 100 ng/mL in flowers (n = 9, single injection, matrix-matched calibration, r = 0.9994, m/z 433→191). Matrix effects (based on the mean response factor obtained with calibration in solvent and matrix-matched calibration at different levels) were not found for nectar samples. In the contrary, significant matrix effects were observed for analysis of pollen and flower samples (24 and 20%, respectively) leading to the use of matrix matched calibrations for these matrices.

Accuracy: Fortified samples were prepared at levels in the 0.01 – 0.1 mg/kg range. Mean recovery at each fortification level is presented in the Table below. Some procedural recoveries were also performed in the course of the study No. 365576 (KCP 10.3.1.6/001): recoveries in nectar (combs) were found to be 88.8 (n = 1) and 96% (n = 1) at 0.01 and 0.1 mg/kg, respectively and recoveries in pollen (combs) were found to be 60.8 and 83.6 % (n = 2, mean = 72.2%) at 0.01 mg/kg and 75 and 79.6% (n = 2, mean = 77.3%) at 0.1 mg/kg. Procedural recoveries were also reported in study No. 365577 (KCP 10.3.1.6/005): recoveries in nectar were found to be 71.3 (n = 1) and 86 % (n = 1) at 0.01 and 0.1 mg/kg, respectively and recoveries in pollen were found to be 75.2 and 70.0 % (n = 2, mean = 72.6%) at 0.01 mg/kg and 74.2 and 80.2% (n = 2, mean = 77.2%) at 0.1 mg/kg.

Repeatability: The RSD was below 20% in each case.

Limit of Quantification: 0.01 mg/kg in each matrix

Table 4.1.2-75: Alpha-cypermethrin validation results from nectar and pollen by method L0020/01 (Study CA 4.1.2/73)

Sample/analyte	Fortification level (mg/kg)	m/z 433 ⟶ 191			m/z 435 ⟶ 193		
		Mean recovery % (range)	RSD %	n	Mean recovery % (range)	RSD %	n
Nectar/alpha-cypermehtrin	0.01	88.3 (86.8-89.5)	1.2	5	89.2 (84.3-92.0)	3.3	5
	0.1	91.3 (88.0-98.0)	4.3	5	91.0 (87.5-96.0)	3.5	5
Pollen/alpha-cypermehtrin	0.01	82.5 (76.8-88.8)	5.8	5	89.7 (87.2-92.0)	2.3	5
	0.1	81.0 (76.2-85.8)	5.1	5	81.7 (76.4-86.2)	4.4	5

Control specimens of pollen and nectar were received and analysed. The residue concentration in ine control specimen (pollen from forager bees) equaled the concentration of residues detected in the treated specimen. A “retain” control specimen was therefore analysed and no residues of alpha-cypermethrin were obtained.

Table 4.1.2-76: Procedural recoveries of alpha-cypermethrin (quantifier and qualifier transitions) in nectar, pollen and flowers (CA 4.1.2/75 – study S13-01463

Sample/analyte	Fortification level (mg/kg)	m/z 433 ⟶ 191			m/z 435 ⟶ 193		
		Mean recovery % (range)	RSD %	n	Mean recovery % (range)	RSD %	n
Nectar*/alpha-cypermehtrin	0.01	75 (56-85)	16	5	73 (51-84)	18	5
	0.1	102 (102)	-	4	104 (100-106)	2	4
	1	86 (70-106)	18	5	88 (69-108)	20	5
Pollen/alpha-cypermehtrin	0.01	78 (70-92)	11	5	88 (77-99)	11	5
	0.1	101 (99-103)	2	4	100 (97-103)	3	4
	15	90 (75-98)	10	5	89 (73-97)	11	5
Flowers/alpha-cypermehtrin	0.01	70 (56-91)	19	5	78 (61-96)	16	5
	0.1	85 (78-91)	6	4	86 (78-90)	6	4
	10	71 (60-84)	16	5	71 (61-83)	15	5

* prepared by dilution of honey with water (honey/water 1/2 v/v).
The most sample extracts were analysed within 24 hours after extraction and stability was not checked. Some sample extracts were analysed within 72 hours. The recoveries of these samples show values approx. 100% and therefore were regarded as stable.

Table 4.1.2-77: Procedural recoveries of alpha-cypermethrin (quantifier transition, results for qualifier transition were not reported) in nectar, pollen and flowers (CA 4.1.2/77 – study S14-00950)

Sample/analyte	Fortification level (mg/kg)	m/z 433 →191		
		Mean recovery % (range)	RSD %	n
Nectar*/alpha-cypermethrin	0.01	93 (82-101)	8	5
	5	93 (86-102)	8	5
Pollen/alpha-cypermethrin	0.01	81 (71-87)	8	5
	15	70 (67-74)	5	5
Flowers/alpha-cypermethrin	0.01	77 (61-91)	17	5
	15	71 (51-83)	20	5

* prepared by dilution of honey with water (honey/water 1/3 v/v).
Three control samples for pollen and two control samples for nectar and flowers.
Nectar and flower extracts were analysed within 24 hours after extraction and stability was not checked. A few pollen extracts were analysed within 96 hours storage at 15°C in the autosampler vials. The mean recovery obtained after 96 hours storage is in the same range as the mean recovery obtained for fresh samples. Samples were therefore considered stable for at least 96 hours.

Conclusion: **The method L0020/01 (567/0) LC-MS/MS appears to be fully validated according to SANCO/3029/99 rev. 4 with an LOQ of 0.01 mg/kg in pollen and in nectar, each. Mean recoveries and RSD are all within the acceptable limits and additional validation data (procedural recoveries) from studies S13-01463 (CA 4.1.2/75=KCP 10.3.1.6/007) and S14-00950 (CA 4.1.2/77=KCP 10.3.1.6/008) confirm that the method is suitable and supports the residue trials. For flowers, mean recoveries and RSD obtained are within the acceptable limits. It should however be noted that some individual recoveries (two to three at LOQ and at 10 mg/kg level) were found to be below 70%. Nevertheless, since the mean recovery for these higher levels and RSD remain acceptable even if sometimes close to the limit, the method is considered as sufficiently validated and supporting the residue trials.**

Report:	CA 4.1.2/76 Class T., 2007 Residues of Alpha-Cypermethrin in honey and pollen 2007/1013272
Guidelines:	EEC 91/414 Annex II (Part A Section 4.2), EEC 91/414 Annex III (Part A Section 5),SANCO/825/00 rev. 7 (17 March 2004),SANCO/3029/99 rev. 4 (11 July 2000), SANCO/3029/99 rev.4
GLP:	Yes (Landesamt fuer Umwelt, und Verkehr Baden-Wuerttemberg, Stuttgart, Germany)

Report:	CA 4.1.2/77 Class T., Richter S., 2016 Expert Statement - Residues of Alpha-Cypermethrin in honey and pollen 2016/1232650
Guidelines:	not stated
GLP:	not stated

Principle of the method:
Pollen (0.5 g) was extracted overnight by 10 mL of acetone/dichloromethane 1/1 v/v, the extract was filtered over sodium sulfate, concentrated to dryness, and re-dissolved in methanol/water 8/2 v/v. Honey (nectar) (1 g) was extracted with 30 mL of water/acetone 1/2 v/v, NaCl and 10 mL of ethyl acetate/cyclohexane 1/1 v/v were added to partition the analyte into methanol/water 8/2 v/v. LC-MS/MS monitored two parent-daughter ion MRMS for quantitation (433 to 191) and confirmation (435 to 95) (Phenomenex Synergy Max RP, 20 mm ×2.0 mm, 2 µm; pre-column: Phenomenex C18, 4 mm ×3 mm, 5µm). External calibration was used for quantification.
Matrix: Pollen and Nectar.

Mobile phase composition at a flow rate of 600 µL/min:

Time (min)	Mobile phase A :4 mM ammonium formate in water +0.1% formic acid	Mobile phase B: 4 mM ammonium formate in methanol + 0.1% formic acid
0.00	40%	60%
1.00	40%	60%
4.00	0%	100%
5.00	0%	100%
5.10	40%	60%
8.00	40%	60%

Specificity/Interference: No significant interference from the blank control (nectar and pollen) was observed Chromatograms were provided for control samples (nectar and pollen), standard solutions in solvent, fortified samples at the LOQ and 10 ×LOQ for nectar and pollen and treated samples of pollen. Chromatograms were also provided for calibration in honey/nectar and in pollen. The method is highly specific by the monitoring of two m/z transitions.

Linearity:	Method was found to be linear : r ≥ 0.9998 for both transitions when calibration was prepared in solvent in the 0.1 – 10 ng/mL range (n= 3, duplicate injection). The study reports also mentioned that calibration were prepared with matrix-matched standards in the same concentration range but the correlation coefficient, together with the calibration curves and regression equations were not provided. It is also not clearly stated in the study report if the matrix-matched calibration was used to determine the concentration of alphacypermethrin in the samples and the matrix effects were not considered in order to allow the use of the calibration in solvent. In the expert statement (BASF DocID 20161232650), states that for honey/nectar, samples injected were all evaluated via matrix-matched standards whereas for pollen both calibrations (in solvent for initial injections and with matrix-matched standards for later injections) were used. Matrix effects in honey/nectar at a concentration of 10 ng/mL were found to be not significant (< 20%) but for pollen, the matrix effects were insignificant for the 433 to 191 m/z transition but not for for the 435 _ 193 m/z transition for a later injection series. Since the transitions 433 to 191 was used to quantify the pollen samples, standards in solvent as well as matrix-matched standards were considered appropriate. Correlation coefficients- together with the calibration curves and regression equations were finally also provided for matrix-matched (honey/nectar and pollen) calibrations for both transitions (n = 5 in the 0.1 – 100 ng/mL range, r ≥ 0.9969). The concentration of the samples was within the calibration range after appropriate dilution if required.
Accuracy:	Fortified samples were prepared at levels in the 0.01 – 0.1 mg/kg range. Mean recovery at each fortification level in each matrix is presented in the Table below.
Repeatability:	RSD was below 20 % except in one case. See Table below.
Limit of Quantification:	0.01 mg/kg for pollen and nectar.

Table 4.1.2-78: Alpha-cypermethrin validation results from nectar and pollen by LC-MS/MS

Sample/analyte	Fortification level (mg/kg)	m/z 433 →191			m/z 435 →193		
		Mean recovery % (range)	RSD %	n	Mean recovery % (range)	RSD %	n
Nectar (honey)/alpha-cypermethrin	0.01	97 (88-113)	11	4	87 (67-110)	23	4
	0.1	108 (103-113)	4	4	106 (99-112)	5	4
Pollen/alpha-cypermethrin	0.01	84 (68-95)	15	5*	92 (81-114)	13	7
	0.1	82 (66-92)	17	3	84 (72-94)	13	3

Control specimens of pollen and nectar were received and analysed.
* Two samples from the five were not taken into account to calculate the recovery based on the average and RSD as the response for this mass transition (but not for the 2nd transition) was presumably suppressed by an exceptional matrix effect.

Conclusion: **Together with the levels found in pollen and nectar in the corresponding residue studies (levels between 0.003 – 0.026 mg/kg for pollen, no residue found for nectar in studies performed by IBACON), the method can be considered as sufficiently accurate and precise and can be considered suitable to support the residue results on pollen and nectar.**

Report:	CA 4.1.2/78 Kleebaum K., 2014 Chronic toxicity of BAS 310 I honeybee larvae Apis mellifera L. under laboratory conditions (in vitro) 2014/1162697
Guidelines:	OECD 237 (2013) Honey bee (Apis mellifera) larval toxicity test single exposure, OECD Draft Test Guideline on Honey bee (Apis mellifera) Larval Toxicity Test Repeated Exposure (February 2014)
GLP:	Yes, (Saechsisches Staatsministrerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Principle of the method:

Verification of the test stock solution's concentration of alpha-cypermethrin in acetone was performed by reversed phase HPLC-UV with detection at 277 nm (Macherey Nagel Nucleoshell RP18, 2.7 mm × 100 mm, 2.7 µm). External calibration was used for quantification.

Mobile phase composition at a flow rate of 400 µL/min:

Time (min)	Mobile phase A: water + 0.1% (v/v) phosphoric acid (85%)	Mobile phase B: acetonitrile + 0.1% (v/v) phosphoric acid (85%)
0.00	40%	60%
7.00	10%	90%
8.00	10%	90%
8.01	40%	60%

Specificity/Interference:	No significant interference from the blank control was observed Chromatograms were provided for blank, standard solutions, fortified samples at the lowest and highest levels and sample solution to analyse. Identity was confirmed by comparison of the retention time and UV spectrum of the reference with the test item.
Linearity:	Method was found to be linear: r = 0.999 in the 3.77 – 11.42 mg/mL range (n= 5, single injection). The calibration curve and the regression equation were provided. The concentration of the samples were within the calibration range after appropriate dilution.
Accuracy:	Fortified samples were prepared at levels in the 71.4 – 154 mg/L range (corresponding to 4.75 mg/L and 9.54 mg/L after dilution). Mean recovery at each fortification level in each matrix is presented in the Table below.
Repeatability:	RSD was below 20 % except in one case. See Table below.
Limit of Quantification:	71.4 mg/L (4.75 mg/L after dilution).

Table 4.1.2-79: Alpha-cypermethrin validation results from acetone by HPLC-UV

Matrix/analyte	Fortification level (mg/L)	Mean recovery % (range)	RSD %	n
Acetone/alpha- cypermethrin	71.4	101 (100-102)	0.6	5
	154	102 (102-103)	0.7	5

Two blank samples were analysed and test item was not detected (< 30% of the LOQ).

Conclusion: **The HPLC-UV method is considered validated according to SANCO/3029/99 rev. 4 and is suitable to determine the content of alpha-cypermethrin in acetone with an LOQ of 71.4 mg/L (4.75 mg/L after dilution). The method was used for concentration control of the stock solution used to prepare feed administrated to bees in support of toxicity studies on the bees.**

Report:	CA 4.1.2/79 Class T., 2014 Outdoor aquatic mesocosm study with ME solo-formulation of Alpha-Cypermethrin (BAS 310 55 I, nominal 50 g/L) - Preparation and verification of dose solutions, analysis of water and sediment samples 2014/1246534
Guidelines:	SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	Yes, (Landesamt fuer Umwelt, Messungen und Naturschutz, Baden-Wuerttemberg, Karlsruhe, Germany)

Report:	CA 4.1.2/80 Class T., 2014 Expert Statement on aquatic mesocosm study, PTRL Ulm Germany: Outdoor aquatic mesocosm study with ME Solo-Formulation of Alpha-Cypermethrin (BAS 310 55 I, nominal 50 g/L) - Preparation and verification of dose solutions, analysis of water and sediment samples 2016/1232658
Guidelines:	not stated
GLP:	nit stated

Principle of the method:

One objective of the study was to prepare and verify dose solutions to be used for two application events in the Mesocosm GmbH Study No. 233-01 and ti verify the decline of alpha-cypermethrin in the mesocosm study. A second objective was to determine alpha-cypermethrin and its epimers in water and sediment samples originating from the above mentioned mecocosm study. For dose verification, aliquots were extracted 3-times with n-hexane or toluene, the combined extracts were concentrated to dryness and then redissolved in an appropriate volume of 10 ng/mL internal standard (IS) solution in toluene for final determination by GC/MS(NCI). For mecocosm enclosure water 1.0L of water samples were extracted in separatory funnels 4-times, each time with 50 mL of dichloromethane, also used to rinse sample bottles with screw-cap in order to extract any adsorbedanalyte. The combined organic extract was transferred into a 250-mL round bottom flask and concentrated using a rotary evaporator to about 5 mL. The remaining extract volume was transferred into a 15-mL glass centrifuge vial, another 5 mL of dichloromethane were used to rinse the round bottom flask. Using a stream of nitrogen with water bath at 40°C the extract was further concentrated to about 1 mL and transferred completely into an autosampler vial and concentrated with a stream of nitrogen to dryness. The final extract volume was then adjusted to 50 µL or 1.0 mL with 10 ng/mL IS solution (vortex and sonicate) for GC/MS (NCI) injection (Varian VF-5ms, 30 m ×0.32 mm, 0.25 µm, oven temperature: 90°C, 2 min hold, ramp with 40°C/min to 250°C, ramp with 5°C/min to 280°C, ramp with 100°C/min to 320°C, 4 min hold, monitored ion for alpha-cypermehtrin : 207 m/z and for internal standard lambda-cyhalothrin: 241 m/z). The method is nearly the same as in KCA 8.2.5.4/001 (sudy 12CT1LA – Study No. 13 here above). For sediment, a modified DFG S19 extraction/partition method approach was used. For mesocosm sediment samples, 10g of wet sediment was weighed and 10 mL of water was added. This mixture was then extracted with 20 mL of acetone and shaken for 30 min. with a horizontal shaker. Then about 3.5 g of sodium chloride and exactly 10 mL of ethyl acetate/cyclohexane 1/1 v/v were added for salting out and homogeneous liquid/liquid partition by shaking for another 30 min and centrifugation for 2 min. at 4000 rpm. Following phase separation after about 5 min, an aliquot of 14 mL of the upper organic phase was dried by filtration over anhydrous sodium sulfate and evaporated to about 1.5 mL.

The 1.5 mL were transferred into a 2-mL autosampler vial and subsequently concentrated to dryness using a N2-evaporator. The final extract volume was then adjusted to 0.2 mL with 10 ng/mL IS solution (vortex, sonicate and centrifugation using micro centrifuge filter) for GC/MS (NCI) injection (Varian VF-5ms, 30 m ×0.32 mmm, 0.25 µm, oven temperature: 90°C, 2 min hold, ramp with 40°C/min to 250°C, ramp with 5°C/min to 280°C, ramp with 100°C/min to 320°C, 4 min hold, monitored ion for alpha-cypermethrin: 207 m/z and for internal standard lambda-cyhalothrin: 241 m/z). The method was previously used and validated in study 383065 (KCA 8.2.5.3/002). The GC/MS(NCI) is able to distinguish the epimers (Cis-I) originating from epimerisation of alpha-cypermethrin
Matrix**:** natural water and sediment.

Specificity/Interference:	No significant interference from the blank control water was observed. Chromatograms were provided for the blank solution (tap water), standard solutions, fortified samples at 0.05 and 500 ng/L and mesocosm water samples. No significant interference from the blank control sediment was observed. Chromatograms were provided for the blank control (sediment), standard solutions (same as above), fortified sediment at 0.001 and 0.1 mg/kg and a mesocosm sediment sample. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
Linearity:	Method was found to be linear: r^2 = 0.9982 in the 0.3 – 100 ng/L range (5 concentrations, single/duplicate/triplicate injections depending on the concentration). Calibration occurred in solvent (same calibration for water and sediment) and the absence of matrix effects was not reported in the report but it has been stated that "*Calibration via internal standardization, where the IS is present in the extracts as well as in the calibration solutions always in nominally the same concentration, compensates in GC/MS for the following effects: Varying evaporation in the GC injection system caused e.g. by matrix components, thus it is not necessary to prepare matrix-matched standards. Thus due to the use of the IS very similar to the actual analyte, matrix-effects were not specifically assessed during the study. Furthermore, acceptable recoveries obtained throughout the study for water as well as for sediment samples indicate that the use of the IS in the final extracts and calibration solutions completely compensate for any varying matrix effect on GC injection or NCI detector response*". The corresponding linear regression plot and equation were provided. The concentration of the samples are within the calibration range, otherwise dilution occurred to meet the calibration range (mainly for higher levels in sediment samples).

Accuracy: Verification of dose solutions for mesocosm applications event 1 to 3 (extraction with n-hexane or toluene) lead to 86 to 105% (mean = 93%) of the nominal concentrations (0.19 – 140 ng/mL). Fortified samples of water were prepared at levels in the 0.05 – 500 ng/L range. Mean recovery at each fortification level is presented in the Table below. Fortified samples of sediment were prepared at levels in the 0.001 – 0.1 mg/kg range. Mean recovery at each fortification level is presented in the Table below.

Repeatability: RSD was below 20 %.

Limit of Quantification: 0.05 ng/L for water; 0.1 µg/kg for sediment (wet weight)

Table 4.1.2-80: Alpha-cypermethrin validation results from water and sediment by GC-MS(NCI)

Matrix/analyte	Fortification level	Recovery (5)	RSD %	n
Tap /pond water / alpha-cypermethrin	0.05 ng/L	105 (79-127)	11	10
	500 ng/L	87 /73-99)	13	4
Sediment /alpha-cypermethrin	0.0001 mg/kg	102 (95-116)	8	5
	0.1 mg/kg	87 (82-92)	-	2

Eight blank controls were analysed for water.
Two blank controls were analysed for sediment.

Conclusion: **The modified DFG S19 method (GC/MS(NCI)) has already been considered as fully validated in the 0.001 – 0.4 mg/kg range (see KCA 8.2.5.3/002). The validation results obtained here at the 0.1 mg/kg level confirmed the previous obtained validation results. Additionally, the current validation data indicates that a LOQ of 0.0001 mg/kg instead of 0.001 mg/kg is achievable. Both methods support the ecotox results.**

Report:	CA 4.1.2/81 Schulz L., 2012 Effects of BAS 310 55 I on earthworms under field conditions 2012/1000062
Guidelines:	SO/CD 11268-3 (1999), Kula et al. (2006) - Technical Recommendations for the Update of the ISO Earthworm Field Test Guideline (ISO 11268-3), SANCO/3029/99 rev.4
GLP:	Yes, (Saechsisches Staatsministerium fuer Umwlet undLandwirtschaft, Dresden, Germany)

Principle of the method:

The scope of analytical method was to quantify alpha-cypermethrin in soil after application of BAS 310 55 I. Alpha-cypermethrin was quantified after extraction from soil using a mixture of acetone and hexane according to slightly modified method SAMS 354-2 "Determination of Residues of alpha-cypermethrin in soils – Gas chromatographic method" and "Alphacypermethrin (CL 900049): validation of Method SAMS 354-2 for the determination of Residues in soil" (BASF DocID 1999/7001547). The scale of the method was reduced by a factor 2.5 (e.g. 20 g soil instead of 50 g soil, 120 mL extraction solvent instead of 300 mL) and the clean-up using a Florisil column was omitted because not necessary. Quantification occurred by GC-MS (Rxi 5 SIL ms by Restek, 20 m ×0.18 mm, 0.18 µm, oven program: 120°C hold 1 min, ramp 40°C/min to 240 °C hold 0.00 min then ramp of 10°C/min to 290°C, hold 4.00 min, ions 209, 207 and 171)
Matrix: Soil.

Specificity/Interference:	No significant interference from the control soil was observed. Chromatograms were provided for the three ions for the control (soil), a standard solution, fortified samples at 0.005 mg/kg and treated samples. The identity was confirmed by comparison of the retention time in the test sample with the retention time of the standard.
Linearity:	Method was found to be linear: r > 0.9994 for the three ions in the 0.125 – 5.99 ng/mL range (6 or 7 concentrations). Matrix-matched calibration was used. The corresponding linear regression plots and equations were provided.
Accuracy:	Method was found to be linear: r > 0.9994 for the three ions in th Procedural recoveries were performed at 0.005 mg/kg and 0.05 mg/kg. Mean recovery at each fortification level is presented in the Table below.
Limit of Quantification:	0.005 mg/kg dry soil.

Table 4.1.2-81: Alpha-cypermethrin validation results from soil by GC/MS (method SAMS 354-2, monitored ions: m/z 209 for quantitation, 207 and 171 for confirmation) – procedural recoveries

Sample matrix/analyte	Fortification level (mg/kg dry soil)	m/z 209			m/z 207			m/z 171*		
		Mean recovery % (range)	RSD (%)	n	Mean recovery % (range)	RSD (%)	n	Mean recovery % (range)	RSD (%)	n
Soil/alpha-cypermethrin	0.005	81.3 (72-87)	10	3	79.0 (76-84)	5.6	3	66.3 (57-75)	13.6	3
	0.05	94.3 (87-105)	10.1	3	96.3 (90-106)	8.8	3	92.0 (85-105)	12.3	3

Four controls were analysed.
Dilute solutions of the stock solution are stable on storage for at least 3 months when stored in dark at ambient temperature.
* m/z 171 was of very low intensity explaining the difficulties to obtained acceptable recoveries at the lowest level in this case.

Conclusion: **A slightly modified method compared to the method SAMS 354-2 was used here. SAMS 354-2 (GC-ECD) was previously considered as sufficiently validated according to SANCO/3029/99 rev. 4 in the 0.05 – 0.5 mg/kg range. The validation results provided here by GC-MS at the 0.05 mg/kg level confirmed the previously acceptable obtained results and the results obtained at 0.005 mg/kg indicates that the method can achieve a LOQ of 0.05 mg/kg. The method is considered fit for purpose and supports the ecological data.**

Report:	CA 4.1.2/82 Weltje L., Janson G.-M., 2013 The influence of humic acid and green algae on the toxicity of BAS 310 55 I to Daphnia magna STRAUS 2013/1404157
Guidelines:	OECD 202, EPA 850.1010 draft April 1996
GLP:	Yes, (Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the method:

Alpha-cypermethrin with its epimer (Cis-I cypermethrin) were determined in water samples by liquid/liquid extraction using dichloromethane and GC-MS determination based on internal calibration (use of lambdacyhalothrin) (Macherey Nagel Optima-5HT column, 30 m × 0.25 mm, 0.25 µm film thickness, splitless injection, injector temperature of 230 °C, oven temperature: 80°C, 1 min hold, ramp with 50°C/min to 260°C, hold for 8 min, ramp with 50°C/min to 300°C, hold for 2 min, He, 1.2 ml/min flow, SIM mode, negative chemical ionisation, monitored ion for quantitation: 207 m/z, for confirmation m/z ions 209 and 211, for internal standard: m/z 241).

Matrix:
- reconstituted water (M4 according to Elendt)
- M4- water + humic acid
- M4-water + green algae

Specificity/Interference:	No interference of the matrices with the test substance could be observed under the analytical conditions used. Chromatograms have been provided for calibration standards, controls, test samples and fortified samples at the lowest fortification level. Identity of the analysed compound was confirmed by monitoring 3 m/z ions.
Linearity:	Six standard solutions in the concentration range from 0.2 to 150 or 300 ng alpha-cypermethrin/mL (corresponding to 10 ng/L and 7500 or 14000 ng/L) were used for the linearity. The response of the method was found to be linear in this range with 2 = 0.9994. The resulting calibration graph was provided together with the regression equation. It is noted that the lowest calibration level corresponds exactly to the lowest fortification level. This will not influence negatively the results. Calibration occurred in toluene, however the absence of matrix effect was not demonstrated. The concentration of the prepared samples meet the calibration range (samples are concentrated before injection, the 10 ng/L fortified level corresponds to 0.2 ng/mL and the 1000 ng/L fortified level corresponds to 20 ng/mL). During the ecotox test, the Cis- I isomer was determined from the calibration performed with alphacypermethrin and taking into account for the response factor of the Cis-I isomer.
Accuracy:	Fortifications occurred with alpha-cypermethrin at 10 and 1000 ng/L in three types of water (M4-water, M4-water with humic acid and M4-water with green algae. Mean recovery at each fortification level is presented in the Table below.

Repeatability: RSD is provided in the table below.

Limit of Quantification: 10 ng alpha-cypermethrin/L

Table 4.1.2-82: Alpha-cypermethrin recoveries obtained from various fortified water types

Fortified samples					
Analyte	**Matrix**	**Fortified level ng/L**	**% mean recovery (range)**	**% RSD**	**n***
Alpha-cypermethrin	M4-water	10	88 (72 – 105)	16	5
		1000	102 (89 – 116)	11	5
	M4- water with humic acid	10	84 (72 – 110)	18	5
		1000	87 (78 – 101)	11	5
	M4-water with greenalgae	10	83 (70 – 106)	17	5
		1000	93 (69 – 107)	16	5

* Most of the replicates was injected twice.
Four or five controls were checked..

Conclusion: **The GC-MS method is considered sufficiently validated according to SANCO/3029/99 rev. 4. The LOQ of 10 ng a.i./L is validated. The endpoints determined in study KCA 8.2.4.1/02 are therefore considered reliable.**

Remark: A series of methods used in support of old ecotoxicity tests is also presented and assessed here below. These older methods were all used in support of ecotox studies which have been considered as relied upon in the frame of the renewal with some of them leading to critical endpoints.

Report:	CA 4.1.2/83 [redacted] 1981 WL 85871 and Cypermethrin: A comparison of their acute toxicity to Salmo gairdneri, Daphnia magna and Selenastrum capricornutum AL-511-001 Report No. SBGR.81.27
Guidelines:	EPA 850.1075, EPA 850.1010,EPA 72-1,EPA 72-2
GLP:	not stated,

Report:	CA 4.1.2/84 [redacted] 983 WL85871 and Cypermethrin: A comparative study of their toxicity to the fathead minnow Pimephales promelas (RAFINESQUE) AL-512-002 Report No. SBGR.82.298
Guidelines:	EPA 850.1075, EPA 850.1400,EPA 72-1,EPA 72-4
GLP:	not stated

Principle of the method:
Extraction of the samples was carried out with hexane (2 × 10 mL) in the separating funnels. For daphnia and algal experiments, the hexane extractant was used to rinse the test vessels. Hexane extracts of the samples were dried by passage through anhydrous sodium sulphate. The combined extracts for a sample were diluted if required and analysed by packed column GC-ECD (GC condition 1 for quantitation of most results: Varian 2 m × 6 mm ×2 mm id packed with 3% OV-1 on mesh 100-120 GCQ, column T°: 260°C, injector T°: 260°C, detector T°: 350°C, carrier gas N2, flow 0.045 l/min; for WL 85871 (alpha-cypermethrin) some determinations were made with GC condition 2: HP 3 × 6 mm × 2 mm id packed with 3% OV-1 on mesh 100-120 GCQ, column T°: 250°C, injector T°: 250°C, detector T°: .350°C, carrier gas: Argon/Methane 90/10, flow 0.033 l/min). External calibration. In study SBGR.82.298, the method used is almost identical to the method used in Study SBGR.81.277 except that 2 × 15 mL hexane were used and where necessary, the combined hexane extracts were evaporated to volume (5 mL) suitable for alpha-cypermehtrin or cypermehtrin determination using the GC-ECD. Two sets of GC operating conditions were also used, slightly amended compared to here above (GC conditions 1: HP 1.5 m × 6 mm × 2 mm id glass column packed with 3% OV-& on 100-120 mesh GCD, column T°: 270°C, injector T°: 250°C, detector T°: 300°C, carrier gas Ar/Metane 90/10, flow: 0.03 l/min; GC conditions 2: Varian 1 m × 6 mm × 4 mm id glass column packed with 31% OV-1 on 100-120 mesh GCQ, column T°: 235°C, injector T°: 260°C, detector T°: 300°C, carrier gas N2, flow: 0.04 l/min).
Matrix: drinking water

Specificity/Interference:	Cypermethrin or alpha-cypermethrin have not been identified in the control test vessels above 0.01 µg/L for study SBGR.81.277 and above 0.03 µg/L in Study SBGR.82.298. No chromatograms were provided.

Linearity:	The analytical standards for alpha-cypermethrin were made in hexane in the 2 – 200 µg/L range and for cypermehtrin in the 1 – 200 µg/L range. No other data were provided regarding the calibration and the linearity of the response for the method.

Accuracy: Fortifications occurred at 0.05 and 5.0 µg/L for cypermethrin and WL 85871. Mean recovery at each fortification level is presented in the Table below. Fortifications occurred with alpha-cypermethrin at 10 and 1000 ng/L in three types of water (M4-water, M4-water with humic acid and M4-water with green algae. Mean recovery at each fortification level is presented in the Table below.

Repeatability: RSD is also presented in the Table below and has been re-calculated based on the available results.

Limit of Quantification: In study SBGR.82.298, the LOQ is stated to be 0.03 µg/L but occasionally as low as 0.01 µg/L for cypermethrin and 0.01 or 0.02 µg/L for alphacypermethrin) but these values were not substantiated by the available data. Based on the available results, an LOQ of 0.1 µg/L can be considered as achievable for cypermethrin and 0.5 µg/L for alpha-cypermethrin but can however not be considered as fully validated.

Table 4.1.2-83: Recovery data for cypermethrin and WL 85871 in water (study SBGR.81.277) and recovery experiments from the chronic and acute toxicity studies (study SBGR.82.298)

analyte	Fortification levels µ g/L	Recoveries (range in %)	Mean recoveries (%)	RSD (%)	n
Study SBGR.81.277					
cypermethrin	0.05	80	80	0.0	3
	0.5	80	80	0.0	3
	5.0	88 - 92	92	4.3	3
WL 85871 (alpha-cypermethrin)	0.05	80 - 160	113	36.8	3
	0.5	80	80	0.0	3
	5.0	93 - 105	97	6.9	3
Study SBGR. 82.298					
cypermehtrin	0.1 – 1.0 ***	78 - 133	97	-*	26
	0.5 – 5.0****	73 - 100	90	-*	10

	2 – 10****	103 - 106	105	-**	2

In controls, concentration found was below 0.01 µg/L
The study report does not mention clearly if n well corresponds to 3 replicates or if it correspond to three injections.
* the overall RSD cannot be calculated since the individual recoveries were not displayed in the study report.
** not relevant since the number of replicates is only 2.
*** for chronic tests.
**** for acute tests.

Table 4.1.2-84: Recovery data for cypermethrin in algae/water medium (concentration added 100 µg/L for each analyte)

Concentration of selenastrum capricornutum (cells ml^{-1})	Recovery cypermethrin (%)	Recovery WL 85871 (%)
5×10^3	59	97
5×10^3	75	103
5×10^6	68	94

Conclusion: **The method was developed and validated prior to SANCO/3029/99 rev. 4 coming into force. The method is deemed fit for purpose to quantify alpha-cypermethrin at a LOQ of 0.05µg/L, bearing in mind that a newly developed method would probably yield better repeatability at low concentration levels. The method is still considered fit for purpose as 0.1 µg/L levels were assessed but no detailed data was reported. Furthermore, the endpoint in Daphnia is covered by a more recent study (KCS 8.2.4.1/02, DocID 2013/1404157).**

Report:	CA 4.1.2/85 Garforth B.M., 1982 WL 85871 and Cypermethrin: Chronic toxicity to Daphnia magna AL-523-001 Report No. SBGR.82.119
Guidelines:	US-ECO 96-325, US-954-96-325,US-305AX-446-004,US-96178/02-ASCr
GLP:	not stated

Principle of the method:
Alpha-cypermethrin and cypermethrin were extracted from water with hexane. The hexane extracts were dried by passage through a bed of anhydrous sodium sulphate, combined, evaporated to small volume, purified by HPLC and analysed by GC-ECD (1.5 m × 6 mm × 2 mm id glass column packed with 3% m-OV-1 on 100-120 mesh GCQ, column temperature: 225°C, injector temperature: 250°C, detector temperature: 300°C, flow rate 22 ml/min). External calibration. The method seems to be similar to the method described in studies No. 26 and 27 here above with some modifications. Matrix**:** water (from which algal cells were removed).

Specificity/Interference:	Chromatograms were not available in the report. Recovery rates support the fact that no significant interference was present
Linearity:	Standard solutions in the concentration range from 0.001 to 0.02 µg/mL were prepared for both alpha-cypermethrin and cypermethrin. However, the linearity of the response has not been shown (number of standard solutions prepared unknown, correlation coefficients not provided, calibration graphs and regression equations not provided). Calibrations occurred in hexane.
Accuracy:	Fortifications occurred with alpha-cypermethrin and cypermethrin at 0.1 and 0.3 µg/L in water from which algal cells had been removed. Mean recovery at each fortification level is presented in the Table below.
Repeatability:	RSD was not provided.
Limit of Quantification:	Not stated in the study report. However, based on the available results, a LOQ of 0.1 µg/L for alpha-cypermethrin or cypermethrin seems to be achievable.

Table 4.1.2-85: Recoveries obtained for alpha-cypermethrin and cypermethrin in the fortified samples of water

Fortified samples						
Analyte	**Matrix**	**Fortified level (µg/L)**	**% mean recovery**	**% mean recovery*** **	**% RSD***	**n****
Alpha-cypermethrin	Water from which algal cells had been removed	0.1	80, 80, 80, 90	82.5	6.06	4
		0.3	95	95	-	1
cypermethrin		0.1	150, 110, 80, 100	110	24.1	4
		0.3	190, 115, 115	140	30.9	4

* RSD was not provided in the study report. When present, it has been re-calculated based on the available results and assuming that the number n was well the number of replicates.
** It is not clearly stated in the study report if it is the true number of replicates or if there were several injections of a same replicate.
*** Calculated based on the available results. However, It is not clearly stated in the study report if the number of replicates is true replicates or if there were several injections of a same replicate.

Conclusion: **The method is suitable for quantification of alpha-cypermethrin in aqueous media with a limit of quantification of 0.1 µg/L. A nearly identical method was used in study CA 4.1.2/84 with a proposed LOQ of 0.05 µg/L.**

Report:	CA 4.1.2/86 Heintze A., 1997 Alphacypermethrin (AC 900049): Effects on the development of sediment-dwelling larvae of Chironomus riparius in a water-sediment system AL-523-002 Report No. 96178/02-ASCr
Guidelines:	US-ECO 96-325, US-954-96-325,US-305AX-446-004,US-96178/02-ASCr 4
GLP:	not stated

Principle of the method:
Aliquots of acetone samples were evaporated with a gentle stream of nitrogen. The residues were dissolved with acetonitrile/ultra pure water 50:50 (v/v). The analysis of alpha-cypermethrin was performed by HPLC on a C8 reversed phase column (Shandon Hypersil MOS C8, 125 mm × 4 mm, 5 µm particle size) with acetonitrile/ultra pure water (65:35 v:v) as mobile phase and UV detection at 210 nm. External calibration was used for quantification.
Matrix: acetonic stock solutions

Specificity/Interference:	No interference could be observed under the analytical conditions used in the acetone control samples at the retention time of alpha-cypermethrin. Chromatograms have been provided for a calibration standard, acetone control and a test sample (0.06 mg/L). Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.
Linearity:	Eight standard solutions in the concentration range from 0.03 to 5.0 µg/mL (mg/L) were used for the linearity (duplicate injection at each concentration). The response of the method was found to be linear in this range with a correlation coefficient = 0.999991. The resulting calibration graph was provided together the corresponding regression equation. The concentration of the prepared samples meet the calibration range except for the highest fortification level (40.0 mg/L) unless appropriate dilution occurred. Calibration occurred in acetonitrile/ultra pure water 50:50 (v/v).
Accuracy:	In the current report, it was mentioned that in the validation report 96478/01-RVF, fortifications occurred at 0.04, 0.4, 4.0 and 40.0 mg/L with alphacypermethrin and that the overall mean recovery was found to be 93% (duplicate injection of each sample) (97 +/- 4 for the 0.04 mg/L level). No details of these validation data were reported, only the results for the dose verification were reported (see Table below).
Repeatability:	RSD was not provided.
Limit of Quantification:	Stated to be 0.02 mg/L however this value seems to be not supported by the validation data of the fortification experiment.

Table 4.1.2-86: Recoveries obtained for alpha-cypermethrin in the fortified samples of acetone solutions by HPLC-UV

Concentration verification of the stock solutions for the first definitive test (mg/L)	Recovery (% of nominal)	n*
0.06	**124****	1
0.12	99	1
0.24	100	1
0.48	100	1
0.96	100	1
1.92	100	1
3.84	99	1
Concentration verification of the stock solutions for the second definitive test (mg/L)	**Recovery (% of nominal)**	**n***
0.48	94	1
0.96	95	1
1.92	97	1
3.84	94	1
7.68	96	1
15.36	96	1
30.72	96	1
Overall	**93 +/- 2.9**	

* Duplicate injection. No alpha-cypermethrin detected in the control samples.
** This value is outside the acceptable limit of 110%. The report however stated that since no blanks for alpha-cypermethrin were found in acetone controls, acceptable test substance recoveries of 97% (with a standard deviation of 4%) were found at low level (i.e. 0.04 mg/L determined for the validation of the analytical method reported in Study 96478/01) and the calibration curve was reliable even at 0.03 mg/L, the increased test substance concentration is not caused to a great extent by methodical drawbacks but rather to accidental mistakes in sampling handling. Assuming that the method has been correctly validated, this explanation seems acceptable.

Conclusion: **The method is suitable for quantification of alpha-cypermethrin in acetone solutions at a limit of quantification of 0.04 mg/L.**

Report:	CA 4.1.2/87 Klumpp M., 1998 Alpha-cypermethrin (CL 900049): Validation of a HPLC method for the determination in acetone solutions
	AL-249-002
Guidelines:	not stated
GLP:	Yes (Ministrium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart, Germany)

Principle of the method

An analytical method was validated for the determination of alpha-cypermethrin in acetone solutions of alpha-cypermethrin test substance used for a toxicity test with *Chironomus riparius*. Dilutions (0.04-40.00 mg/L) for recovery experiments were prepared in duplicate with acetone from a stock solution (alpha-cypermethrin in acetonitrile). The dilutions were placed into a water bath at about 40°C and the acetone was removed with a stream of nitrogen. The residue was made up with acetonitrile/water (50:50/v/v). The analysis was performed on a C8 reversed-phase column (Shandon Hypersil MOS C8) with acetonitrile/ultrapure water (65:35, v/v) as mobile phase at a flow rate of 1.0 mL/min and UV (photodiode array) detection at 210 nm.

Recovery findings

The overall mean recovery was 93% for alphacypermethrin test substance. Average recoveries for each matrix are summarized in Table **4.1.2-87**.

Table 4.1.2-87: Results of method validation: BAS 310 I (alpha-cypermethrin) in acetone solutions

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Acetone solution	BAS 310 I	0.04	2	97	N/A	N/A
		0.40	2	92	N/A	N/A
		4.00	2	92	N/A	N/A
		40.00	2	93	N/A	N/A
		Overall	8	93	2.6	2.8

N/A Not applicable

Linearity Linearity was tested using eight calibration standards in the range of 0.03-5.00 µg/mL. Calibration curves gave acceptable correlation coefficients ≥ 0.99. Standard solutions were prepared in acetonitrile/ultrapure water (50:50, v/v).

Specificity A confirmatory method has not been performed; however, no significant blank signals or unspecific interferences in untreated control samples were observed. Good validation results have been achieved with the primary method. The limit of detection is ≤50% LOQ (0.02 mg/kg).

Limit of Quantification	The validated limit of quantification (LOQ) for alpha-cypermethrin is 0.04 mg/kg for acetone solutions.
Repeatability	The relative standard deviation (RSD, %) over all fortification levels was below 20%. The detailed values are shown in Table **4.1.2-87**.
Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.
Standard stability	Stability of standards was not determined within this validation study.
Conclusion	**The analytical method (96178/01-RVF) is considered to be fit for purpose for the determination of residues of alpha-cypermethrin in acetone solutions.**

Report:	CA 4.1.2/88 Fuchsbichler G., 1999 Validation of method SAMS 469-2 for the determination of Alphacypermethrin (AC 900049) in pond water and treatment solutions AL-243-004
Guidelines:	EU Guideline 8064/VI/97 rev. 4 15.12.1998
GLP:	Yes (certified by Bayerisches Staatsministerium fuer Arbeit, Familie und Sozialordnung, Muenchen)

Principle of the method

An analytical method was validated for the determination of alpha-cypermethrin (CL 900049) in spray solutions. Dilutions (0.050-0.200 mg/L) for recovery experiments were prepared with acetonitrile/water (50:50, v/v) from a stock solution (formulation solutions in water). The analysis was performed with HPLC, equipped with a C_8 reversed-phase column (Shandon Hypersil MOS C8), with acetonitrile/ultrapure water (65:35, v/v) as mobile phase and UV (photodiode array) detection at 210 nm.

Recovery findings

The overall mean recoveries were 96-99% for alphacypermethrin formulation solutions. Average recoveries for each matrix are summarized in Table **4.1.2-88**.

Table 4.1.2-88: Results of method validation: BAS 310 I (alpha-cypermethrin) in spray solutions

Matrix	Analyte	Fortific. Level (mg/kg)	No. of replicates	Average Recovery (%)	Standard Deviation (±)	Coefficient of Variation (%RSD)
Fastac 10EC	BAS 310 I	0.050	2	97	N/A	N/A

		Overall	4	96	2.1	2.1
Fastac WG	BAS 310 I	0.050	2	98	N/A	N/A
		0.200	2	99	N/A	N/A
		Overall	4	99	1.3	1.3

N/A Not applicable

Linearity Linearity was tested using seven calibration standards in the range of 1-30 µg/mL. Calibration curves gave acceptable correlation coefficients ≥ 0.99. Standard solutions were prepared in acetonitrile/water (50:50, v/v).

Specificity A confirmatory method has not been performed; however, no significant blank signals or unspecific interferences in untreated control samples were observed. Good validation results have been achieved with the primary method. The limit of detection is ≤40% LOQ (0.02 mg/kg). Blanks did not exceed 30% LOQ.

Limit of Quantification	The validated limit of quantification (LOQ) for alpha-cypermethrin is 0.05 mg/kg for spray solutions.
Repeatability	The relative standard deviations (RSD, %) over all fortification levels were below 20% for all formulation solutions tested. The detailed values are shown in Table **4.1.2-88**.
Reproducibility	Reproducibility, in terms of inter-day precision, of the method was not determined within this validation study.
Extract stability	Stability of extracts was not determined within this validation study.
Standard stability	Stability of standards was not determined within this validation study.
Conclusion	**The analytical method is considered to be fit for purpose for the determination of residues of alpha-cypermethrin in spray solutions.**

Report:	CA 4.1.2/89 Jatzek H.-J., 2002 BAS 310 I - Determination of the inhibitory effect on the cell multiplication of unicellular green algae 2002/1004851

GLP:	Yes (Landesanstalt fuer Pflanzenbau und Pflanzenschutz, Rheinland-Pflanz, Mainz, Germany)

Principle of the method AL-243-008 corresponding to SAM-469-2:
The analytical method describes the determination of alpha-cypermethrin in aqueous solutions. The method is based on GC-ECD and quantitation is performed by external calibration. The sample preparation in the current study has been slightly adapted. The sample volumes to be extracted were modified and the clean-up step was omitted since in the matrix effected no interference with the measured signal. The suitability of the adaptation of the method AL-243-008 (SAMS-469-2) for the determination of alpha-cypermethrin in OECD medium was confirmed by the analyses of fortified solutions with concentrations of 0.1, 1.0, 10, 50, 100 and 1000 µg/L. Samples with nominal concentrations below 100 µg/L were extracted fivefold with 25 mL portions of hexane. Samples with nominal concentrations higher than 100 µg/L were extracted with 5 extractions of 100 mL portions. 2 µL of the combined extracts were injected. External calibration was used for quantification.
Matrix: water (OECD-medium)

Specificity/Interference:	No interference could be observed under the analytical conditions used in the acetone control samples at the retention time of alpha-cypermethrin. Chromatograms have been provided for a control and a test sample (1.0 mg/L). Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.
Linearity:	Five standard solutions in the concentration range from 2.0 to 40 mg/L (mg/L) were used for the calibration (each concentration injected twice). The response of the method was found to be quadratic in this range with a $r^2 \geq 0.9996$. Then resulting calibration graph was provided together with the corresponding regression equation. The accuracy of the standard solution was checked by ab separated second weight.
Accuracy:	Fortifications occurred at different levels with alpha-cypermethrin (see Table below)
Repeatability:	RSD was not provided.
Limit of Quantification:	Not stated in report; proposed LOQ based on the available data of 0.05 mg/L.

Table 4.1.2-89: Recoveries obtained for alpha-cypermethrin in the fortified samples of water (OECD medium) by the GC-ECD method SAMS-469-2

Alpha-cypermethrin not detectable in controls
* at test initiation
** identical organic extract analysed three days after sample extraction. 51.5% found after four days storage in the aqueous sample and stated
to be related to presumable decomposition of test substance.
** Calculated based on the results obtained with the fortified and test (Day 0) samples.

Conclusion: **The method has already been partly validated and considered suitable as a pre-registration method (but not for monitoring) for determination of alpha-cypermethrin in different water types (surface, source) with an LOQ of 0.05 µg/L. Therefore, the method is considered fit for purpose.**

Report:	CA 4.1.2/90 Kwasniok A. et al., 1991 Analysis of samples from a pond enclosure study with AC900049 (Alphacypermethrin)
	AL-123-029
Guidelines:	not stated
GLP:	Yes (Freie und Hansestadt Hamburg, Behoerde fuer Arbeit, Gesundheit und Soziales, Hamburg, Germany)

Principle of the method AL-243-008 corresponding to SAM-469-2:
The report stated that the analytical method used is the modified method SAMS-469-2 for which partial validation data (in the 0.01 – 10 µg/mL range) in pond water were generated under report ECO 97-138 – *Validation of Method SAMS-469-02 for the Determination of Alpha-cypermethrin Applied as formulation (FASTAC TM 100g/L OESC insecticide) in Pond Water*. However, in the current study, determination of alpha-cypermethrin occurred in stock solutions and not in pond water. Samples were extracted with hexane and directly injected for analysis by capillary GC-ECD without any clean-up step (J&W DB1 column, 30 m fused silica, 0.53 mm, 0.25 µm, Ar/methane: 1ml/min, oven: 60°C hold for 2 min, ramp at a rate of 25°C/min to 200°C, then a ramp at a rate of 10°C/min to 280°C, hold 5 min). External calibration.
Matrix: stock solutions.

Results of the stock solutions and a recovery sample analysed concurrently with the stock solutions are presented here below:

Analyte	Concentration in µg/mL	% recovery	n
Alpha-cypermethrin	1.27 (stock solution)	87.8	1
	127.45 (stock solution)	82.2	1
	523 (recovery sample)	106	1

Conclusion:	**No validation data for the determination of alpha-cypermethrin in the stock solutions have been provided. However, the method SAMS-469-02 (GC-ECD using capillary column) has been validated for determination in stock solutions in the Study by Huber W. 2000.**

Report:	CA 4.1.2/91 Huber W. et al., 2000 Evaluation of possible effects of a 100 g/L SC formulation (CF 06677) of AC 900049 (Alphacypermethrin) on macroinvertebrates, zooplankton and algae in pond-enclosures and determination of the ecologically acceptable concentration (EAC)

Report:	CA 4.1.2/93 Fuchsbichler G., 1999 Validation of method SAMS 469-2 for the determination of Alphacypermethrin (AC 900049) in pond water and treatment solutions
Guidelines:	AL-243-008 Report ETX-99-407 EU Guideline 8064/VI/97 rev. 4 15.12.1998
GLP:	Yes (Bayrisches Staatsministerium fuer Arbeit, Familie und Sozialordnung, Muenchen, Germany)

Analysis of aqueous treatment solutions:

The method used to analyse alpha-cypermethrin in the aqueous treatment solutions is a slightly modified version of method SAMS-469-02 (GC-ECD, capillary column), specifically the column clean-up step was eliminating due to the high concentrations of alpha-cypermethrin in solutions. The method is therefore identical to the method SAMS-469-02 described here above in Study KCA 8.2.8/05 (Study No. 31). Validation occurred in Study: *Validation of Method SAMS-469-2 for the Determination of alpha-cypermethrin (AC900049) in Pond Water and Treatment Solutions*, Report ETX-99-405, HVA 17/99. A summary of the validation data (only recoveries) obtained in that study has been reported in Appendix C of the Study KCA 8.2.8/06. The method even not fully validated appeared suitable for the determination of alpha-cypermethrin in stock solutions in the ~ 0.7 to 22250 µg/L range.

Matrices: Aqueous treatment solutions, pond water, sediment

Specificity/Interference: Not reported.

Linearity: Not reported.

Accuracy: Fortifications occurred at different levels with alpha-cypermethrin (see Table below)

Repeatability: Summary of recoveries from Study ETX-99-405 (HVA 17/99) has been provided (see Table below).

Table 4.1.2-90: % of nominal concentration of alpha-cypermethrin determined the aqueous treatment solutions with GC-ECD method SAMS-469-2

		178	85	88
		890	88	93
		4450	88	96
		22248	88	93
		Overall (n = 7)	**87 +/- 2 (RSD = 2.3%)**	**93 +/- 4.5 (RSD = 4.9%)**

Analysis of pond water samples:

The method used is method SAMS-469-02 (GC-ECD using capillary column). For details on the method, please refer to KCA 8.2.8/05 (Study No. 31) here above or in section B.5.2.4. The report stated that validation occurred in Study: *Validation of Method SAMS-469-2 for the Determination of alpha-cypermethrin (AC900049) in Pond Water and Treatment Solutions*, Report ETX-99-405, HVA 17/99. A summary of the validation data (only recoveries) obtained in that study has been reported in Appendix C of the Study KCA 8.2.8/06. It should be noted that the same method has also been partly validated.

Specificity/Interference: Interferences were below 30%. Example chromatograms were provided in the validation report AL-243-008.

Linearity: Linearity was good with r^2>0.9975. (AL-243-008)

Accuracy: Fortifications occurred at different levels with alpha-cypermethrin (see Table below)

Repeatability: Summary of recoveries from Study ETX-99-405 (HVA 17/99) has been provided (see Table below).

Limit of Quantification: 0.01 µg/L

Table 4.1.2-91: Recoveries obtained for alpha-cypermethrin determined in pond water with GC-ECD method SAMS-469-2

Analyte	Matrix	Concentration µg/L	% recovery obtained during validation (data taken from HVA 17/99 – ETX-99-405 and presented in Appendix C ofStudy ETX-99-101) (% range) [n] %RSD	Procedural recoveries (data from Study HVA 20/99)
Results obtained during validation and procedural recoveries

		0.05	-	82
		0.1	-	89.2 (92, 87) [n = 2]
		0.5	-	80
		1.0	-	95
		2.0	85 +/- 3 (84, 81, 84, 87, 87) [n = 5] %RSD = 3.0*	99.3 (94, 100, 104) [n = 3]
Results for determination in pond water at Day 0				
Alpha-cypermethrin	Pond water	0.015 (corresponding to treatment with the aqueous treatment solution of 178 µ g/L)	113 [n = 2]	-
		0.075 (corresponding to treatment with the aqueous treatment solution of 890 µ g/L)	92 [n = 2]	-
		0.375 (corresponding to treatment with the aqueous treatment solution of 4450 µ g/L)	109 [n = 2]	-
		1.875 (corresponding to treatment with the aqueous treatment solution of 22248 µ g/L)	111 [n = 1]	-

* Calculated based on the available results.

Stability of the samples:
Storage stability in pond water was investigated after 3 and 6 day-storage at 2 fortification levels 0.1 and 2 µg/L). Results showed that residues were stable for 6 day-storage under refrigerated conditions.

Analysis of sediment samples:
The method used is method SAMS-354-02, more than likely in the GC-ECD mode. SAMS-354-02 GC-ECD was considered suitable for the determination in soil with a validated working from 0.05 to 0.5 mg/kg and an LOQ = 0.05 m /kg. However, in the current study, validation in sediment occurred at lower levels (0.01 – 0.5 mg/kg). The report stated that validation occurred in Study: *Validation of Method SAMS-354-2 for the Determination of alpha-cypermethrin (AC900049) in Sediment*, Report ETX-99-407, HVA 19/99. A summary of the validation data (only recoveries) obtained in that study has been reported in Appendix C of the Study KCA 8.2.8/06.

Specificity/Interferences: Interferences were below 30% of the LOQ (AL-243-007). Example chromatograms are shown in AL-243-007.

Linearity: Calibration over a range of 0.005-0.02 µg/mL. Regression coefficients were good with r^2>0.9948.

Accuracy: Summary of recoveries obtained in Study ETX-99-405 (HVA 17/99) has been provided (see Table below)

Repeatability: See Tables below

Limit of Quantification: 0.01 mg/kg

Table 4.1.2-92: Recoveries obtained for alpha-cypermethrin determined in sediment with GC-MS method SAMS-354-2

Analyte	Matrix	Concentration mg/kg	% recovery obtained during validation (data taken from HVA 19/99, ETX-99-407 and presented in Appendix C of Study ETX-99-101) (% range) [n] %RSD	Procedural recoveries (data from Study HVA 20/99)
Alpha-cypermethrin	Sediment	0.01	83+/- 9	89 +/- 7
			(97, 86, 75, 77, 81) [n = 5] %RSD = 10.8*	(82, 88, 86, 100, 88) [n = 5] %RSD = 7.9*
		0.05	-	88
		0.1	-	100 (100, 100) [n = 2]
		0.2	-	80 (78, 81) [n = 2]
		0.5	86 +/- 12 (93, 103, 76, 76, 82) [n = 5] %RSD = 13.9*	-

* Calculated based on the available results.

Conclusion: **The method is considered suitable for the quantification of alpha-cypermethrin in pond water as well as in sediment. Although this particular method does not cover the lowest test concentration of 0.6 ng/L, the relevant ecotoxicological endpoints are covered by a more recent study using the method described in 2014/2356534 and 2016/123268. The LOQ of this more recent methods covers the derived NOEC in the mesocosm studies. The method described was state of the art in the year 1999.**

Report:	CA 4.1.2/94 [redacted] 2001 Alphacypermethrin (BAS 310 I) - Dietary toxicity (LC50) to the northern bobwhite (Colinus virginianus) AL-534-003 Report ETX-00-182
Guidelines:	EPA 71-2, EPA 850.2200, OECD 205, EEC 91/414 Annex II 8.1.2,EEC 96/12
GLP:	Yes (Department of Health of the Government oft he United Kingdom, United Kingdom)

Principle of the method HRC/FCH/M27/00 (based on SAMS 354-2):
Extraction from diet occurred with hexane (under heating), then concentration of the extracts occurred followed by dilution in the mobile phase and analysis by HPLC-UV (Zorbax ODS, 5 µm, 150 × 4.6 mm id, mobile phase: acetonitrile/aq. 0.005M ammonium formate (75/25 v/v), detection at 230 nm). External calibration.

Specificity/Interferences:	No interference was observed at the retention time of the analyte. Chromatograms were provided for control diet, reagent blank, calibration solution, fortified sample and test sample. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.
Linearity:	Five standard solutions in the concentration range from 0.5 to 2.5 µg/mL were used for the calibration (in total three calibrations). The response of the method was found to be linear in this range with a r2 = 0.99948. The resulting calibration graph was provided together with the corresponding regression equation.
Accuracy:	Fortifications occurred at different levels with alpha-cypermethrin (see Table below). Results for procedural recoveries but also for homogeneity and dose verification are given in the Table below.
Repeatability:	See Tables below
Limit of Quantification:	set at 1.125 ppm (based on signal to noise ratio)

Table 4.1.2-93: Dose verification, homogeneity and procedural recoveries

Procedural recoveries					
Matrix	**Analyte**	**Level (ppm)**	**Mean recovery (%)**	**% RSD**	**n**
Diet	Alpha-cypermethrin	156	100.5 (Day 1) 99.5 (Day 2)	0.35 (Day 1) 1.26 (Day 2)	2 6
		Overall 156 (Day 1 + Day 2)	99.7	1.16	8
		5000	99.7 (Day 1) 100.0 (Day 2)	0.5 (Day 1) 0.91 (Day 2)	2 6
		Overall 5000 (Day 1 + Day 2)			8
Dose verification					
Diet	Alpha-cypermethrin	156	100	-	2
		313	99	-	2
		625	101	-	2
		1250	100	-	2
		2500	99	-	2
		5000	99	-	2
Homogeneity					
Diet	Alpha-cypermethrin	156	98	0.96	6 (n =3×2, top, middle, bottom)
		5000	99.2	0.63	6 (n =3×2, top, middle, bottom)

Conclusion: **The method is validated according to SANCO/3029/99 rev.4. However, based on the fortification experiments, a LOQ of 156 ppm is proposed instead of the LOQ stated in the report (determined by the signal/noise approach). The method (LOQ = 156 ppm and working range of 156 – 5000 ppm) is therefore considered "fit for purpose" and covers the endpoints determined in the study (LC50 of 5000 ppm and NOEC of 625 ppm).**

Report:	CA 4.1.2/95 [redacted] 2002 CL 912554 (metabolite of BAS 310 I, Alpha-Cypermethrin): Acute toxicity study on the bluegill sunfish (Lepomis macrochirus) in a static system over 96 hours 2002/1004682

Report:	CA 4.1.2/101 N.N. Certificate of Analysis in Support of KCA 8.2.1/10 (BAS 310I) 2017/1125983
Guidelines:	not stated
GLP:	not stated

Note: This document provides a valid certificate of analysis as the one reported in study KCA 8.2.1/10 apparently showed an expiry date prior to study finalization. No data for the summary of the studies below is in this document.

Principle of the method CP 389 (HPLC-UV):
The analytical method CP 389 describes the determination of Reg. No. 130213 (metabolite 3-PBA) and Reg. No. 4080830 (DCVA) in aqueous matrices by means of HPLC. The method is based on reversed phase chromatography using a YMC J'sphere ODS-H80 4 µm. Quantification was achieved by UV detection at 212 nm and external calibration. A 2 mL aliquot of the 100 mg/L sample was transferred into a 20 mL volumetric flask. The sample was diluted with 6 mL acetonitrile, subsequently 100 µL sulfuric acid 0.5 mol/l was added. The flask was made up to the calibration mark with water. 50 µL of these solutions were injected and analysed by HPLC-UV. For analysis in OECD-medium, all samples were dissolved that the resulting solution contains 30% (v/v) acetonitrile and sulfuric acid in the concentration 500 µL/100 mL. 50 µL of these solutions were injected and analysed by HPLC-UV.

Table 4.1.2-94: Validation data for method CP389 (HPLC-UV) to determine metabolites 3-PBA and DCVA in water

Metabolite 3-PBA (CL 206128, Reg. No. 130213)				
Matrix	**LOQ**	**Linearity** **Range** **Correlation coefficient**	**Fortification levels**	**Specificity/interferences**
CA 4.1.2/96 2002/ 1004683 Tap water	Not stated. Based on the available results: 100 mg/L.	Linear in the concentration range from 0.2 to 20 mg/L (n = 5, duplicate injection). r ≥ 0.9999. The resulting calibration graph was provided but not the corresponding regression equation. The accuracy of the standard solution was checked by a separate second weight. The concentration of the prepared samples (~ 10 mg/L) meet the calibration range. The absence of matrix effects was not demonstrated.	Analysis of fortified solutions of tap water were performed. Mean recovery is presented in the Table below. RSD is also presented in the Table below and has been re-calculated based on the available results.	No interference of the matrix with the test substance could be observed under the analytical conditions used. Chromatograms have been provided for a calibration standard, control, test sample and fortified sample. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.

CA 4.1.2/98 2001/ 1014673 Water (M4-medium)	Not stated. Based on the available results: 6 mg/L seems to be achievable but not considered as fully validated (n = 3 if the overall results are considered). The level of 50 mg/L can be considered as sufficiently validated taking into account the overall results of studies KCA 8.2.1/10 and KCA 8.2.4.1/05	Linear in the concentration range from 0.2 to 20 mg/L (n = 5, duplicate injection). r ≥ 0.9999. The resulting calibration graph was provided but not the corresponding regression equation. The accuracy of the standard solution was checked by a separate second weight. The concentration of the prepared samples (~ 0.6 mg/L for the lowest fortified level and ~ 10 mg/L for the highest fortified level) meet the calibration range. The absence of matrix effects was not strictly demonstrated.	Fortifications of M4-water occurred with alpha-cypermethrin at 6 and 50.6 mg/L. Mean recovery at each fortification level is presented in the Table below. No RSD has been calculated (n = 2).	No interference of the matrix with the test substance could be observed under the analytical conditions used. Chromatograms have been provided for controls and test samples at the lowest and highest concentrations. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.
CA 4.1.2/100 2002/ 1004140 Water (OECD-medium)	Not stated.	Linear in the concentration range from 1.0 to 20 mg/L (n = 5, duplicate injection). r ≥ 0.9999. The resulting calibration graph was provided but without the corresponding regression equation. The accuracy of the standard solution was checked by a separated second weight. The absence of matrix effect was not reported.	Fortifications of OECD-medium occurred with the metabolite at 6.2 and 51.7 mg/L (see Table below). No data on RSD has been reported.	No interference could be observed. Chromatograms have been provided for control and test samples only. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.

Metabolite DCVA (CL 912554, Reg. No. 4080830)				
CA 4.1.2/95 2002/ 1004682 Tap water	Not stated. Based on the available results: 100 mg/L.	Linear in the 0.4 to 40 mg/L (n = 5, duplicate injection) r ≥ 0.9999 The resulting calibration graph was provided but not the corresponding regression equation. The accuracy of the standard solution was checked by a separate second weight. The concentration of the prepared samples (~ 10 mg/L) meet the calibration range.	Analysis of fortified solutions of tap water were performed. Mean recovery is presented in the Table below.	No interference of the matrix with the test substance could be observed under the analytical conditions used. Chromatograms have been provided for a calibration standard, control, test sample and fortified sample. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.
CA 4.1.2/97 2001/1017462 Water (M4-medium)	Not stated. Based on the available results: 6 mg/L seems to be achievable but not considered as fully validated (n = 3 if the overall results are considered). The level of 50 mg/L can be considered as sufficiently validated taking into account the overall results of studies KCA 8.2.1/08 and KCA 8.2.4.1/04.	Linear in the concentration range from 0.2 to 20 mg/L (n = 5, duplicate injection). r ≥ 0.9999. The resulting calibration graph was provided but not the corresponding regression equation. The accuracy of the standard solution was checked by a separate second weight. The concentration of the prepared samples (~ 1.2 mg/L for the lowest fortified level and ~ 10 mg/L for the highest fortified level) meet the calibration range. The absence of matrix effects was not strictly demonstrated.	Fortifications of M4-water occurred with alpha-cypermethrin at 6 and 50.4 mg/L. Mean recovery at each fortification level is presented in the Table below. No RSD has been calculated (n = 2).	No interference of the matrix with the test substance could be observed under the analytical conditions used. Chromatograms have been provided for controls and test samples at the lowest and highest concentrations. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.

CA 4.1.2/99 2002/ 1004139 Water (OECD-medium)	Not stated.	Linear in the concentration range from 1.0 to 20 mg/L (n = 5, duplicate injection). r ≥ 0.99998. The resulting calibration graph was provided but not the corresponding regression equation. The accuracy of the standard solution was checked by a separated second weight. The absence of matrix effects was not reported	Fortifications of OECD-medium occurred with the metabolite at 6 and 50 mg/L (see Table below). No data on RSD has been reported.	Absence of interference has not been demonstrated within this study. Reference was made to controls a nalysed in study 01/0418/60/2 (Study No. 37). Typical chromatograms have been provided for test samples only. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.

Metabolite not detectable in controls.
* number of replicates, each injected twice.
** Calculated based on the results obtained with the fortified (Day 0 storage) and test (Day 0) samples.

Notes:
- In tap water, analytical results of the fortified sample after storage for two days resp. four days confirm the stability of the test substance in tap water. The recoveries obtained at the end of the test remain within +/- 10% of the nominal concentration.
- In M4-medium, the analytical results of the fortified samples after storage for three days confirm the stability of the test substance in M4-water. Recoveries at the end of the test remain within +/- 10% of the nominal concentration.
- In OECD-medium, recoveries after 72hrs (end of the test) remain within the +/- 10% of the nominal concentration.

Conclusion: **Considering the results available for the fortified samples together with the results of the test samples, the method can be considered "fit for purposes". The LOQ in the various aqueous media support the derived ecotoxicological endpoints.**

Report:	CA 4.1.2/102 Jatzek H.-J., 2002 CL 206969 - Determination of the acute effect on the swimming ability of the water flea Daphnia magna STRAUS 2002/1004857
Guidelines:	EEC 92/32 A V C 2, OECD 202 Part I (1984),EPA 850.1010,ISO 6341,ISO/DIS 10706
GLP:	Yes (Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz, Germany)

The analyses were carried out as a separate study at the test facility Ecology and Environmental Analytics, BASF, DE - Concentration control analysis of REG. No. 4080665 (CL 206969-(metabolite 3-Phenoxybenzaldehyde) in water by HPLC method CP389 (ZH/TC-project01/0419/50/2)– PCP06427, Fietz G. (2001), BASF Ecology and Environmental Analytics, DE, GLP (GLP certificate dated from 1998, end of the analytical report: 2001).

Principle of the method CP390 (HPLC-UV):
The analytical method CP390 describes the determination of Reg. No. 4080665 (3-phenoxybenzaldehyde) in aqueous solutions by means of HPLC-UV. The method is based on reversed phase chromatography using a YMC J'sphere ODS-H80. Quantification was achieved by UV detection at 224 nm and external calibration. The samples were appropriately diluted with acetonitrile/water so that the final solutions had an acetonitrile content of approx. 20%. 100 µL of these solutions were injected and analysed by HPLC-UV. External calibration.
Matrix**:** water (M4-medium).

Specificity/interferences:	No interference of the matrix with the test substance could be observed under the analytical conditions used. Chromatograms have been provided for a calibration standard, control and test samples. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.
Linearity:	Five standard solutions in the concentration range from 0.08 to 10 mg/L were used for the linearity. The response of the method was found to be linear in this range with a correlation coefficient = 0.99985. The resulting calibration graph was provided together the corresponding regression equation. The accuracy of the standard solution was checked by a separate second weight. It cannot be checked if the concentration of the prepared samples meet the calibration range but it is stated that dilution occurred to meet the calibration range. The absence of matrix effects was not strictly demonstrated.
Accuracy*:*	Fortifications of M4-water occurred with the metabolite at 0.77 and 10.77 mg/L. Mean recovery at each fortification level is presented in the Table below.
Repeatability*:*	No RSD has been calculated (insufficient replicates).

Limit of Quantification: Not stated in the study report but proposed at 0.77 mg/l based on the lowest fortification level assessed.

Table 4.1.2-97: Recoveries obtained for the metabolite 3-phenoxybenzaldehyde (CL 206969) in the fortified samples of M4-water by the HPLC-UV method CP390

Fortified samples						
Analyte	**Matrix**	**Fortified level mg/L**	**% mean recovery % range**	**% mean recovery**	**% RSD**	**n***
CL 206969 (3-phenoxybenzaldehyde)	M4-water	0.77	-	86.4	-	1 × 2
		10.77	-	101.3	-	1 × 2
Test samples at test initiation						
CL 206969 (3-phenoxybenzaldehyde)	M4-water	10.0	-	74.1	-	1 × 2
		Overall (10) **	74.1 – 101.3	87.7	-	2 × 2

* at initiation only since at the end, a considerable decrease of the recoveries is obtained.
** Calculated based on the results obtained with the fortified and test (Day 0) samples.
Note: the recoveries obtained after three days of storage decreased considerably to levels as low as 5.6% at the lowest level and at non detectable
level at the highest level tested.

Conclusion: **The method allows the determination of the metabolite 3-phneoxybenzoic acid in aqueous media by HPLC-UV detection.**

Report:	CA 4.1.2/103 Fietz G., 2001 Bestimmung der Alpha-Cypermethrin Metabolite Reg.No. 4 080 830 und Reg.No. 130 213 in Wasser mittels HPLC 2001/1015123
Guidelines:	none stated
GLP:	Yes

Principle of the method CP390 (HPLC-UV):
The analytical method CP390 describes the determination of Reg. No. 4080665 (3-phenoxybenzaldehyde) and Reg.No. 130213 (DCVA) in aqueous solutions by means of HPLC-UV. The validation was done in OECD-medium as representative aqueous medium for other aqueous media.
The method is based on reversed phase chromatography using a YMC J'sphere ODS-H80. Quantification was achieved by UV detection at 224 nm and external calibration ra. The samples were appropriately diluted with acetonitrile/water so that the final solutions had an acetonitrile content of approx. 30%. Prior to injection, samples were acidified with 0.5M sulphuric acid. 100 µL of these solutions were injected and analysed by HPLC-UV. External calibration.
Matrix**:** Water (OECD-medium)

Specificity/interferences:	No interference of the matrix with the test substance could be observed under the analytical conditions used. Preparation of a blank water sample followed by analysis did not show any interferences. Chromatograms have been provided for a calibration standard, control and test samples. Identity of the analysed compound was confirmed by comparison of the mean retention time of the reference substance with the retention time of the corresponding peaks of the test item.
Linearity:	Five standard solutions in the concentration range from 0.2 to 20.0 mg/L were used. Preparation was done in in a mixture of acetonitrile/pure water/0.5 M H_2SO_4 (300/700/5 v/v/v). The response of the method was found to be linear in this range with a correlation coefficient of at least 0.9999 for both analytes. The resulting calibration graph was provided together the corresponding regression equation. The accuracy of the standard solution was checked by a separate second weight. It cannot be checked if the concentration of the prepared samples meet the calibration range but it is stated that dilution occurred to meet the calibration range. The absence of matrix effects was not strictly demonstrated.
Accuracy*:*	Fortifications of OECD-water occurred with the two metabolite at 0.4, 10.0, and 100 mg/L. Mean recovery at each fortification level is presented in the Table below. 5 replicates at each concentration level was prepared.
Repeatability*:*	RSD was below 20% for both analytes at all concentration levels.

Limit of Quantification: 0.4 mg/L for 3-PBAS as wll as for DCVA.

Table 4.1.2-98: Recoveries obtained for the metabolites 3 in the fortified samples of OECD-medium by the HPLC-UV method CP390

Fortified samples						
Analyte	**Matrix**	**Fortified level mg/L**	**% mean recovery % range**	**% mean recovery**	**% RSD**	**n***
Reg.No4080830 (3-phenoxybenzaldehyde)		0.4	99.7-100.7	100.4	0.4	5

		100.0	101.4-102	101.8	0.2	5
Reg.No. 130213 (DCVA)		0.4	97.3-99.8	98.4	1.1	5
		10.0	99.1-100.3	99.7	0.5	5
	OECD	100.0	101.7-102.4	102.2	0.3	5

Conclusion: **The method allows the determination of the metabolites 3-phneoxybenzoic acid and DCVA in aqueous media by HPLC-UV detection with a limit of quantification of 0.4 mg/L**

(g)Methods in water, buffer solutions, organic solvents and any additional matrices resulting from the physical and chemical properties tests

Where necessary, these methods are reported along with the respective studies.

Report:	CA 4.1.2/104 Bohle J. F., 1991 Alphacypermethrin (FASTAC): Development of an analytical method AL-210-004
Guidelines:	None
GLP:	No

The analytical method was used to support the results of the solubility in organic solvents determined in the study by Bohle 1991 which was considered for the first approval of alpha-cypermethrin. Description of the method and validation were however not initially reported and are presented here to be complete after the study has been submitted during the course of the assessment.

Principle of the method:
The content of alpha-cypermethrin is quantified by using a gas chromatographic (GC) procedure that employs an internal standard (octacosane). The samples are dissolved in acetone at an exactly known concentration of approx. 1 g/L and diluted with acetone/n-hexane (90:10% v/v) in order to obtain the desired concentrations. The analysis is performed on a CP-Sil 8-CB capillary column (25 m x 0.32 (I.D.) mm, d = 0.25 µm; or equivalent) with helium as carrier gas (temperature program: initial temperature 265°C, then 3°C/min, final temperature 290°C, hold 2 min). The analyte is detected using a flame ionization detector (FID).

Specificity/Interferences:	Identification by mean of retention time. Chromatograms were provided for a standard solution, blank solvent, blank containing the internal standard, samples: no interferences occurred at the retention time of the analyte.
Linearity:	The response of the GC-FID system (= peak area) to alpha-cypermethrin was demonstrated to be linear over a concentration range from 0.03 to 0.25 g/L (n = 6, each solution injected in duplicate); r = 0.9999. Samples to be analysed for determination of the solubility in organic solvents were further diluted appropriately in order to meet the calibration range.
Accuracy:	Not assessed
Repeatability:	Not assessed
Limit of Quantification:	Not stated in the study report

Table 4.1.2-99: Validation of analytical method (AL-210-004) used for the determination of the solubility in organic solvents

Analyte	Linearity, concentration range, correlation coefficient	Accuracy (Recovery) / Precision (Repeatability)	Specificity / Interference
Alpha-cypermethrin	0.03 – 0.25 g/L (n = 6, each solution injected in duplicate); correlation coefficient: r = 0.9999	Not demonstrated	Not highly specific. Identification by mean of retention time. No interferences occurred at the retention time of the analyte.

Conclusions **From the linearity data and the absence of interference, it should be expected that the method will also be accurate and precise. Therefore, the method is considered suitable for the quantification of alpha-cypermethrin in organic solvents.**

CA 4.2 Methods for post-approval control and monitoring purposes

New methods were developed to allow the separation and hence separate quantification of the diastereomeric forms of Cypermethrin in different plant and animal as well as in environmental matrices, except for air, in which quantification is limited to alpha-Cypermethrin.

(a) Methods for the analysis in food and feed of plant and animal origin

Two multiresidue methods are already peer-reviewed and are hence not again discussed in detail in this section. Both DFG S19 multiresidue methods AL-244-008 and AL-244-009 are listed in the overview Table **4.1.2-35** in CA 4.1.2. They allow the determination of alpha-Cypermethrin in grapes, wheat grain, cabbage (also addressing cabbage leaves and boiled cabbage), oilseed rape (also addressing oilseed rape press cake and refined rapeseed oil) as well as sauerkraut at a LoQ of 0.01mg/kg using GC-ECD.

Report:	CA 4.2/1 Class T.,Bendig P., 2014a Validation of the BASF analytical method L0245/01: Method for the determination of individual or combined diastereomeric forms of BAS 311 I (Cis I, Cis II (Alpha-Cypermethrin, BAS 310 I), Trans III and Trans IV) in plant matrices 2013/1361966
Guidelines:	SANCO/3029/99 rev. 4 (11 July 2000), SANCO/825/00 rev. 8.1 (16 November 2010), OECD Guidance Document on Pesticide Residue Analytical Methods (ENV/JM/MONO(2007)17 - 13-Aug-07, EPA 860.1340
GLP:	yes (certified by Landesanstalt fuer Umwelt, Messungen und Naturschutz Baden-Wuerttemberg, Karlsruhe, Germany)

Remark: The title has slightly changed compared to the one originally submitted in the application. The title as presented now in the dossier reflects the purpose of the study in a more appropriate manner. A BASF-method number was also allocated to unequivocally identify the method. The originally assigned title was “Development and Validation of an Analytical Method for the Determination of alpha-Cypermethrin (BAS 310 I) in 5 Crop Types”; however by the assigned DocID 2013/1361966 the study can be unequivocally identified.

Principle of the method

The Cis II isomer pair of Cypermethrin (= alpha-Cypermethrin) and the other 3 isomer pairs, i.e. the diastereomeric forms of BAS 311 I (Cypermethrin) are analysed using the QuEChERs multi-residue method approach with acetonitrile extraction and d-SPE clean-up.

Sample extracts were analysed by reversed-phase (RP-) liquid chromatography and tandem mass spectrometry (LC-MS/MS) and quantified using matrix-matched standards.

The LC-MS/MS method allows to quantify and to confirm the four diastereomeric forms of Cypermethrin, using two MRM transitions (common to all analytes) based on the formation of ammonium adducts (433 m/z -> 191 m/z and 435 m/z -> 193 m/z).

The limit of quantification (LOQ) of the method is ≤0.01 mg/kg per pair of enantiomers.

Recovery findings

For method validation, plant materials were fortified: Lettuce (high in water), whole orange (high in acid), wheat grain (dry, high in starch), dry bean (high in protein), and oil seed rape seed (high in oil) (5 replicates per level and crop type). Solutions containing all diastereomeric forms of Cypermethrin (i.e. Cis I/II and Trans III/IV) in appropriate ratios to obtain fortifications levels at LOQ and at 10 x LOQ were added.

Additionally, duplicate samples per crop type were kept untreated as blank controls to show that no significant chromatographic signal interference was observed. Furthermore, two samples per crop type were fortified with alpha-Cypermethrin (Cis II) only at 10 x LOQ and examined for significant conversion, e.g. the formation of the Cis I diastereomeric form.

Average recoveries for each analyte peak, for both ion transitions monitored, and for all five crop materials were within the acceptable range of 70 % to 110 % with relative standard deviations (RSD) of ≤ 20 %.
Residues and chromatographic signal interference in all blank control specimens were below 20 % of the LOQ (one exception of Cis II in grain at ≤ 0.003 mg/kg). Transformation of alpha-Cypermethrin (Cis II) e.g. to its Cis I diastereomeric form was not significant during analysis.

Matrix effects were significant (i.e. > ±20%) especially for wheat grain and oilseed rape seed were more than 20 % response enhancement was observed. Thus quantitative determination was always carried out using calibration solutions in matrix, with lambda-cyhalothrin added as internal standard.

Detailed results of recoveries for each mass transition and crop are given in Table 4.2-1. Effects of matrix on response are demonstrated in Table 4.2-2. Results of the examination of conversion of the cis II-isomer to the cis I-isomer are presented in Table 4.2-3.

Linearity

Internal calibration using matrix matched standards was used for quantitation of the analytes by LC-MS/MS. Calibration functions ranging from (approx. concentrations exemplified for Cis I and Trans III Cypermethrin) 0.40 ng/mL to 30 ng/mL for lettuce and orange, from 0.20 ng/mL to 30 ng/mL for wheat grain and dry bean and from 0.1 ng/mL to 30 ng/mL for oilseed rape seed, always with ≥ 5 concentration levels were used to evaluate the final extracts.

Linear regression equations were generated using the Analyst software with 1/x weighting, resulting in internal calibration functions with correlation coefficients r ≥ 0.99.

Specificity	The method allows the specific determination of the diastereomeric forms of BAS 311 I (Reg. No. 127266) by using two specific mass transitions for quantitation and confirmation: 433 m/z → 191 m/z and 435 m/z → 193 m/z (ammonia adduct). Residues and chromatographic signal interference in all blank control specimens were below 20 % of the LOQ (one exception of Cis II in grain at ≤ 0.003 mg/kg). Transformation of alpha-Cypermethrin (Cis II) e.g. to its Cis I diastereomeric form was not significant during analysis.
Limit of Quantitation	The method achieves an LOQ of ≤ 0.01 mg/kg per analyte. The LOD (limit of detection) is set to about ≤ 0.002 mg/kg per analyte.
Repeatability	The overall relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table 4.2-1.
Reproducibility	Reproducibility of the method was not determined within this validation study.

Stability in Solutions and Extracts

Solutions with the analytes were used throughout the study and gave consistent results and recoveries. Final sample extracts acidified with formic acid were stored prior to final LC/MS/MS analyses for several weeks refrigerated. Examination of sample extracts where only alpha-Cypermethrin (Cis II) was fortified resulted in no or very little conversion e.g. formation of the analyte to the Cis I peak after several weeks of refrigerated storage. Acceptable recoveries of all analytes in crop sample extract (acidified acetonitrile) stored refrigerated for several weeks demonstrate the stability of the analytes during refrigerated storage.

Thus, extracts and solutions are considered stable for at least 4 weeks.

Conclusion	**It was proven that the method L0245/01 is suitable to determine residues of the diastereomeric forms of BAS 311 I (Cypermethrin, Reg. No. 127266) in the 5 following crop types: lettuce (high in water), whole orange (high in acid), wheat grain (dry, high in starch), dry bean (high in protein), and oil seed rape seed (high in oil). The residue methods fulfils the registration requirements of SANCO/3029/99 rev.4, 11/07/2000; SANCO/825/00 rev. 8.1, 16/11/2010, OECD ENV/JM/MONO(2007)17, 13-Aug-2007, and EPA OPPTS 860.1340, Aug-1996.**

Remark: Assessment of the extraction efficiency of the residue method 567/1, as well as multimethods QuECHERS and DFG-S19 was accomplished within the metabolism study in lettuce, representing crop commodities of high water content. The extraction schemes were shown to give comparable extraction recoveries. Results are discussed in detail in chapter M-CA 6.2.1/1 ("Metabolism of ^{14}C-Alpha-Cypermethrin in lettuce", Schreiner D., Possienke M.).

As in due course of gathering scientific information it was deemed scientifically adequate to also assessed extraction efficiency for other crop commodities, hence an additional, separate study using unlabeled samples from field trials was conducted: "BAS 310 I (alpha-Cypermethrin): Bridging Extractability of BAS 310 I (alpha-Cypermethrin) from Barley Grain, Olive Fruit and Orange Whole Fruit using Acetonitrile/Water (4 Methods, incl. QuEChERS) or Methanol/Water/HCl (BASF Method 567/1) as Extraction Solvents"). This study is presented and described in detail in chapter MCA 4.2/11.

Report:	CA 4.2/2 Austin R., 2014a Independent laboratory validation (ILV) of the BASF analytical method L0245/01: Method for the determination of individual or combined diastereomeric forms of BAS 311 I (Cis I, Cis II [Alpha-Cypermethrin, BAS 310 I], Trans III and Trans IV) in plant matrices 2014/1145880
Guidelines:	SANCO/825/00 rev. 8.1 (16 November 2010), OECD Guidance Document on Pesticide Residue Analytical Methods (ENV/JM/MONO(2007)17 - 13-Aug-07, EPA 860.1340
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Remark: The title of 2014/1145880 has slightly changed compared to the one originally submitted in the application. The title as presented now in the dossier reflects the purpose of the study a more appropriate manner. A BASF-method number was also allocated to unequivocally identify the method. The originally assigned title was "ILV of BAS 310 I and its isomers in plant matrices"; however by the assigned DocID 2014/1145880 the study can be unequivocally identified.

Principle of the methods

BAS 311 I (Cis I, Cis II [alpha-Cypermethrin: BAS 310 I], Trans III and Trans IV) were analysed using the QuEChERs multi-residue method approach with acetonitrile extraction and d-SPE clean-up. Sample extracts were analysed by liquid chromatography and tandem mass spectrometry (LC-MS/MS) and quantified using matrix-matched standards. The LC-MS/MS method allows to quantify and to confirm the four diastereomeric forms of Cypermethrin, using two MRM transitions (common to all analytes) based on formation of ammonium adducts (433 m/z -> 191 m/z and 435 m/z -> 193 m/z). The limit of quantification (LOQ) of the method is ≤ 0.01 mg/kg per pair of enantiomers.

Recovery findings

The validation study was carried out using lettuce (high in water), orange (high in acid), wheat grain (high in starch), oil seed rape seed (high in oil) and dry bean seed (high in protein). Plant materials were fortified (5 replicates per level and crop type) with solutions containing all diastereomeric forms of Cypermethrin (i.e. Cis I/II and Trans III/IV) in appropriate ratios to obtain fortifications levels at LOQ and at 10×LOQ.

Average recoveries for each analyte peak, for both ion transitions monitored, and for all five crop materials were within the acceptable range of 70 to 120% with relative standard deviations (RSD) of ≤ 20%.

Matrix effects were significant (i.e. > ±20%) for orange, wheat grain, oilseed rape seed and dry bean seed, where greater than 20 % response suppression was observed. Thus quantitative determination was always carried out using calibration solutions in matrix, with lambda-cyhalothrin added as internal standard.

Detailed results of recoveries for each mass transition and crop are given in Table 4.2-4. Effects of matrix on response are demonstrated in Table 4.2-5.

Average matrix effect (%) = (average matrix-matched standard peak area - average solvent standard peak area) ÷ average solvent standard peak area × 100. A positive value means enhancement and a negative value means suppression of the analyte response.

Linearity	Good linearity (regression coefficients ≥ 0.999) was observed at a concentration > 0.1 ng/mL for Cis I and Trans III.
Specificity	Quantification was performed by use of highly selective LC-MS/MS detection. Two selected ion mass transitions were evaluated in order to demonstrate that the method achieves a high level of selectivity. Residues and chromatographic signal interference in all blank control specimens were below 20 % of the LOQ.
Limit of Quantification	The limit of quantification (LOQ) of the method was ≤ 0.01 mg/kg per pair of enantiomers.
Repeatability	For both ion transitions monitored, and for all five crop materials, the relative standard deviations (RSD) were always below 20%. The detailed values are shown in Table 4.2-4.
Reproducibility	In context of this ILV study, the reproducibility of the method L0245/01 was estimated. As can be seen from the results, a high reproducibility was determined.
Conclusion	**The method L0245/01 was successfully independently validated with a limit of quantification of ≤ 0.01 mg/kg per analyte (pair of enantiomers) in the 5 following crop types: Lettuce (high in water), whole orange (high in acid), wheat grain (dry, high in starch), dry bean (high in protein), and oil seed rape seed (high in oil).** **The residue method fulfils the registration requirements of SANCO/825/00 rev. 8.1, OECD ENV/JM/MONO(2007)17 and EPA OPPTS 860.1340.**

Two multiresidue methods for animal matrices are already peer-reviewed and are hence not again discussed in detail in this section. Both DFG S19 multiresidue methods AL-245-007 and AL-245-008 are listed in the overview Table 4.1.2-16 in CA 4.1.2.

A newly developed method allowing the separation to allow the separation and quantification of the diastereomeric forms of Cypermethrin in different plant and animal as well as in environmental matrices.

Report:	CA 4.2/3 Class T., Bendig P., 2014a Validation of the BASF analytical method L0231/01: Method for the determination of individual or combined diastereomeric forms of BAS 311 I (cis I, cis II (Alpha-Cypermethrin, BAS 310 I), trans III and trans IV) in animal matrices 2013/1361967
Guidelines:	SANCO/3029/99 rev. 4 (11 July 2000), SANCO/825/00 rev. 8.1 (16 November 2010), EPA 860.1340, OECD-ENV/JM/MONO/(2007)17
GLP:	yes (certified by Landesanstalt fuer Umwelt, Messungen und Naturschutz Baden-Wuerttemberg, Karlsruhe, Germany)

Remark: The title has slightly changed compared to the one originally submitted in the application. The title as presented now in the dossier reflects the purpose of the study a more appropriate manner. A BASF-method number was also allocated to unequivocally identify the method. The originally assigned title was "Validation of the BASF Analytical Method L0231/01: Method for the determination of Individual or Combined Diastereomeric Forms of BAS 311 I (Cis I, Cis II [alpha-Cypermethrin, BAS 310I], Trans III and Trans IV) in Animal Matrices"; however by the assigned docID 2013/1361967 the study can be unequivocally identified.

Principle of the method

The Cis II isomer pair of Cypermethrin (= alpha-Cypermethrin) and the other 3 isomer pairs, i.e. the diastereomeric forms of BAS 311 I, are analysed using the QuEChERs multi-residue method approach with acetonitrile extraction and d-SPE clean-up, with the exception of fat where the DFG S19 module was used for extraction (E7) and clean-up by gel permeation chromatography (GPC) for clean-up. In addition to the QuEChERS approach an acetonitrile based extraction was performed for egg and d-SPE was applied for extract clean-up.

Sample extracts were analysed by reversed-phase (RP-) liquid chromatography and tandem mass spectrometry (LC-MS/MS) and quantified using matrix-matched standards.

The LC-MS/MS method allows to quantify and to confirm the four diastereomeric forms of Cypermethrin, using two MRM transitions based on ammonium adduct ions (433 m/z -> 191 m/z and 435 m/z -> 193 m/z) for quantitation and confirmation.

The limit of quantification (LOQ) of the method is ≤0.01 mg/kg per analyte (i.e. pair of enantiomers).

Recovery findings

The analytical method L0231/01 was validated in the PTRL study no. P 2984 G. For method validation, animal materials (whole milk, eggs, bovine meat, liver, kidney and fat) were fortified with solutions containing all diastereomeric forms of Cypermethrin (i.e. Cis I/II and Trans III/IV) in appropriate ratios to obtain fortifications levels at LOQ (≤0.01 mg/kg per peak) and at 10xLOQ, each with 5 replicates per level and matrix type.

Additionally, two samples were kept untreated as blank controls to show that no significant chromatographic signal interference caused by the analytical method was observed.

Furthermore, two samples per matrix type were fortified with alpha-Cypermethrin (Cis II) only at 10xLOQ (0.1 mg/kg) and examined for significant formation of the Cis I diastereomeric form.

Average recoveries for each analyte, for both ion transitions monitored, and for all six matrix types were within the acceptable range of 70 % to 110 % with relative standard deviations (RSD) of ≤ 20 %.

Residues and chromatographic signal interference in all blank control specimens were below 20 % of the LOQ. Transformation of alpha-Cypermethrin (Cis II) to its Cis I diastereomeric form was not significant.

Matrix effects were significant (i.e. > ±20%) for all matrices except for egg (acetonitrile extracts).

Thus quantitative determination was always carried using calibration solutions in matrix, with lambda-cyhalothrin used as internal standard for all matrices except egg (acetonitrile extracts).

Detailed results of recoveries for each mass transition and matrix are given in Table 4.2-6. Effects of matrix on response are demonstrated in Table 4.2-7. Results of the examination of conversion of the cis II-isomer to the cis I-isomer are presented in Table 4.2-8.

Linearity

Linear regression equations were generated using the Analyst software with 1/x weighting, resulting in internal calibration functions with correlation coefficients r ≥ 0.99.

Internal calibration was used for quantitation of the analytes by LC-MS/MS using the QuEChERS and DFG S19 approach. External calibration was used for the acetonitrile extraction of egg. Calibration functions were established with matrix matched standards. Calibration functions ranging from 0.20 ng/mL to 30 ng/mL for whole milk, bovine meat, kidney, liver, from 0.20 ng/mL to 20 ng/mL for fat, from 0.10 ng/mL to 30 ng/mL for egg (QuEChERS) and from 0.10 ng/mL to 5.0 ng/mL for egg (acetonitrile extraction), using ≥ 5 concentration levels, were used to evaluate the final extracts.

Specificity

The method allows the specific determination of the diastereomeric forms of BAS 311 I (Reg. No. 127266) by using two specific mass transitions for quantitation and confirmation: 433 m/z → 191 m/z and 435 m/z → 193 m/z (ammonia adduct). Apparent residues or interferences in blank control specimens were below 20 % of the LOQ. Transformation of alpha-Cypermethrin (Cis II) to its Cis I diastereomeric form was not significant.

Limit of Quantitation

The method achieves an LOQ of ≤0.01 mg/kg per analyte. The LOD (limit of detection) is set to ≤0.002 mg/kg per analyte.

Repeatability

The overall relative standard deviations (RSD, %) for all fortification levels were ≤ 20%. The detailed values are shown in Table 4.2-6.

Reproducibility

Reproducibility of the method was not determined within this validation study.

Stability in Solutions and Extracts

Solutions with the analytes were used throughout the study and gave consistent results and recoveries. Final sample extracts acidified with formic acid were stored prior to final LC/MS/MS analyses for several weeks refrigerated. Acetonitrile extracts of egg were stable for at least 15 days when stored refrigerated.

Examination of sample extracts where only alpha-Cypermethrin (Cis II) was fortified after several weeks of refrigerated storage by LC-MS/MS resulted in no or very little formation of the Cis I peak.

Acceptable recoveries of the analytes in sample extracts demonstrate thus the stability during refrigerated storage.

Conclusion	**It was proven that the method L0231/01 is suitable to determine residues of the diastereomeric forms of BAS 311 I (Cypermethrin, Reg. No. 127266) in in various animal types: Milk, egg, bovine meat, kidney, liver and fat. The residue methods fulfils the registration requirements of SANCO/3029/99 rev.4, 11/07/2000; SANCO/825/00 rev. 8.1, 16/11/2010, OECD ENV/JM/MONO(2007)17, 13-Aug-2007, and EPA OPPTS 860.1340, Aug-1996.**

Report:	CA 4.2/4 Schernikau N., 2014a Independent laboratory validation of the BASF analytical method L0231/01: Determination of individual or combined diastereomeric forms of BAS 311 I (Cis I, Cis II (Alpha-Cypermethrin, BAS 310 I), trans III and trans IV) in animal matrices 2014/1145882
Guidelines:	EC 1107/2009 of the European Parliament and of the Council of 21 Oct 2009, SANCO/3029/99 rev. 4 (11 July 2000), SANCO/825/00 rev. 8.1 (16 November 2010), OECD-ENV/JM/MONO/(2007)17, EPA 860.1340
GLP:	yes (certified by Freie und Hansestadt Hamburg, Behoerde fuer Soziales, Familie, Gesundheit und Verbraucherschutz, Hamburg, Germany)

Remark: The title has slightly changed compared to the one originally submitted in the application. The title as presented now in the dossier reflects the purpose of the study a more appropriate manner. A BASF-method number was also allocated to unequivocally identify the method. The originally assigned title was “Independent Laboratory Validation of BAS 310 I and Isomers in Animal Matrices”; however, by the assigned DocID 2014/1145882 the study can be unequivocally identified.

Principle of the method

The objective of the study was to independently validate BASF method L0231/01 (PTRL validation study P 2984, see MCA 4.2/3) for the determination of individual or combined diastereomeric forms of BAS 311 I (cis I, cis II [alpha-Cypermethrin, BAS 310I], trans III and trans IV) in matrices of animal origin.

Samples of milk, meat, liver, kidney and egg were extracted with acetonitrile after addition of water. After addition of a buffer salt mixture, containing magnesium sulphate, sodium chloride and sodium citrate, the extract was shaken. After centrifugation, an aliquot of the acetonitrile phase was cleaned by dispersive solid phase extraction, using primary secondary amine (PSA). Additionally, samples of egg were extracted with acetonitrile without addition of water and buffer salt mixture. Samples of fat were dissolved in cyclohexane/ethylacetate and cleaned over GPC. Quantification was performed by use of highly selective LC-MS/MS detection. Two selected ion mass transitions were evaluated in order to demonstrate that the method achieves a high level of selectivity. Quantification was performed by using the linear regression with 1/x weighting and internal standards (λ-cyhalothrin).

Recovery findings

The samples were fortified with solutions containing all diastereomeric forms of Cypermethrin (i.e. Cis I/II and Trans III/IV) in appropriate ratios to obtain fortification levels at LOQ (≤ 0.01 mg/kg per isomer) and at 10xLOQ. All mean recovery values at fortification levels of 0.01 mg/kg and 0.1 mg/kg for both ion mass transitions were within the acceptable range of 70 - 120%.
The effect of all matrices on the LC-MS/MS response was assessed by comparing peak areas of matrix-matched standards with solvent standards at equivalent concentrations (at LOQ, 10xLOQ). Matrix effects on the detection of Cypermethrin isomers in extracts of all matrices were found to be significant (> 20 %). Therefore, matrix-matched standards were used for calibration for all matrices.

Detailed results of recoveries for each mass transition and matrix are given in Table 4.2-9. Matrix effects are demonstrated in Table 4.2-10.

Linearity	The linearity of the detector response of Cypermethrin isomers in matrix were demonstrated by single determination of matrix-matched calibration standards at at least seven (7) concentration levels ranging from 0.2 ng/mL to 30 ng/mL for Cis I and Trans III (Cis II and Trans IV in the given ratios). The calibration curves obtained for both ion mass transitions in all matrices were linear with coefficients of determination (r^2) greater than 0.99. The linearity of the detector response of Cypermethrin isomers in egg was demonstrated by single determination of matrix-matched calibration standards at eight (8) concentration levels ranging from 0.1 ng/mL to 20 ng/mL for Cis I and Trans III (Cis II and Trans IV in the given ratios). The calibration curves obtained for both ion mass transitions in egg were linear with coefficients of determination (r^2) greater than 0.99. The linearity of the detector response of Cypermethrin isomers in egg without water was demonstrated by single determination of matrix-matched calibration standards at eight (8) concentration levels ranging from 0.05 ng/mL to 10 ng/mL for Cis I and Trans III (Cis II and Trans IV in the given ratios). The calibration curves obtained for both ion mass transitions in egg were linear with coefficients of determination (r^2) greater than 0.99. Linear regression was performed with 1/x weighting.
Specificity	Quantification was performed by use of highly selective LC-MS/MS detection. Two selected ion mass transitions were evaluated in order to demonstrate that the method achieves a high level of selectivity. No significant interference above 30 % of LOQ was detected in any of the control specimen extracts of each matrix, so that a high level of selectivity was demonstrated.
Limit of Quantitation	The limit of quantification is ≤ 0.01 mg/kg per isomer in all matrices.
Repeatability	The overall relative standard deviations (RSD, %) for all fortification levels were ≤ 20%. The detailed values are shown Table 4.2-9.
Reproducibility	In context of this ILV study, the reproducibility of the method L0231/01 was estimated. As can be seen from the results, a high reproducibility was determined.
Conclusion	**The method was found to be valid according to the guidance documents SANCO/3029/99 rev. 4 and SANCO/825/00 rev. 8.1 for the determination of Cypermethrin isomers in milk, meat, liver, kidney, egg and fat with a LOQ of ≤ 0.01 mg/kg for Cis I and Trans III (Cis II and Trans IV in the given ratios).**

Report:	CA 4.2/5 [redacted] 2014a Investigation of the extractability of BAS 310 I in samples from animal metabolism studies based on method L0231/01 2014/1145878
Guidelines:	OECD Test Guideline 503 - Metabolism in livestock, SANCO/825/00 rev. 8.1 (16 November 2010), OECD-ENV/JM/MONO/(2007)17
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

Selected samples from hen (BASF DocID 2014/1140293, see M-CA 6.2) and goat (BASF DocID 2014/1083330, see M-CA 6.2) metabolism studies performed with radiolabelled BAS 310 I were extracted with extraction method L0231/01, which is based on the QuEChERS multimethod and the DFG S19 E6 method. All extraction procedures were compared to the extractions used in the animal metabolism studies, except for the 'hen egg yolk' extraction with acetonitrile (method L0231/01), since it is similar to the extraction procedure used in the animal metabolism study.

L0231/01 - Extraction Procedure Based on QuEChERS Multimethod:

For the extraction of muscle, egg yolk and milk matrices:

Aliquots of the homogenized samples (5 g for muscle and milk, 2.5 g for egg yolk) were extracted once with an extraction mixture (5 mL water for muscle and milk / 8 mL water for egg yolk and 10 mL acetonitrile) by vigorous shaking. Subsequently, a blend of buffer salts was added ($MgSO_4$, NaCl, disodium citrate and trisodium citrate). The mixture was shaken strongly and centrifuged. The supernatant was cleaned up using a dispersive SPE tube (Agilent) and concentrated. The residue was redissolved in a mixture of acetonitrile, water and Triton X-100 (for muscle and milk 300/280/20, v/v/v; for egg yolk 600/280/20, v/v/v). For each matrix, one replicate per extraction was generated.

L0231/01 - Extraction Procedure Based DFG S19 E6 Method (fat matrices):

For the extraction of fat matrices:

5 g of the homogenized sample were supplemented with 50 mL cyclohexane/ethyl acetate (1/1, v/v). The emulsion was decanted over cotton wool and again supplemented with 50 mL cyclohexane/ethyl acetate (1/1, v/v). Thereafter, the sample was concentrated and redissolved in 35 mL isohexane. The sample was partitioned four times using a separating funnel, each time with 30 mL acetonitrile. The pooled acetonitrile phase was subsequently concentrated and redissolved in a mixture of acetonitrile, water and Triton X-100 (approximate ratio of 9/6/1, v/v/v).

The extracts were analysed by LSC and ^{14}C-BAS 310 I was quantified by HPLC method LC01 (identical to method LC02 from the goat metabolism study). The identification of BAS 310 I was based on retention time comparison of the ^{14}C signals of the quantitative HPLC analyses with those of the application solution used in a reference metabolism study.

The extraction efficiency was calculated as percentage of the mg/kg values obtained from the extractions in the reference metabolism studies. For the calculation of general extractability of radioactive residues, the LSC measurements of unconcentrated extracts have been used.

Limit of Quantification

The validated LOQ of the extraction method L0231/01 is 0.01 mg/kg per analyte.

Extractability

The extractability of the matrix muscle with method L0231/01 (QuEChERS based part) was 47.4 % TRR for hen and 75.7 % TRR for goat. In fat, 87.9 % TRR (hen) and 96.9 % TRR (goat) were extracted with method L0231/01 (DFG S19 E6 based part). The extraction of milk with method L0231/01 (QuEChERS based part) resulted in 59.0 % TRR. Egg yolk was extracted with method L0231/01 (QuEChERS based part), whereby the extractability was low and accounted for 27.8 % TRR.

Compared with the reference metabolism studies, the extractabilities of the tested extraction protocol were comparable for goat muscle, hen fat and goat fat and ranged from 78.6 % to 95.1 % of the metabolism studies extractions. For hen muscle and goat milk, the extractabilities were somewhat lower and ranged from 63.3 % to 69.2 % Met. The extractability of egg yolk was significantly lower and accounted for 34.7 % of the metabolism study extractions.

Detailed data of the extractability of radioactive residues with the extraction methods from the reference metabolism studies are summarized in Table 4.2-11.

HPLC Results for Extracts of Animal Matrices

Muscle Extracts: In the hen muscle extract, 0.006 mg/kg of BAS 310 I (33.7 % TRR) were identified and in the goat muscle extract, 0.019 mg/kg of BAS 310 I (64.9 % TRR) were identified. The amount of BAS 310 I in goat muscle is identical to the amount of BAS 310 I, which was identified in the reference metabolism study (100.0 % of the metabolism study extractions). For hen muscle, the amount of BAS 310 I is higher in this study (150.0% of the metabolism study extractions). The relative increase of BAS 310 I in hen muscle in this study might be due to the low absolute amount of BAS 310 I.

Fat Extracts: The extraction of fat matrices resulted in 0.044 mg/kg (52.2 % TRR, hen fat) and 0.084 mg/kg (59.5 % TRR, goat fat) of BAS 310 I. The extractability of BAS 310 I was comparable to the extractabilities of the reference metabolism studies (115.8 % Met for hen fat and 65.1 % Met for goat fat).

Milk Extracts: The extraction of the matrix milk yielded 0.033 mg/kg (61.3 % TRR) of BAS 310 I. The extractability of BAS 310 I was comparable with the reference metabolism study (76.7 %).

Egg Yolk Extracts: In the extract of egg yolk (QuEChERS based part), 0.027 mg/kg of BAS 310 I (18.0 % TRR) were identified. Compared with the HPLC results of the reference metabolism study, lower amounts of BAS 310 I were extracted (52.9 % of the metabolism study extractions).

The HPLC results of the extracts of animal matrices and the HPLC results of the extracts of the reference metabolism studies are summarized in Table 4.2-11.

% Met = Extraction efficiency compared to the extraction method used in the respective metabolism study
n.a. = not applicable

Conclusion

Generally, the extractabilities in this study were comparable to the extractabilities of the reference metabolism studies (63.3-95.1 % Met); only for hen egg yolk (QuEChERS based part, 34.7 % Met) the relative extractability was lower.

For all investigated matrices and extraction methods of this study, the amount of BAS 310 I was comparable to the results of the reference metabolism studies (76.7 to 125.0 % of the metabolism studies extractions). Only for hen egg yolk (QuEChERS based part), the relative extractability was somewhat lower (52.9 % of the metabolism studies extractions).

However, for the acetonitrile based extraction of eggs in L0231/01 an identical extraction efficiency can be assumed in comparison to the reference metabolism study, since the majority of BAS 310 I was determined to be in the acetonitrile fraction in the metabolism study (~100 % Met).

Report:	CA 4.2/6 [redacted] 2014b Investigation of the extractability of BAS 310 I in samples from animal metabolism studies 2014/1145877
Guidelines:	OECD Test Guideline 503 - Metabolism in livestock, SANCO/825/00 rev. 8.1 (16 November 2010), OECD-ENV/JM/MONO/(2007)17
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Principle of the methods

Selected samples from hen (BASF DocID 2014/1140293, see M-CA 6.2) and goat (BASF DocID 2014/1083330, see M-CA 6.2) metabolism studies performed with radiolabeled BAS 310 I were extracted. Three different extraction procedures designed for the determination of BAS 310 I were tested, which are based on the residue methods SAMS 461-1 (AL-245-001), SAMS 456-1 (AL-245-003) and DFG S19 (AL-245-007). All extraction procedures were compared to the extractions used in the animal metabolism studies.

Method 1 - SAMS 461-1 (AL-245-001):

Aliquots of the homogenized samples were mixed with Na_2SO_4 in an approximate ratio of 1/2 (w/w) in case of the matrix fat or 1/12 (w/w) in case of the matrix muscle. The sample/salt mixture was extracted by boiling in acetone/isohexane (1/2, v/v) in an approximate ratio of 1/10 (sample/solvents, w/v). The extraction procedure was performed three times. The supernatants were decanted over cotton wool, pooled and made up to an adequate volume with isohexane. The extracts were concentrated and redissolved in isohexane. The samples were partitioned with acetonitrile in a separating funnel. The acetonitrile supernatants were pooled, concentrated and redissolved in a mixture of acetonitrile/water/Triton X-100 (approximately 1150/650/30, v/v/v) in case of the matrix fat and water/acetonitrile/Triton X-100 (690/300/10, v/v/v) in the case of the matrix muscle.

Method 2 - SAMS 456-1 (AL-245-003):

The homogenized milk sample was consecutively mixed with a 5 % solution of aqueous potassium oxalate, ethanol, diethyl ether and isohexane in a ratio of 10/1/10/20/10 (v/v/v/v/v). The supernatant was concentrated, made up with isohexane to an adequate volume and partitioned with acetonitrile in a separating funnel. The acetonitrile supernatants were pooled, concentrated and redissolved in a mixture of water/acetonitrile/Triton X-100 (680/300/20, v/v/v).

Method 3 - DFG S19 (AL-245-007):

Prior to extraction, 25.0 g of the sample were mixed with an adequate amount of water to result in an approximate ratio of water/acetone 1/2 (v/v) after the addition of acetone in the subsequent extraction step. After the addition of water, the mixture was homogenized using a Polytron. A volume of 100 mL acetone (final water/acetone ratio 1/2, v/v) and 17.5 g NaCl were added and the mixture was homogenized again. Thereafter, 50 mL ethyl acetate/cyclohexane (1/1, v/v) were added and the mixture was again homogenized. The homogenate was centrifuged, decanted over cotton wool and partitioned in a separating funnel (organic phase/ aqueous phase). The organic phase was made up with acetone to an adequate volume. The extract was concentrated, redissolved in isohexane and partitioned with acetonitrile in a separating funnel. In case of the matrix egg yolk, the acetonitrile supernatants were pooled, concentrated and redissolved in a mixture of water/acetonitrile/Triton X-100 (700/700/50, v/v/v).

The sample was centrifuged prior to measurement. In case of the matrix milk, the acetonitrile supernatants were redissolved in a mixture of water/acetonitrile/Triton X-100 (680/600/20, v/v/v) after the concentration step.

The extracts were analysed by LSC and ^{14}C-BAS 310 I was quantified by HPLC method LC01 (identical to HPLC method LC02 from goat metabolism study). The identification of BAS 310 I was based on retention time comparison of the ^{14}C signals of the quantitative HPLC analyses with those of the application solution used in a reference metabolism study

Limit of Quantification

The validated LOQs of the extraction methods SAMS 461-1 and SAMS 456-1 are 0.05 mg/kg and 0.01 mg/kg, respectively; the method based on DFG S19 was developed with an LOQ of 0.01 mg/kg

Extractability

The extractability of the matrix muscle with extraction method 1 was 55.7 % TRR for hen and 69.2 % TRR for goat. In fat, 88.9 % TRR (hen) and 98.7 % TRR (goat) were extracted with extraction method 1. Milk was extracted with methods 2 and 3 resulting in 94.3 % TRR and 90.7 % TRR, respectively. Egg yolk was extracted with method 3, whereby the extractability accounted for 73.0 % TRR.

Compared with the reference metabolism studies, the extractabilities of the tested extraction protocols were comparable for all matrices and ranged from 71.4 % to 102.0 % of the metabolism studies extractions.

Detailed data of the extractability of radioactive residues with the extraction methods from the reference metabolism studies are summarized in Table 4.2-12.

HPLC Results for Extracts of Animal Matrices

Muscle Extracts: In the hen muscle extract, 0.006 mg/kg of BAS 310 I (30.9 % TRR) were identified and in the goat muscle extract, 0.015 mg/kg of BAS 310 I (50.2 % TRR) were identified. The amount of BAS 310 I in hen and goat muscle was comparable to the amount of BAS 310 I in the reference metabolism studies. For goat muscle, 78.9 % of the metabolism studies extractions were identified and for hen muscle, 150.0 % of the metabolism studies extractions were identified. The relative increase of BAS 310 I observed in hen muscle might be due to the low absolute amounts of BAS 310 I.

Fat Extracts: The extraction of fat matrices with method 1 resulted in 0.053 mg/kg (63.2 % TRR, hen fat) and 0.120 mg/kg (85.2 % TRR, goat fat) of BAS 310 I. The extractability of BAS 310 I was comparable to the extractabilities of the reference metabolism studies (139.5 % Met for hen and 93.0 % Met for goat).

Milk Extracts: The extraction of the matrix milk with methods 2 and 3 yielded 0.041 mg/kg (76.8 % TRR) and 0.037 mg/kg (69.4 % TRR) of BAS 310 I. The extractability of BAS 310 I was comparable with the reference metabolism study (95.3 % for extraction method 2 and 86.0 % for extraction method 3).

Egg Yolk Extracts: In the extract of egg yolk (method 3), 0.034 mg/kg of BAS 310 I (22.8 % TRR) were identified. Although the overall extractability of the radiolabelled material was significantly lower, the amount of freely extractable BAS 310 I was largely comparable (66.7 % of the metabolism study extractions).

The HPLC results of the extracts of animal matrices and the HPLC results of the extracts of the reference metabolism studies are summarized in Table 4.2-12.

(b) Methods for the analysis in soil and water

Analytical methods for the determination of alpha-Cypermethrin and its relevant metabolites for post-approval and monitoring purposes in soil are identical to the ones validated for pre-registration purposes. Respective methods are described in detail in document M, chapter 4.1.2; hence they are not described again in detail in this chapter.

The newly developed method for the determination of the diastereomeric forms of Cypermethrin and its metabolites as well as its ILV is summarised below.

Report:	CA 4.2/7 Andrews, R.S., 2014a Validation of Method D1413/01 (L0258/01): Method for the Determination of the Diastereomers of BAS 311 I and Metabolites 3-Phenoxybenzoic acid (Reg. No. 130213), DCVA (Cis and Trans Isomers, Reg. No. 180011) and 3-Phenoxybenzaldehyde (Reg. No. 4080665) in Water by LC-MS/MS 2014/7002180
Guidelines:	OPPTS 850.7100, OPPTS 835.6100, PR Notice 2011-3, SANCO/3029/99 rev. 4 (11 July 2000, pre-registration residue methods) SANCO/825/00 rev. 8.1(16 November 2010, post-registration residue methods) OCSPP 850.6100: Environmental Chemistry Methods and Associated Independent Laboratory Validation
GLP:	yes

Remark: The title has slightly changed compared to the one originally submitted in the application. The title as presented now in the dossier reflects the purpose of the study a more appropriate manner as analysis addressed all four isomers; hence BAS 311 was used in the updated study title. The originally assigned title was "Validation of Method D1413/01 (L0258/01): Method for the Determination of the Diastereomers of BAS 310 I and Metabolites 3-Phenoxybenzoic acid (Reg. No. 130213), DCVA (Cis and Trans Isomers, Reg. No. 180011) and 3-Phenoxybenzaldehyde (Reg. No. 4080665) in Water by LC-MS/MS", however by the assigned DocID 2014/7002180, the study can be unequivocally identified.

Principle of the method

Cypermethrin (BAS 311 I) and the four isomers of Cypermethrin (cis I, cis II, trans III, trans IV):

Using BASF Analytical Method No. D1413/01 (L0258/01), residues of parent Cypermethrin in water samples (500 mL each) are acidified and then cleaned-up and concentrated on an Oasis® HLB solid phase extraction (SPE) column eluted with acetonitrile followed by dichloromethane. The residues in the eluent are evaporated to dryness, re-dissolved in acidified acetonitrile:water (50:50, v/v), and then determined by high performance liquid chromatography (HPLC) with detection using positive electrospray ionization tandem mass spectrometry (MS/MS-ESI), monitoring at m/z 433→191 (proposed as the primary transition for quantitation) and m/z 435→193 (typically used for confirmatory purposes) for each of the four isomers. The isomers are separated by their retention times on the HPLC column, enabling quantitation of the contribution of each analyte. The limit of quantitation (LOQ) of the method is 0.75 ng/L for parent Cypermethrin and the four isomers in water.

The metabolites in water are extracted and determined in two additional, separate analyses:

DCVA (cis and trans) and PBA:

DCVA and PBA residues in water samples (60 mL each) are acidified and partitioned by shaking with ethyl acetate:cyclohexane (40:60, v/v). Residues in the organic layer are evaporated to dryness, re-dissolved and diluted with ethyl acetate and acidified water, and then concentrated to an aqueous remainder. The residues are then diluted to a final volume of acidified methanol:water (20:80, v/v) and analyzed by HPLC/MS/MS, monitoring in the negative mode ion transitions at m/z 213→93 (quantitation) and m/z 213→169 (confirmation) for PBA. The determination of DCVA is conducted without any fragmentation of the parent ion, due to the nature of the ionization, monitoring at m/z 207 or 209 in the negative mode for both isomers, which are separated by retention time and quantitated as separate species. An alternate chromatographic method is used for DCVA for confirmatory purposes. The limit of quantitation (LOQ) of the method is 50 ng/L for DCVA (cis and trans) and PBA in water.

POAL:

POAL residues in water samples (100 mL each) are acidified, and then cleaned-up and concentrated on a styrene-divinylbenzene polymeric (SDB-L) SPE column eluted with acetonitrile. The residues are then diluted to a final volume of acetonitrile:water (50:50, v/v) and determined by HPLC/MS/MS monitoring ion transitions at m/z 199→171 (for quantitation) and m/z 199→65 (for confirmation) in the negative mode. The limit of quantitation (LOQ) of the method is 50 ng/L for POAL in water.

All results are calculated by direct comparison of the sample peak responses to those of external standards.

Recovery findings

Method L0258/01 was proved to be suitable to determine residues of Cypermethrin (cis I, cis II, trans III, trans IV) and its metabolites PBA, DCVA (cis and trans) and POAL to the respective limit of quantification in drinking and surface water.

Mean recoveries of Cypermethrin residues (cis I, cis II, trans III, trans IV) from drinking and surface water samples fortified with each isomer at 0.75 ng/L and 7.5 ng/L ranged from 77 to 109% (relative standard deviation, ≤20%), considering results obtained using both the primary and secondary ion transitions.

Mean recoveries of PBA residues from drinking and surface water samples fortified at 50 ng/L and 500 ng/L ranged from 94 to 109% (RSD, ≤13%) for both the primary and secondary ion transitions.

Mean recoveries of residues of cis- and trans-DCVA from drinking and surface water samples fortified with each isomer at 50 ng/L and 500 ng/L ranged from 74 to 110% (RSD, ≤16%), considering results obtained using both the primary and secondary ion.

Mean recoveries of residues of POAL from drinking and surface water samples fortified at 50 ng/L and 500 ng/L were in the acceptable range (actual 73 to 92%, RSD ≤12%) for both transitions, except for surface water at the limit of quantitation (50 ng/L), where mean recoveries were 57% (RSD 8%) and 60% (RSD 10%), monitoring at the primary and secondary ion transition, respectively. Although on the margins of the acceptable range, the results were consistent, with low relative standard deviations; therefore, the data obtained are considered of acceptable accuracy and precision for this metabolite.

The detailed results are given in Table 4.2-13.

Linearity

Acceptable linearity was observed for the standard range and the two mass transitions tested for each analyte: The method-detector response was linear over the nominal 0.25-0.5 ng/mL range (r = ≥0.9949) for Cypermethrin (each isomer), the 0.6-10 ng/mL range (r = ≥0.9920) for DCVA (each isomer) and PBA, and the 0.08-2.0 ng/mL range (r = ≥0.9980) for POAL.

Specificity

The method successfully determines residues of Cypermethrin in water by LC-MS/MS. This was demonstrated on the basis of two different water types (surface water and drinking water). No interfering peaks were found at the retention times for these analytes, or if they were encountered, as with DCVA, the interferences were resolved using the available alternate (optional) chromatography methods. The experiment to evaluate any potential matrix effects showed that the matrix load in the samples from the each water type had no significant influence on analysis (matrix effects < 20%); therefore, the validation samples were analyzed using solvent-based calibration standard solutions.

Limit of Quantification

The method has a limit of quantification of 0.75 ng/L for parent Cypermethrin (for each of the four isomers) and 50 ng/L for the metabolites DCVA (cis and trans), PBA and POAL.

Repeatability

The relative standard deviations (RSD, %) for all fortification levels were ≤ 20%.

Stability in Solutions and Extracts

The substance solutions and final sample extracts were stored in a refrigerator and were used within the time period of stability. The stability of POAL was not tested in the final volume solution of acetonitrile:water (1:1, v/v) due to an oversight.

Conclusion

It was demonstrated that BASF Analytical Method No. D1413/01 (L0258/01) fulfils the requirements with regard to specificity, repeatability, limit of quantification, and recoveries and is, therefore, applicable to correctly determine residues of the Cypermethrin in drinking (well) water and surface (pond) water.

Report:	CA 4.2/8 Perez S., Perez R., Adams J, 2015 Independent Laboratory Validation of Method D1413: Method for the Determination of Diasteromers of BAS 311 I and Metabolites 3-Phenoxybenzoic acid (Reg. No. 130213), DCVA (Cis and Trans Isomers, Reg. No. 180011) and 3-Phenoxybenzaldehyde (Reg. No. 4080665) in Water by LC-MS/MS. 2014/7002181
Guidelines:	OCSSP 860.6100, SANCO/825/00 rev 8.1 (Nov.16, 2010), SANCO/3029/99 rev. 4 (11/07/00), SANCO/10684/2009, ENV/JMONO (2007)17
GLP:	yes

Remark: The title has slightly changed compared to the one originally submitted in the application. The title as presented now in the dossier reflects the purpose of the study a more appropriate manner as analysis addressed all four isomers; hence BAS 311 was used in the updated study title. The originally assigned title was "Independent Laboratory Validation of Method D1413/01 (L0258/01): Method for the Determination of the Diastereomers of BAS 310 I and Metabolites 3-Phenoxybenzoic acid (Reg. No. 130213), DCVA (Cis and Trans Isomers, Reg. No. 180011) and 3-Phenoxybenzaldehyde (Reg. No. 4080665) in Water by LC-MS/MS", however by the assigned DocID 2014/70021801 the study can be unequivocally identified.

The presented OECD-summary of the study is based on under GLP audited data presented in a fully audited draft report. However, as the report was not finalized at time of submission of the electronic version of the dossier, a copy of the original, signed final report of the study will be submitted upon availability, which is estimated to be early February.

Principle of the method

For the analysis of BAS 311 I (Cypermethrin) isomers Cis I, Cis II, Trans III, and Trans IV, a sample aliquot (500 mL) is concentrated on an Oasis HLB® SPE column. The eluent is concentrated to dryness and reconstituted for analysis by LC-MS/MS.

For the analysis of DCVA (*cis* and *trans*) and 3-PBA, a sample aliquot (60 mL) is extracted with a mixture of cyclohexane:ethyl acetate using a liquid–liquid partition. The organic partition is evaporated in the presence of an aqueous keeper and diluted for analysis by LC-MS/MS.

Method D (utilizing an Xbridge PFP column) of the analytical method serves as an alternative chromatographic technique for the analysis of DCVA in the case that chromatographic interferences prevents the use of Method B (utilizing an Xbridge phenyl column).

The validation trials for drinking and surface water were run using Method B with the phenyl column; however, low recoveries were obtained for cis-DCVA in surface water. The validation trials for surface and drinking water were injected a second time using the alternative chromatographic technique described in Method D with the PFP column and obtained good results.

For the analysis of POAL, a sample aliquot (100 mL) is concentrated onto a polymeric SDB-L column. The eluent is diluted for analysis by LC-MS/MS.

Recovery findings

Method D1413/01 (L0258/01) was proved to be suitable to determine residues of Cypermethrin (cis I, cis II, trans III, trans IV) and its metabolites 3-PBA, DCVA (cis and trans) and POAL to the respective limit of quantification in drinking and surface water.

Mean recoveries of Cypermethrin residues (cis I, cis II, trans III, trans IV) from drinking and surface water samples fortified with each isomer at 0.75 ng/L and 7.5 ng/L ranged in total from 51 to 126% (relative standard deviations per analyte and transition were always ≤20%; except for trans III cypermethrin (2^{nd} transition), trans IV cypermethrin (1^{st} + 2^{nd} transition) in surface water, for which RSDs of slightly above 20% were determined), considering results obtained using both the primary and secondary ion transitions.

Mean recoveries of 3-PBA residues from drinking and surface water samples fortified at 50 ng/L and 500 ng/L ranged from 65 to 113% (RSD, ≤14%) for both the primary and secondary ion transitions.

Mean recoveries of residues of cis- and trans-DCVA from drinking and surface water samples fortified with each isomer at 50 ng/L and 500 ng/L (Method B and D) ranged from 47 to 243% (RSD, ≤47%), considering results obtained using both the primary and secondary ion.

Mean recoveries of residues of POAL from drinking and surface water samples fortified at 50 ng/L and 500 ng/L ranged from 80 to 114% (RSD, ≤10%), considering results obtained using both the primary and secondary ion.

The detailed results are given in Table 4.2-14.

			5	500	85	3.6

Statistical calculations in this table are based on unrounded values; therefore, slight differences may be noted in calculations performed using rounded numbers.

Linearity

Good linearity ($r > 0.99$) was observed in the range of 0.0005 to 0.0200 ng injected in the standard solutions for Cypermethrin isomers (Cis I/II and Trans III/IV) for all mass transitions analyzed.

Good linearity ($r > 0.99$) was observed in the range of 0.0180 to 0.3000 ng injected in the standard solutions for DCVA cis/trans mixture and 3-PBA for all mass transitions analyzed.

Good linearity ($r > 0.99$) was observed in the range of 0.0048 to 0.1200 ng injected in the standard solutions for POAL for all mass transitions analyzed.

Specificity

The method determines residues of Cypermethrin, DCVA, 3-PBA and POAL. No interfering peaks were found at the retention times of the analyte. The use of matrix-matched standards was not necessary.

Limit of Quantification

The method has a limit of quantification of 0.75 ng/L for parent Cypermethrin (for each of the four isomers) and 50 ng/L for the metabolites DCVA (cis and trans), 3-PBA and POAL.

Repeatability

The relative standard deviations (RSD, %) for all fortification levels were mostly ≤ 20%. For some fortification series RSDs slightly above 20% were determined.

Reproducibility

In context of this ILV study, the reproducibility of this analytical method was estimated. As can be seen from the results, a high reproducibility was determined.

Conclusion

The method D1413/01 (L0258/01) for the analysis of Cypermethrin (cis I, cis II, trans III, trans IV) and its metabolites 3-PBA, DCVA (cis and trans) and POAL) in surface water and drinking water used LC-MS/MS for final determination, with limit of quantification of 0.75 ng/L for parent Cypermethrin (for each of the four isomers) and 50 ng/L for the metabolites DCVA (cis and trans), 3-PBA and POAL.
It was demonstrated that BASF Analytical Method No. D1413/01 (L0258/01) fulfils the requirements with regard to specificity, repeatability, limit of quantification, and recoveries and is, therefore, applicable to correctly determine residues of the Cypermethrin in drinking (well) water and surface (pond) water.

(c) Methods for the analysis in air

Report:	CA 4.2/9 Bendig P., Class T., 2013a Development and validation of an analytical method for the determination of Alpha-Cypermethrin (BAS 310 I) in air 2013/1281809
Guidelines:	SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

The objective of this study was to validate an analytical method for the determination of alpha-Cypermethrin in air (warm: approx. 35°C, humid: relative humidity approx. 95%), with a limit of quantification (LOQ) of 1.4 µg m^{-3} alpha-Cypermethrin in air.

Principle of the method

Air is sucked through XAD adsorption tubes at about 1.0 L min^{-1} for 6 hours (total air sampling volume ~0.36 m^3). Subsequently, the adsorption material is extracted with ethyl acetate, the internal standard lambda-cyhalothrin is added to the extract, and finally analyzed by gas chromatography with mass spectrometric detection in the negative chemical ionisation mode (GC/MS(NCI)), monitoring three fragment ions.

The limit of quantification is defined as the lowest fortification level used in the validation process corresponding to a concentration of 1.4 µg m^{-3} alpha-Cypermethrin in air.

Recovery findings

The analytical method was validated with warm, humid air (approx. 35°C, approx. 95% relative humidity) at fortification levels of 0.50 µg and 5.0 µg per adsorption tube, corresponding to about 1.4 µg m^{-3} (LOQ) and about 14 µg m^{-3} (10xLOQ) and the results showed that recoveries were between 70% and 110%. Extraction efficiency was demonstrated with average recoveries between 98 to 99%. Average recoveries from the frozen storage stability test were between 95 to 97%. The average recoveries for both fortification levels and three ions after sampling of warm, humid air ranged between 86% and 102%. For each fortification level the RSD values were <20%. The detailed results are given in Table 4.2-15.

Table 4.2-15: Results of method validation of alpha-Cypermethrin in air

Specimen Type	Fortified alpha-Cypermethrin [µg]	Average C_{Air} [µg m^{-3}]	m/z 207		m/z 209		m/z 171		n
			Average Recovery [%]	RSD [%]	Average Recovery [%]	RSD [%]	Average Recovery [%]	RSD [%]	
Extraction Efficiency	5.0	--	99	3	98	2	99	2	4
Storage Stability: 6 Days, Freezer Temperature (approx. -20°C)	5.0	--	95	--	95	--	97	--	2
Warm, Humid Air	0.5	1.39	102	6	102	6	102	7	5
	5.0	13.9	86	12	87	11	88	12	5
	Overall		94	12	95	11	95	12	10

Linearity

Good linearity ($r > 0.99$) was observed in the range of 10 ng mL^{-1} to 300 ng mL^{-1} for three mass transitions of alpha-Cypermethrin.

Specificity

Under the described conditions the method is specific for the determination of alpha-Cypermethrin in air. Significant interferences (> 30% of LOQ) were not observed at the retention time and mass transitions of alpha-Cypermethrin.

Due to the high selectivity and specificity of GC/MS(NCI) an additional confirmatory technique was not necessary. Three mass transitions of alpha-Cypermethrin were quantified.

Limit of Quantification

The method has a limit of quantification (LOQ) of 1.4 µg m^{-3} alpha-Cypermethrin in air.

Repeatability

The relative standard deviations (RSD, %) for all fortification levels were below 20%.

Reproducibility

Reproducibility of the method was not determined within this validation study.

Storage Stability:

The average recovery after storage at -20 °C for 6 days on the adsorber material was 95%, hence test tubes can be stored for this period of time after air sampling until analysis.

Conclusion

Based on the results obtained, an analytical method for the determination of alpha-Cypermethrin in air using highly selective GC/MS(NCI) determination (monitoring three fragment ions) was successfully validated with a limit of quantification of 1.4 µg m^{-3}. The method fulfils the requirements of SANCO/825/2000 rev. 8.1, 16/11/2010 and SANCO/3029/99 rev. 4, 11/07/2000.

Report:	CA 4.2/10
	Maas X., Bendig P., 2015
	Validation of Analytical Method L0265/02 for the Determination of alpha-Cypermethrin (BAS 310 I) in Air
	2015/1225669
Guidelines:	SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes
	(certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

The objective of this study was to validate an analytical method L0265/02 for the determination of alpha-Cypermethrin (BAS 310 I) in air using GC/MS, with a target limit of quantitation (LOQ) of 0.06 µg/m^3. The target LOQ is based on the new (reduced) $AOEL_{inhalative}$ of 0.0004 mg alpha-cypermethrin /kg body weight which is based on a value of 0.25 mg/kg and applying a safety factor of 300 and another factor of 2 resulting in an overall safety factor of 600.

Principle of the method

Air was sucked through XAD adsorption tubes at about 1.0 L/min for 6 hours (total air sampling volume of about 0.36 m^3). Subsequently, the adsorption material is extracted with ethyl acetate, the internal standard lambda-cyhalothrin is added to the extract, and finally analysed by gas chromatography with mass spectrometric detection in the negative chemical ionisation mode (GC/MS), monitoring three fragment ions.

The validation was performed at LOQ and at 10 times LOQ fortification levels, each with 5 replicates and 2 untreated control samples.

The matrix effects were tested for each fragment ion. No significant matrix effects (i.e. > 20% suppression or enhancement) on GC-MS response were observed. Thus, calibration solutions in solvent were used for evaluation of the results. The following negative fragment ions of alpha-Cypermethrin were used for the analysis by GC-MS on a capillary GC-column (Optima 5 HT, 30 m, 0.25 mm i.d. 0.25 µm film thickness):

-207 m/z for quantification

-209 m/z for confirmation

-171 m/z for confirmation

Recovery findings

The analytical method was validated with warm, humid air (approx. 35°C, ≥80% relative humidity) at fortification levels of 0.06 µg m^{-3} (LOQ) and about 0.6 µg m^{-3} (10xLOQ) and the results showed that recoveries were between 70% and 110%. Blank samples showed results <LoD and break-through samples were below 2% of the fortification level, hence absence of break-through can be postulated.

Extraction efficiency was demonstrated to range between 103 and 106%. Average recoveries from the frozen storage stability test were between 92 and 103%. The average recoveries for both fortification levels and three ions after sampling of warm, humid air ranged between 94% and 98%. For each fortification level the RSD values were <20%. The detailed results are given in Table 4.2-16.

Table 4.2-16: Results of method validation of alpha-Cypermethrin in air

Specimen Type	Average C_{Air} [µg/m^3]	Fortified alpha-Cypermethrin [µg]	m/z 207		m/z 209		m/z 171		n

Linearity

Good linearity ($r^2 > 0.99$) was observed in the range of 0.4 ng mL^{-1} to 50 ng mL^{-1} for three fragments of alpha-Cypermethrin. Matrix effects were assessed and found to be not significant for the XAD resign. Hence, calibration was accomplished in solvent without matrix load in pure ethylacetate containing the internal standard.

Specificity

Under the described conditions the method is specific for the determination of alpha-Cypermethrin in air. Significant interferences (> 30% of LOQ) were not observed at the retention time and mass transitions of alpha-Cypermethrin.

Due to the high selectivity and specificity of GC/MS(NCI) an additional confirmatory technique was not necessary. Three mass transitions of alpha-Cypermethrin were quantified.

Limit of Quantification	The limit of quantification (LOQ) of the analytical method is 0.06 µg/m^3. The limit of detection (LOD) of the method was defined as the lowest analyte concentration injected as a calibration solution, resulting in an LOD of 0.012 µg/m^3 (equal. 20 % of the LOQ).
Repeatability	The method L0265/02 is suitable for the determination of alpha-cypermethrin in air. The mean recovery values were between 70 % and 110 % of the nominal values. The relative standard deviations for all fortification levels were below 20%.
Reproducibility	Reproducibility of the method was not determined within this validation study.
Storage Stability:	The average recovery after storage at -20 °C for 11 days on the XAD adsorber material was 97%, hence test tubes can be stored for this period of time after air sampling until analysis. Extracts, as well as stock solutions in ethylacetat and calibration solutions have been confirmed to be stable over a time period of 14 days.
Conclusion:	**It could be demonstrated that method L0265/02 fulfils the requirements with regard to specificity, repeatability, limit of quantification and recoveries and is therefore applicable to correctly determine residues of alpha-cypermethrin in air with a limit of quantification of 0.6 µg/m^3 air. The method is considered fully validated according to SANCO/825/00 rev. 8.1.**

(d) Methods for the analysis in body fluids and tissues

Analytical methods for the determination of alpha-Cypermethrin residues in body fluids were evaluated in the context of the inclusion in Annex I of Directive 91/414/EEC. Methods evaluated previously are summarized in Table 4.2-17 for the reviewer´s convenience.

Table 4.2-17: Peer-reviewed methods for body fluids and tissues

Method No.	Matrix	Method principle	Target analytes	LOQ	year	DocID	EU reviewed
DFG S 19	Blood, urine (swine)	GC/ECD	Alpha-Cypermethrin	0.005 mg/l	2000	AL-245-008	yes

Report:	CA 4.2/11 Bendig P., 2014a Validation of BASF analytical method L0246/01: Method for the determination of individual or combined diastereomeric forms of BAS 311 I (Cis I, Cis II (alpha-Cypermethrin, BAS 310 I), Trans III and Trans IV) in body fluids 2014/1145911
Guidelines:	SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

Remark: The title has slightly changed compared to the one originally submitted in the application. The title as presented now in the dossier reflects the purpose of the study a more appropriate manner. A BASF-method number was also allocated to unequivocally identify the method. The originally assigned title was "Development and validation of an Analytical Method for the Determination of alpha-Cypermethrin, BAS 310 I in body fluids", however by the assigned DocID 2014/1145911 the study can be unequivocally identified.

Principle of the methods

Urine: Acetonitrile extraction of urine with consecutive dilution and LC-MS/MS determination (with positive ionisation: ESI) was used for quantitation and confirmation.

Blood plasma: A small scale DFG S19 extraction module E7 was used for extraction of the blood plasma. An aliquot of the extract was evaporated to dryness and then redissolved in acetonitrile/water (1/1, v/v + 0.1% formic acid) followed by LC-MS/MS determination (with positive ionisation: ESI) for quantitation and confirmation.

The limit of quantification (LOQ) of both methods is < 0.050 mg/L per analyte.

Recovery findings

The urine and blood plasma (5 replicates) were fortified at ≤ 0.050 mg/L per isomer (LOQ) with solutions containing all 4 Cypermethrin isomers. The fortification level of Cis II isomer (alpha-Cypermethrin) was 0.035 mg/L. The average recoveries for the two parent-daughter ion transitions monitored were within the acceptable range of 70 % to 110 %.

Matrix effects were not significant (i. e. < 20 %). Nevertheless, quantitative determination of final urine and blood plasma extracts was carried out by external standardization using matrix matched standard solutions.

Detailed results of recoveries for each mass transition and crop are given in Table 4.2-18. Effects of matrix on response are demonstrated in Table 4.2-19.

Table 4.2-18: BASF analytical method L0246/01, summary of validation results

	55	1.0	MMS	054	8.15E+04		5.27E+04		3.18E+04		1.99E+04	

Calibration used for quantitation: Calibration solutions in solvent ("S"). MMS: Matrix-matched standards.
*A positive value indicates enhancement, a negative value suppression.

Linearity	Good linearity (regression coefficients ≥ 0.999) was observed in the range of 0.20 ng/mL to 5.00 ng/mL or 10.00 ng/mL for Cis I and Trans III (Cis II and Trans IV in the given ratios).
Specificity	Quantification was performed by use of highly selective LC-MS/MS detection. Two selected ion mass transitions were evaluated in order to demonstrate that the method achieves a high level of selectivity. No significant interference above 30 % of LOQ was detected in any of the control specimen extracts, so that a high level of selectivity was demonstrated.
Limit of Quantification	The limit of quantification for both methods was ≤ 0.050 mg/L per analyte.
Repeatability	For each fortification level, for urine and blood plasma and for both MS/MS transitions monitored, the relative standard deviations (RSD) were always below 20%. The detailed values are shown in Table 4.2-18.
Reproducibility	Reproducibility of the method was not determined within this validation study.
Conclusion	**The LC-MS/MS based methods were successfully validated for the determination of all 4 Cypermethrin isomers in human urine and blood plasma with an LOQ of ≤ 0.050 mg/L and thus demonstrated to be applicable for enforcement and monitoring purposes.** **The method fulfills the registration requirements of SANCO/825/00 rev. 8.1 16/11/2010 and SANCO/3029/99 rev.4 11/07/2000.**

Report:	CA 4.2/12 Richter S., 2015 BAS 310 I (alpha-Cypermethrin): Bridging Extractability of BAS 310 I (alpha Cypermethrin) from Barley Grain, Olive Fruit and Orange Whole Fruit using Acetonitrile/Water (3 Methods, incl. QuEChERS) or Methanol/Water/HCl (BASF Method 567/1) as Extraction Solvents DocID 2014/1162676
Guidelines:	SANCO/825/00 rev. 8.1 (16 November 2010), SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

Remark:
The presented OECD-summary of the study is based on under GLP audited data. However, as the report was not finalized at time of submission of the electronic version of the dossier, a copy of the original, signed final report of the study will be submitted upon availability, which is estimated to be early February.

Principle of the methods

The objective of this study is to bridge alpha-Cypermethrin's extractability when extracted with various solvent mixtures from acidic, dry, and oily crops.

QuEChERS based residue method for all 3 crop types (BASF-method No. L0245/01)
The QuEChERS method as validated in a previous study (BASF DocID 2013/1361966) was used for all crops, all untreated samples (single extraction) and all treated samples analysed in duplicate. Sample aliquots are extracted with a mixture of water and acetonitrile for subsequent LC/MS/MS analysis.

Residue method 567/1 for all 3 crop types (BASF DocIDs 2007/1010254 and 2005/500006)
Sample aliquots are extracted with a mixture of water and methanol (acidified with HCl) for subsequent LC-MS/MS analysis.

Residue method 567/0 for olive fruit (BASF DocIDs 2005/5000063 and 2005/500006)
Sample aliquots are extracted with acetonitrile and cleaned-up with n-hexane liquid-liquid partition for subsequent LC-MS/MS analysis.

Extraction for olive and orange as used in metabolism study AL-640-001

10 g of crop material are extracted twice, each time with 30 mL of acetonitrile/water (70/30 v/v), followed by centrifugation and LC-MS/MS analysis.

Extraction for barley grain as used in metabolism study AL-640-004

10 g of grain material are soaked with 5 mL of water, followed by 2-times extraction with each 40 mL of acetonitrile (0.1% formic acid), centrifugation and LC-MS/MS analysis.

The LC-MS/MS method allows to quantify and to confirm alpha-Cypermethrin, using two MRM transitions based on the formation of ammonium adducts (433 m/z -> 191 m/z and 435 m/z -> 193 m/z).

The limit of quantification (LOQ) of all methods is 0.01 mg/kg, the limit of detection was 0.002 mg/kg.

Residue results

Unlabeled samples from field trials were analysed using the various solvent mixtures.

For whole orange, the 3 extraction methods QuEChERS (BASF method No. L0245/01), BASF method 567/1 and the extraction method from the metabolism study AL-640-001 resulted in almost similar residue results for alpha-Cypermethrin.

Residue results of alpha-Cypermethrin in olive fruit are comparable for the extraction methods QuEChERS (BASF method No. L0245/01), BASF method 567/0 and the extraction method from the metabolism study AL-640-001. Results obtained with BASF method 567/1 were corrected for the low recovery results obtained from the concurrent fortified samples and are similar to those residue results found with the other extraction methods.

Residue results for barley grain obtained with the QuEChERS method (BASF method No. L0245/01) and the extraction method from the metabolism study AL-640-004 are comparable. The extraction method 567/1 resulted in lower residues (in the same order of magnitude).

A summary of residue results of treated samples is given in Table 4.2-20.

Table 4.2-20: Extraction methods in plant materials; summary of residues results

Methods		QuEChERS (L0245/01)	567/0	567/1		AL-640-004	AL-640-001
Sample Type	Sample No.	Alpha-Cypermethrin residues (mg/kg)

na: not applicable

* Residue results are corrected for low recoveries of concurrent fortified samples.

Recovery findings

For concurrent method validation, plant materials were fortified (3 replicates per level and crop type) with solutions containing alpha-Cypermethrin to obtain fortifications levels at LOQ and at a higher level (100xLOQ).

Average recoveries for all three crop materials were within the acceptable range of 70 % to 110 % with relative standard deviations (RSD) of ≤ 20 % except for olive extracted with extraction method 567/1 with an average recovery of about 40 %. This low recovery was to be expected as the extraction method was not designed for alpha-Cypermethrin in oily matrices.

Detailed results of recoveries are given in Table 4.2-21.

Table 4.2-21: Extraction methods in plant materials; summary of validation results

Matrix	Fortification Level (mg/kg)	Alpha-Cypermethrin (433 m/z -> 191 m/z)			
		Average (%)	SD (%)	RSD (%)	n

SD=Standard Deviation, RSD=Relative Standard Deviation, n=Number of results included in calculation

* Low recovery as expected since the extraction method was not designed for alpha-Cypermethrin in oily matrices.

** Olive recoveries excluded.

Linearity Good linearity (correlation coefficients ≥ 0.999) was observed in the range of 0.01 ng/mL to 25 ng/mL.

Specificity Quantification was performed by use of highly selective LC-MS/MS detection. Two selected ion mass transitions were evaluated in order to demonstrate that the method achieves a high level of selectivity. No significant interference above 20% of LOQ was detected in any of the control specimens.

Limit of Quantification The limit of quantification (LOQ) of the methods is 0.01 mg/kg.

Repeatability The relative standard deviations (RSD) were always below 20%. The detailed values are shown in Table 4.2-21.

Stability in Solutions and Extracts

Standard solutions and final extracts were stored refrigerated in the dark when not in use. Solutions with the analyte were used throughout the study and gave consistent results and recoveries. Acceptable recoveries for alpha-Cypermethrin in crop sample extracts stored refrigerated for several days demonstrate the stability of the analyte during refrigerated storage.

Conclusion

For alpha-Cypermethrin, the methods showed good results with regard to the parameters studied. No significant differences among the validated residue methods for the extraction of alpha-Cypermethrin were found. Solely in the case of method 567/1 lower recoveries for oily matrices were found compared to the extraction scheme of the metabolism studies. However, method 567/1 was not specifically developed for matrices of high oil content, whereas method 567/0 which shows satisfactory high extraction efficiency of > 70%.

CA 5 TOXICOLOGICAL AND METABOLISM STUDIES ON THE ACTIVE SUBSTANCE

Introduction

This chapter is preceded with a

- **Bridging situation** for alpha-cypermethrin
- **Bridging rational** to compare alpha-cypermethrin with cypermethrin, zeta-cypermethrin and beta-cypermethrin and to conclude on the consequences of bridging between the data.

The data are presented as follows:

- **Studies already evaluated in the draft monograph of alpha-cypermethrin combined with data from other DARs belonging to the group of cypermethrins:** for completeness short summaries of key investigations from the divers DARs are presented in case where the data are no longer data protected (with headers presented in the original monograph). These studies are highlighted in grey. In case of data protection we kindly refer to the original DAR and give only summary tables.
- **Submission of not yet peer-reviewed studies in this AIRIII-Dossier:** new data are presented and discussed in detail.

Bridging situation for alpha-cypermethrin:

Alpha-cypermethrin has been investigated in a huge package of regulatory studies and data from other cypermethrins were already used in the first Annex I registration to supplement the regulatory datapackage and were regarded as acceptable for the Renewal process:

- the rat carcinogenicity study has been addressed with data generated for cypermethrin and
- the multi-generation data with alpha-cypermethrin were supplemented with cypermethrin data

New data to account for the potential developmental neurotoxicity as requested for pyrethroids in general in the Review report of alpha-cypermethrin (SANCO/4335/2000 final) are now addressed via data from zeta-cypermethrin that are no longer data protected.

- a developmental neurotoxicity study with zeta-cypermethrin (CA 5.7)

Lactational and placental transfer as well as milk concentration is addressed with the following studies:

- Dietary placental transfer and lactation transfer of zeta-cypermethrin at 50, 125, 300 ppm in rats from GD 6-20, or GD6-LD21 (see CA 5.8.2)
- Measurement of zeta-cypermethrin in milk following dietary administration at 125 and 375 ppm from GD 6 to LD 17 (see CA 5.8.2)

A new DNT study with direct pup dosing as requested by the rapporteur is presented:

- Targeted developmental neurotoxicity study with direct pup dosing addressing the most sensitive endpoints found in the study described in the DAR of beta-cypermethrin (see CA 5.7)

Important to mention: Based on the proven lactational transfer of cypermethrins on the one side, and the artificial exposure type of direct pup dosing on the other side, the findings of this study are considered not appropriate and not relevant to be used in a human risk assessment for infants which are mainly exposed via breast or bottle fed.

The exposure via rat breast milk is exceeding the human exposure by several orders of magnitude (see CA 5.8.2) and therefore the dietary DNT study with zeta-cypermethrin is considered as the relevant study to derive an endpoint for human risk assessment.

The generation of a dietary developmental neurotoxicity study with alpha-cypermethrin itself is considered not necessary based on the huge database available for pyrethroids and the principal similarity of toxicity as outlined in the following bridging rationale.

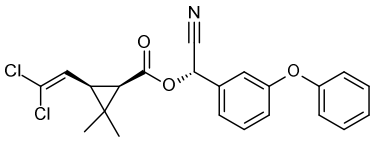
Further information from other international authorities:
The US EPA evaluated the existing database for Pyrethroids in the Memorandum “Pyrethroids: Evaluation of Data from Developmental Neurotoxicity Studies and consideration of Comparative Sensitivity” [see KCA 5/6 2010/1232203], including zeta-cypermethrin and three other Typ II Pyrethroids. It was concluded that guideline DNT studies with dietary administration are not appropriate to provide new information which is relevant for risk assessment.

Also on European level within the Biocides Technical Meetings (TM III 09, TM I 10, TM II 2010) the relevance of DNT studies with pyrethroids were discussed. The following conclusion was drawn: *”As neurotoxic effects are critical effects after acute or medium-term exposure and the available data indicate that DNT effects are induced at higher LOAELs, it is unlikely that, in the absence of DNT studies, the potential DNT effects are not covered by AELs set on neurotoxic effects observed in acute and mediumterm studies. The data also indicate that an additional assessment factor for species sensitivity is not required. It was concluded that additional DNT studies according to OECD TG 426, if such a study is not present, is not necessary.” (TM II 2010, page 4-5)*

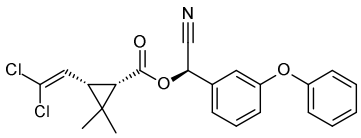
Bridging rationale

Alpha-cypermethrin is an insecticide that belongs to the class of Typ II pyrethroids, which contain the □-cyano-3-phenoxybenzyl moiety whereas Type I compounds are lacking the □-cyano-3-phenoxybenzyl group. Alpha-cypermethrin consists of 2 of the 8 stereo isomers that comprise cypermethrin, the Cis2 Isomers. For clarity, the two stereo isomers of alpha-cypermethrin (1R cis □S and 1S cis □R) are shown in Figure 5-1.

Figure 5-1: Stereoisomers of alpha-cypermethrin



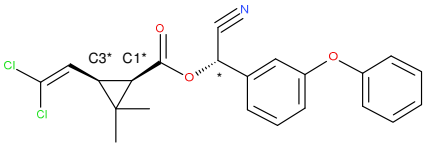
1R cis αS



1S cis αR

Cypermethrin in comparison is a racemic mixture of 8 isomers (with 3 chiral centres as shown in Figure 5-2) and contains around 22% of alpha-cypermethrin. In Table 5-1 all cypermethrins are listed with regard to their isomer composition and biological activity.

Figure 5-2: Structure of cypermethrin and location of its chiral centres



*: denotes the positions of chiral carbon centres

Table 5-1: Composition of the different cypermethrins

Isomers of Cypermethrin C1 α-carbon		Receptor Inhibition[a]	Mouse toxicity[b]	Cyper-methrin [%]	Alpha-cypermethrin [%]	Beta-cypermethrin [%]	Theta-cypermethrin [%]	Zeta-cypermethrin [%]

[a] Lawrence and Casida (1983), DocID 1983/1002378, inhibition of [35S]t-butylbicyclophosphorothionate binding to rat brain synaptic membranes relative to the potency of 1R cis αS isomer at 5µM set to 100%

[b] Lawrence and Casida (1983), DocID 1983/1002378, Toxicity is relative to 1R cis αS isomer with a mouse intracerebral LD_{50} of 1.4 nmole per gram of brain tissue determined by injection in 3 µl of methoxytriglycol into the third ventricle.

The bridging concept of cypermethrins is based on the shared toxicity profile relevant for Reference value setting, which is acute neurotoxicity. Even though there have been a lot of investigations within the last decades about possible targets of mammalian intoxication as summarized in the reviews of Soderlund et al., 2002 [see KCA 5/1 2002/1027257] and Soderlund, 2012 [see KCA 5/2 2012/1367222], there is still a broad agreement that **voltage-gated sodium channels are the primary target sites for the neurotoxic action of pyrethroids.** The stereospecific interaction of different isomers of pyrethroids with voltage-gated sodium channel was extensively investigated in vitro (Narahashi, 1986, KCA 5/3 1986/1002771) and also in vivo (Lawrence and Casida, 1983 and 1985, [see KCA 5/4 1983/1002378 and KCA 5/5 1985/1002192]).

Other stereospecific mode of actions like blockage of voltage-sensitive calcium and chloride channels, associated with the production of salivation (Soderlund, 2012, [see KCA 5/2 2012/1367222]; Meijer et al., 2014, [see KCA 5/7 2014/1242699]), have been implicated as alternative or secondary sites of action but, like other potential neuroactive targets (voltage-sensitive potassium-channels, ligand-gated ion channels (i.e. GABA- and Nicotine acetylcholine-receptors as well as excitatory glutamate receptors), peripheral-type benzodiazepine receptors, ion channel and receptor regulation as well as mitochondrial electron transport) failed to demonstrate relevance to pyrethroid intoxication and are therefore not considered in the literature search of alpha-cypermethrin as relevant.

Based on the most relevant mode of action, the lesions exerted by cypermethrins are primarily manifested as acute and reversible pharmacological actions resulting from nerve excitability (Ray & Frey, 2006, [see KCA 5/8 2006/1051137]; Ray, 2001, [see KCA 5/9 2001/1032003]), and although the different cypermethrins are separate active ingredients, they are considered as similar in their primary toxicity profile of neurotoxicity based on the following considerations:

1. The neurotoxicity of pyrethroids to mammals depends on structural characteristics:

   - The stereochemical configuration at cyclopropane C-1:

     only esters of 1R cyclopropanecarboxylates are neurotoxic in mammals, whereas the corresponding 1S is without measurable toxicity even when administered at high doses directly to the CNS (Soderlund et al, 2002, [see KCA 5/1 2002/1027257]).
     The 1R to 1S ratio is similar for all cypermethrins, indicating that no relevant difference concerning neurotoxicity is expected by this property only.

   - the presence of an□□-cyano substituent in S configuration in the 3-phenoxybenzyl alcohol moiety:

     A pyrethroid with an □-cyano substituent in S configuration also greatly enhanced acute neurotoxicity while the R epimer was not toxic (Soderlund et al, 2002, [see KCA 5/1 2002/1027257]). In a paper published by Casida and Lawrence (1985, [see KCA 5/5 1985/1002192]) the inhibitory potency of α-cyano 3-phenoxybenzyl pyrethroids at the butylcyclophosphorothionate (TBPS) receptor on fresh rat brain membranes was studied. In parallel, toxicity was evaluated on intracerebrally treated mice and the potency of the different isomers was compared to that of Cis R α-S cypermethrin which is normalized to 100. This study demonstrated the potency of the Cis R α-S isomer of cypermethrin.
     The S/R ratio at □-carbon is 50/50 for all cypermethrins except for the isomeric improved zeta-cypermethrin, which is 89/11.

   - The cis/trans ratio at the cyclopropyl ring:

     In mammals, the absolute configuration at cyclopropane C-3 of cyclopropane carboxylate esters of primary alcohols also strongly influences toxicity. Pyrethroids having the 1R, cis configuration are both insecticidal and toxic to mammals, whereas the corresponding pyrethroids having the 1R, trans-configuration, though similar in insecticidal potency, lack measurable acute toxicity to mammals. The low toxicity of these 1R, trans-pyrethroids was once ascribed solely to their rapid hydrolytic detoxication by liver esterases. However, intra-cerebral dosing experiments have demonstrated that these compounds had low intrinsic toxicities even when the impact of biotransformation was removed (Soderlund et al, 2002, [see KCA 5/1 2002/1027257]). For the cypermethrin isomers 1R cis □S and 1R trans □S a factor of 2 to 3 difference between the cis and trans isomer was shown for the LD50 values after intracerebral injection in mice.

     The cis/trans ratio of cypermethrin and zeta-cypermethrin is 50/50 whereas that of alpha-cypermethrin is 100/0 and beta-cypermethrin is 40/60. Thereby alpha-cypermethrin can be considered as slightly more toxic than cypermethrin, beta- or zeta-cypermethrin.

Conclusion: Differences in neurotoxic potential at comparable plasma peak levels might occur to some extent based on the different active isomers.

2. The neurotoxicity of cypermethrins depends on the substance concentration at the voltage-gated sodium channels as primary target sites for the neurotoxic action of pyrethroids

   Bioavailability is determined by identical physico-chemical properties (low solubility in water and high solubility in fat, pH-dependent hydrolytic stability and molecular weight) and similar toxicokinetic properties. This is substantiated by data generated with cypermethrin, alpha-cypermethrin and zeta-cypermethrin:

   - Absorption and excretion is rapid and comparable. The neurotoxic symptoms are correlated with the plasma concentration, which increase and decrease rapidly showing a short peak plasma effect at Tmax within 3-9 hours

   - Distribution of cypermethrins takes place in well perfused (liver, lung, kidney and heart) or lipophilic organs (fat). Storage within the lipophilic cell membrane apart from voltage-gated sodium channels will not contribute to neurotoxic symptoms but might induce other non-specific effects like for example oxidative stress. The terminal half-life for elimination of alpha-cypermethrin from the fat of rats is 17-26 days, compared to 18.9 days for cis-cypermethrin (WHO, 1992, [see KCA 5/10 1992/1005337]).

   Conclusion: Absorption and excretion are comparable, accumulation in fat is not considered to crucially contribute to neurotoxic symptoms.

3. Neurotoxicity is terminated via metabolic degradation.

   All Cypermethrins are primarily metabolized by cleavage of the ester bond releasing two common metabolites:
   - 3-phenoxybenzoic acid (PBA) and
   - 3-(2,2-dichlorovinyl)2,2-dimethylcyclopropanecaroxylic acid (DCVA).
   - common metabolites are furthermore conjugated and hydroxylated.

   Conclusion: Neurotoxic effects will occur mainly after bolus administration where plasma peak levels are reached by exceedance of the metabolic capacity. At human relevant doses reflected by the experimental dietary administration studies systemic toxicity is mainly characterized by the toxicity of the common metabolites.

In addition, it has been shown that the magnitude of the induced toxicity in bolus studies can vary by several orders, and is modulated by factors like: species and strain, vehicle, age of animals, intrinsic binding, fasted or unfasted animals. This is comprehensively described in the open literature for pyrethroids, see Crofton et al. (1995, [see KCA 5/11 1995/1008154]) and Wolansky et al. (2007, [see KCA 5/12 2007/1070388]). Therefore the variability within the test system dominates the variability of substance specific toxicity.

Therefore, although there might be differences in structure activity factors (R/S ratio at C1, cis/trans ratio) that influence mammalian (neuro-) toxicity of the Typ II-pyrethroids cypermethrin, alpha-, beta-and zeta-cypermethrin, overall no relevant differences in mammalian toxicity is expected in correlation to biological variability between the different cypermethrins when focusing on risk related studies and not on hazard related acute lethal toxicity studies. This is confirmed by a number of studies performed with different cypermethrins and presented within the following tables for acute neurotoxicity and repeated dose studies.

The following Table 5-2 and Table 5-3 demonstrate that differences in acute neurotoxicity study results are rather due to biological variability than due to a different toxicological profile of the cypermethrins:

Table 5-2: Acute neurotoxicity studies

Compound studied	Strain*	Age of animals	Dose [mg/kg bw] vehicle	Neuro NOAEL [mg/kg/d]	Neuro LOAEL [mg/kg/d]	Reference
Alpha-cypermethrin[1]	SD (Crl:CD:BR)	6-7 weeks	0-4-20-40 in 10 ml/kg corn oil	4	20	[redacted] 1993b [see KCA 5/13 AL-451-004]
Zeta-cypermethrin[4]	LE	Not given	0-10-50-250 mg/kg bw undiluted	10	50	[redacted] 1998

2 Study reported in the DAR beta-cypermethrin (2013)
3 Study reported in the DAR cypermethrin (1999)
4 Study reported in the DAR zeta-cypermethrin and Final Addendum (2008)

These data are supplemented by acute oral toxicity studies published by Wolansky et al. (2006, [see KCA 5/14 2006/1051134]) and Weiner et al. (2009, Doc ID [see KCA 5/15 2009/1131083]) using several doses and a relatively high number of animals per dose group.

Table 5-3: Acute neurotoxicity studies from peer-reviewed literature

Compound studied	Strain* Number/group Age of animals	Study Type	Doses [mg/kg bw] vehicle	NOAEL [mg/kg bw]	LOAEL [mg/kg/d]	Reference
Cypermethrin	LE 8-18/dose 9 weeks	Acute Oral Toxicity – Motor Activity	0.1-0.4-1-10-40 120 1 ml/kg corn oil	1	10	Wolansky et al., 2006, [see KCA 5/14 2006/1051134]
Cypermethrin	SD (Crl:CD:BR) 10/dose 6 weeks	Acute Oral Toxicity – FOB	65-100-150 5 ml/kg corn oil	<65	65	Weiner et al., 2009, [see KCA 5/15 2009/1131083]

*Threshold dose: estimate of the highest no-effect dose level at which treated rats would not display any decrease in motor activity.

Overall, the acute neurotoxicity studies on cypermethrin reflect the huge variability of NOAELs (1-30 mg/kg bw/day) and LOAELs (10-100 mg/kg bw/day). It has to be noted that the variability of effect and no effect levels for cypermethrin alone is higher than the differences observed for the whole group of cypermethrins.

The same is true also for repeated dose toxicity studies performed with the different cypermethrins. In these studies neurotoxic symptoms are no longer critical for NOAEL setting but appear together with further symptoms of toxicity or even at higher doses.

1 Study reported in the DAR alpha-cypermethrin (1999); 2 Study reported in the DAR beta-cypermethrin (2013); 3 Study newly submitted within this Annex III dossier
4 Study reported in the DAR zeta-cypermethrin Final Addendum (2008); 5 Study reported in the Alpha-Cypermethrin Human Health Risk Assessment report, EPA; DP No D37609, 2012

Comparing the NOAELs and LOAELs from the repeated dose studies, neurotoxicity does not seem to progress with prolonged exposure, which is consistent with the kinetic profile for pyrethroids. Differences in toxicity are less than one order of magnitude and follow no substance-specific ranking but are mainly explainable via substance unrelated parameters as dietary vs. capsule feeding vs. gavage in different vehicles, different strains and age of animals.

Similar toxicity is also seen when comparing other endpoints: All cypermethrins are of no acute toxicity via the dermal route, are harmful via inhalation, were evaluated as being non-irritants to skin and eye (persistent discolouration led to classification of beta-cypermethrin), induce no skin sensitization except for zeta-cypermethrin. Furthermore alpha-, beta-, zeta-cypermethrin and cypermethrin itself show no genotoxicity or carcinogenicity. Reproductive and developmental effects were restricted to reduced litter size and reduced pup body weight at maternally toxic doses.

Concerning this general similarity, no difference is expected between alpha-cypermethrin and any other cypermethrin with regard to the developmental neurotoxicity study and the lactational and/or placental transfer. The same applies for ADME data, where studies were taken from cypermethrin and alpha-cypermethrin already for the first Annex I inclusion. The same is true for the multi-generation study which was submitted by Gharda with alpha-cypermethrin as test substance, and supported by cypermethrin data.

A more in depth discussion of the toxicological similarity of cypermethrin, zeta-cypermethrin and alpha-cypermethrin was submitted to the US EPA in 2009 [see KCA 5/21 2009/7003352] to waive the need of a dietary DNT study with alpha-cypermethrin. US EPA accepted the waiver and evaluated the hazard of alpha-cypermethrin in combination with cypermethrin and zeta-cypermethrin due to structural and toxicological similarities and comparable toxicity profiles (US EPA, 2012; [see KCA 5/22 2012/1367302]).

Conclusion with regard to bridging consequences:

Based on the substantial similarity of alpha-, zeta- , beta-, and cypermethrin as discussed based on comparable data (see
Table 5-4: Comparison of repeated-dose toxicity studies performed with Cypermethrin, Zeta-cypermethrin, Alpha-cypermethrin and Beta-cypermethrinTable 5-2 -
Table 5-4), no additional assessment factor is considered necessary when bridging study results within the group of cypermethrins. Furthermore all relevant studies for endpoint derivation were performed with alpha-cypermethrin itself.

CA 5.1 Studies on Absorption, Distribution, Metabolism and Excretion in Mammals

CA 5.1.1 Absorption, distribution, metabolism and excretion by oral exposure

Studies evaluated in the draft monograph of alpha-cypermethrin (1999): Alpha-cypermethrin is a component of cypermethrin, and there is no indication that it would have different toxicological effects. Therefore, ADME studies of alpha-cypermethrin have been evaluated together with data from cypermethrin studies and metabolic pathways were elucidated in rats following oral administration (List of studies is presented under CA 5.1.1). The Annex I endpoints were fixed in the Review report of alpha-cypermethrin (SANCO/4335/2000 final from 13 February 2004) as follows:

Absorption, distribution, excretion and metabolism in mammals

Rate and extent of absorption:	46% within 24 h
Distribution:	Widely distributed, highest residue in fat and skin
Potential for accumulation:	High accumulation in fat
Rate and extent of excretion:	76-78% within 24 h (43-46% in urine; 30-35% in faeces)
Toxicologically significant compounds:	Parent compound
Metabolism in animals:	± 50 % metabolised via hydrolytic cleavage of ester bound

The different formulations used for absorption, distribution, metabolism and excretion studies are summarized in table below:

Table 5.1.1-1: Characteristics of the formulations of alpha-cypermethrin and cypermethrin used in the metabolism studies

Submission of not yet peer-reviewed studies in this AIRIII-Dossier: A study on oral adsorption kinetics, distribution and excretion of **alpha-cypermethrin** is supplementing the already available data and is discussed in this chapter under point KCA 5.1.1/1 AL-440-017. A verification of the **metabolite identification** in rats is discussed under KCA 5.1.1/2 2013/1086630. Additionally, the dermal absorption of alpha-cypermethrin has been investigated in the representative formulation in vitro in human skin and revealed a maximum absorption of 3% for the concentrate (see KCP 7.3).

According to the new data requirements for active ingredients of plant protection products as set out in Commission Regulation (EU) No. 283/2013 (1 March 2013, OJ L93, 1ff, 3.4.2013), "comparative *in vitro* metabolism studies shall be performed on animal species ... and on human material ...in order to determine the relevance of the toxicological animal data and to guide in the interpretation of findings and in further definition of the testing strategy..." (Section 5, Toxicological and metabolism studies, point 5.1.1., page 22). In the absence of validated test method or guidance documents, this data requirement is waive in accordance to SANCO Guidance Document SANCO/10181/2013-rev 2.1 (13 May 2013).

Table 5.1.1-2: Characteristics of the formulations of alpha-cypermethrin used in the ADME studies newly submitted

Substance	Position of label, Batch No.	Vehicle	Radiochemical purity (%)	Reference

A new rat study on absorption, distribution and excretion of alpha-cypermethrin as well as a detailed metabolism is available which extends and augments the previous studies (List of studies is presented under CA 5.1.1). Additionally, the dermal absorption of alpha-cypermethrin has been investigated in the representative formulation in vitro in human skin and revealed a maximum absorption of 3% for the concentrate (see KCP 7.3).

When information from the older and new studies is reviewed in total, the following endpoints are proposed as an update without changing the relevant endpoints.

Proposed endpoints for Absorption, distribution, excretion and metabolism in mammals

Rate and extent of absorption:	Relatively rapid; Tmax 6-9 hours; Oral absorption : 46 %, considering urinary and biliary excretion (within 48 h), and carcass residuals.
Distribution:	Widely distributed, mainly in well perfused organs (mesenteric lymphnode, liver, kidney) and lipophilic organs (fat, brown fat).
Potential for accumulation:	Accumulation in fat (T½ (fat) > 24h),
Rate and extent of excretion:	24 h: 79-87% (urine: 31-39%; faeces: 39-55%) 48 h: 92-94% (urine: 34-46%; faeces: 46-60%)
Toxicologically significant compounds:	Parent compound
Metabolism in animals:	± 50 % metabolised via hydrolytic cleavage of ester bound

The summary of these ADME studies is as follows:

Absorption: Oral absorption of alpha-cypermethrin is relatively rapid with Tmax reached within 6-9 hours. After single oral application approximately 46 % of the dose is absorbed within 48 hours [redacted] 1982 and confirmed in KCA 5.1.1/1 AL-440-017). After 168 hours up to 50 % is considered bioavailable based on urinary excretion, bile excretion and residual carcass radioactivity [see KCA 5.1.1/1 AL-440-017]. The presence of large unchanged portions of the dose in faeces may be interpreted as a sign of limited absorption in the gastro-intestinal (GI) tract and may be considered as potentially non-absorbed [redacted] 1978; [redacted] 1980).

Distribution: Alphacypermethrin is widely distributed, mainly in well perfused organs (mesenteric lymphnode, liver, kidney) and lipophilic organs (fat, brown fat). Distribution and elimination from tissues is rapid, for example the half-life in plasma is biphasic with 4 and 6-8 hours for low and high dose (rapid initial depletion) and around 24 h in a slower second phase (AL-440-017), half-life in liver and kidney is ca. 2 days ([redacted] 1983). The depletion of alpha-cypermethrin from adipose tissue is biphasic with half-lives of ca. 2 days (rapid initial depletion) and 17-26 days (slower second phase), compared to a second phase of 18.9 days for cis-cypermethrin (WHO, 1992, [see KCA 5/10 1992/1005337]).

Metabolism: Alphacypermethrin, like Cypermethrin, is extensively metabolised by ester cleavage [redacted] 1982) and subsequent elimination of the cyclopropanecarboxylic acid moiety largely as its glucuronic acid conjugate [redacted] 1977). The 3-phenoxybenzoic acid portion of the compound undergoes hydroxylation and sulphate conjugation (major route) prior to excretion [redacted] 1982). The major metabolite determined in urine was 3-(4- hydroxyphenoxy) benzoic acid-O-sulphate conjugate (34–40 % of the dose). In faeces, mainly the unchanged parent compound was found (20 % of administered dose).
The present Annex I renewal dossier provides new metabolism studies using alpha-cypermethrin in goat, hen, fish and rat. The new studies mainly confirm the findings and degradation reactions known so far and complement additional details due to more sensitive technology.
The proposed metabolic pathway of Alphacypermethrin in rats is presented in Figure **5.1.1-1**.

Excretion: More than 92% of the radioactivity is excreted within 48 hours of administration, equally partitioned amongst feces and urine in females (both 46%) and slightly less in urine in males (34.2% via urine and 60% via feces). Excretion via bile is considered to be limited to around 3% in the first 24 hours. No radioactivity was excreted in the expired air.

General aspects: Apparent sex differences in the pattern of excretion and identified metabolites were not observed.

Human volunteer study: A human volunteer study was conducted in 1984 to determine oral absorption, and to develop a human biomonitoring procedure based on urinary metabolite analysis. There was no evidence of any accumulation after repeated oral administration of Alphacypermethrin to human volunteers. On average, 49 % of the dose was excreted as ciscyclopropane carboxylic acid, which is also a major metabolite in rats (van Sittert, 1984).

In the following already peer reviewed data taken from the different DARs as indicated are summarized and new data are attached at the end.

Absorption (taken from DAR alpha-cypermethrin, 1999, except where mentioned otherwise)

Oral absorption:

No animal studies measuring oral absorption kinetics of **alpha-cypermethrin** are available. On the basis of distribution, metabolism and excretion, it seems that after low or high dose of alpha-cypermethrin ±45% of the dose was excreted in urine; faecal excretion representing ±33% for the same period. Just over 20% of the compound is not absorbed and is eliminated unchanged in the feces.

As far as **cypermethrin** is concerned, the absorption process itself proceeds quite rapidly. The maximal concentration of radioactivity in the blood after oral administration of a low dose, reaches a maximum within 3-4 h and this for both sexes and for both labeling positions. Increasing the dose by a factor of 100 was followed by a 10-30 times increase in blood concentrations suggesting a saturable mechanism ([redacted] 1980).

After a low dose ±50% of cypermethrin administered was excreted in urine within a 24 h period (32-62% in urine, 16-35% in feces) ([redacted] 1977). Over a 3-7 day period 26-60% of radioactivity is eliminated in urine ([redacted] 1980).
Absorption of cypermethrin is incomplete representing ±50% of a low dose within the first 24 h after oral administration.

Human dermal absorption:

After a four hour dermal application of a formulation containing cypermethrin (49.6 mg) on the underside of the forearm, the formulation was removed and contained 33.4 mg cypermethrin; the dermal retained dose was therefore, 14.2 mg (±28%) by substraction. The cypermethrin metabolite dichlorocyclopropanecarboxylic acid (DCVA), and its free and conjugated forms, was not detected, i.e. <0.3 mg, in urine samples up to 96 h after dermal application.
Little is known about the fate of the remainder of the dose, which may have diffused into and be stored in a nurnber of skin layers and as such be, in part, available for further removal using the washing procedure (Coveney and Eadsforth, 1982).

Human data from the open literature:

Oral absorption:

Cypermethrin (cis/trans ratio = 1:1; 98.9-99.4% purity) was administered orally to 6 male volunteers as a single oral dose of 3.3 mg. Urine samples were collected for up to 5 days. Twice as much trans DCVA was excreted in urine compared to cis DCVA. From the urinary metabolite ratios found, it is apparent from DCVA/(3PBA+4HO-3PBA) ratio that more of the DCVA part of the molecule was accounted for compared to phenoxybenzyl moiety, indicating a greater proportion of the phenoxybenzyl moiety is converted to other metabolites. Peak excretion rates of metabolites occurred between 8 and 24 h after dosing. Based on metabolites measurements, the amount of absorbed dose was estimated between 27 and 57% (mean 36%) of the administered dose.

Dermal absorption:

Cypermethrin (cis/trans ratio = 1:1; 98.9-99.4% purity) was administered dermally to 6 volunteers at a dose range of 31 mg/800 cm^2 as a soya oil-based formulation. A substantial proportion of the dose (mean 41%) was recovered in the mild detergent wash after 8 h. The amounts of cyclopropane acid metabolites are 4 times lower than the amounts derived from the phenoxybenzyl moiety. This indicates that the cyclopropane acid part of the molecule may either not be effectively absorbed, or more probably is converted to other metabolites which are not measured using the assay procedure. The estimate of absorption of cypermethrin, based on cyclopropane acids is of 0.3% and 1.2% for phenoxybenzoic acid metabolites. 24% was recovered from a T-shirt worn overnight. Peak urinary excretion rates of metabolites occurred between 12 and 16 h after dermal dosing. A recovery of 66.55% can be calculated.
These results demonstrate two important differences in the excretion of urinary metabolites when cypermethrin is dosed orally and dermally. First the trans/cis DCVA ratio differs (oral 2:1; dermal 1:1.2) and secondly the ratio of total DCVA/phenoxybenzoic acid metabolites differs (oral 1:0.8; dermal 1:4). For the purpose of biological monitoring total DCVA could substantially underestimate absorption when dermal is the main route and the amount of total phenoxybenzoic acid metabolites will best reflect absorption of cypermethrin by all routes (Woollen et al., 1992).

Distribution (taken from DAR alpha-cypermethrin, 1999, except where mentioned otherwise)

Single dose studies

Maximal tissue concentration is reached 24 h after oral administration of a low or high dose of **alpha-cypermethrin**. At that time, appreciable quantities of test material were present in fat. For each of the fatty tissues there appears to be an initial rapid depletion of residues, with a half-life of about 2 days, followed by a second slower phase. $T_{1/2}$ blood was calculated as 6.4 h for a high dose and 8 h for a low dose ([redacted] unknown date).
Four days after single oral dose of **alpha-cypermethrin**, radioactivity detected in tissues did not exceed 0.01% of the administered dose. Some tissues retained higher amounts, liver (0.1%), skin (0.25%), carcass (0.9%) and intestines (0.3%). The highest concentration was found in adipose tissue (0.42%) ([redacted] 1982a).

Fourteen days after exposure to **alpha-cypermethrin** the concentration of radioactivity was at the detection limit in the majority of tissues except in fat, where an appreciable amount of radioactivity was still present [redacted] unknown date).

Some analysis of the peri-renal and parovarian fat was carried out in an attempt to identify the nature of the residue. It was found that more than 98% of the radioactivity chromatographed as alpha-cypermethrin, indicating that there was little or no isomerization in fat over an extended period of time. Lipophilic metabolite(s) of **alpha-cypermethrin**, with longer half-lives than that of the parent compound were, however, also present [redacted] 982a).

At 1 h after i.v. administration of **cypermethrin**, highest radioactivity levels were found in heart, liver, kidney, ovaries and blood, fat and skin region. Radioactivity was rapidly eliminated from blood with a half-life of 5.9 h. Similar half-lives were determined for most organs/tissues. Only in fat (>24 h) and skin backregion (12.8 h) longer half-lives were found. At 120 h, except for fat and skin region, all radioactivity levels were at or below 0.1 µg/g [redacted] 1993).
3 days after a single oral low dose of **cypermethrin** similar low concentrations as for alpha-cypermethrin were found for both sexes in kidney, muscle, brain and blood (<0.1%); male rat liver contained 3 times the amount found in the female liver. The residue in the fat of the female rats was 2-3 fold higher than that found in the male rats (0.31 for male and 0.72% for female) [redacted] 1977).
A comparison of the data at 3 days for the 2 groups of isomers revealed trans isomer was lesser retained in the tissue than the cis isomer. Between day 1 and day 8 after dosing the cypermethrin residues in liver, kidney, muscle, brain and blood decreased by a factor of 10. The highest and most persistent residual radioactivity was in fat. There was a trend to have lower concentrations of trans isomer than cis isomer; this was most noticeable in the fat of males (5 times lower trans than cis). There was a sex difference for the trans isomer in the fat with a 2.5 times higher level in females than in males ([redacted] 1977).
Seven days after dosing with 200 mg/kg **cypermethrin** very little radioactivity was retained by the animals (<1% of the administered dose). The concentration of radiolabelled material in the tissues were generally low, being less than 1 µg/g with the exception of tissues which were still actively engaged in the metabolism or which possessed a high fat content. The highest residues were found in fat, they were not 100 times higher than after 2 mg/kg [redacted] 980).

Distribution of cyclopropane- or phenoxybenzyl moiety among the different tissues appear to be comparable except in fat were the levels of benzyl moiety were somewhat higher. The extraction of label from tissues with solvent was well above 50% for most tissues (e.g. fat 99%) except for liver (27-48%) [redacted] 980).

Repeated dose study

The following information was taken from the DAR of zeta-Cypermethrin:
The concentration of radioactivity found in tissues of male and female rats after the last of 28 daily oral doses of ^{14}C labeled on the benzyl ring **cypermethrin** showed a similar distribution in male and female rats with the exception of gonads. The highest concentrations of radioactivity were found in fat and tissues with a high fat content i.e. adrenal glands, skin and ovaries. High concentrations were also found in organs associated with absorption (GI tract), metabolism (liver) and excretion (kidney), while lower concentrations were found in whole blood and plasma. All other tissues studied, notably the brain, contained little or no radioactivity. The residual carcass also contained a considerable quantity of radioactivity due at least in part to the remaining adipose tissue and skin [redacted] 1980).

Further information was taken from the DAR of alpha-cypermethrin, without Tables:
When given as a low daily dose over 70 days, **cypermethrin** related radioactivity at day 70 was found predominantly in lipid sites, particularly adipose tissue and skin. In fat the cis isomer represented 88% of the residue, the trans isomer 12%. The cis and trans isomers were eliminated with elimination half-lives of 18.24 and 3.43 days, respectively, to reach background levels 7 weeks after stop of dosing [redacted] 1981).

From the open literature it appears that more rapid elimination of trans **cypermethrin** is not due to a difference in lipophilic character, but is more probably related to a lipase mediated hydrolysis of the ester bond which would be expected to proceed much more rapidly with the trans isomer than with the cis isomer.

Metabolism (taken from DAR alpha-cypermethrin, 1999, except where mentioned otherwise)
The metabolic fate of **alpha-cypermethrin** is similar to that of cypermethrin. Hydrolytic cleavage of the ester bound and elimination of the cis and trans cyclopropanecarboxylic acid moieties in the free and conjugated form is a major route of metabolism of cypermethrin in rats and in man.
Metabolism of **cypermethrin** and elimination of metabolites derived from the cyclopropane carboxylate moiety via urine in man was rapid (Eadsforth, 1981). From open literature it seems that the much less toxicity of the trans isomer as compared to the cis isomer of cypermethrin is largely owing to the facile metabolism of the trans-compounds by carboxylesterase-catalysed hydrolysis [redacted] 1991).

The cis and trans cyclopropanecarboxylic acid moiety were almost exclusively conjugated and rapidly eliminated as the ester glucuronide (30% of the dose in male, 47% of the dose in females; trans representing 51.4% and cis 32.8% of the administered dose) with some free acid (twice as much trans as cis) being found in the urine (4%) together with traces of the trans-hydroxymethyl cyclopropyl acids (2%).

Minimal hydroxylation occurred at the methyl groups attached to the cyclopropane ring, giving a complex mixture of partially unstable metabolites. The cis isomer, somewhat more resistant to hydrolysis than the trans isomer, gave more hydroxylated metabolites than did the trans isomer. Only small amounts of hydroxylated metabolites with the ester bound intact (e.g. 4-HO-cis-cypermethrin) were excreted in the feces.

The **3-phenoxybenzyl product** was mainly converted into 3-phenoxybenzoic acid. 3-Phenoxybenzoic acid was excreted free but aromatic hydroxylation at the 4´-position occurred also before excretion followed by sulphation of 3-(4-hydroxyphenoxy)benzoic acid.
The 4´-hydroxy sulphate forms the major aryl metabolite (16% of the dose) with 3-phenoxybenzoic acid as the second most important (5%). The other identified aryl metabolites are 3-(4´-hydroxyphenoxy)benzoic acid (1%) and the glycine conjugate. N-(3-phenoxybenzoyl)glycine (1%).

There was no evidence of any major sex differences in biotransformation at the higher toxic dose, or of any dose-dependent major change in the route or extent of biotransformation, but a number of uncharacterized minor metabolites (generally <3% of the dose) were detected [redacted] 1980).

The **metabolic fate of 3-phenoxybenzoic acid (3PBA)** and one of its major plant metabolites, the glucoside conjugate, was studied in rats. Rats hydrolyse 3PBA-glucoside and further metabolise it as 3PBA. The metabolism of 3PBA administered as such to rats appears to be virtually identical to that of 3PBA liberated during the metabolism of cypermethrin ([redacted] 1978).
In the skins of rats receiving 3-phenoxybenzoic acid (after 7 daily oral doses giving a total of 750 mg/kg) unchanged 3-phenoxybenzoic acid and a mixture of 3-phenoxybenzoyl-dipalmitins were identified. The components were present in the approximate ratio 3:7. They were also present in the carcass, but in the ratio 9:1 [redacted] 1979).

Only small amounts of hydroxylated metabolites of cypermethrin with the ester bound intact (e.g. 4´-hydroxy-cis-cypermethrin) were excreted in the feces. The very low yield of radioactivity found in the bile was probably comprised of these compounds, and suggests that the cypermethrin found in the feces was there because it was not absorbed during passage through the gut. There is, as yet, no evidence for the metabolism at the 2,2.dichlorovinyl group of cypermethrin [redacted] 1978).

In mice, metabolism of **cypermethrin** was similar as in rats [redacted] 1981).

In vitro studies using liver microsomal preparations from rats and mice showed that ester cleavage is more extensive for trans than for cis pyrethroids, while the relative extent of oxidative metabolism of the 2 isomers depends on the enzyme source. The low toxicity of trans cypermethrin to mice to the corresponding cis isomers is consistent with their greater ease of biodegradation in the mouse microsomal system (Shono et al., 1979).

Human data

The following information on human data was taken from the DAR of zeta-Cypermethrin:

Following a single oral dose 3.3 mg **cypermethrin**, peak excretion rates of the hydrolysis products *cis* and *trans* DCVA are generally seen within the first 4 h. Peak excretion rates of oxidized metabolites 3PBA and 4OH3PBA were seen later between 4 and 24 h after dosing. An average of 93% of the metabolites recovered was excreted within 72 h of dosing. In the majority of individuals all or some of the metabolites were still detectable in urine 5 days after dosing. The mean elimination half-life for total metabolites was 16.5 h. The average trans/cis DCVA ratio was 2:1 and approximately equivalent amounts of total DCVA and total phenoxybenzoic acid metabolites were recovered in urine. Based on the recovery of *trans* DCVA the proportion of the administered dose absorbed is estimated to be between 27% and 57% (mean 36%).

Following a single dermal dose of 31 mg, metabolites were detectable in the majority of the urine samples collected for the period 0-4 h, but peak excretion rates were not seen until between 12 and 36 h after dosing. The mean elimination half-live for total metabolites was 13 h. The average *trans/cis* DCVA ratio was 1:1.2 and the amounts of cyclopropane acid metabolites were, on average, 4 times lower than the amounts of metabolites derived from the phenoxybenzyl moiety. Based on urinary excreted metabolites, dermal absorption reaches approximately 1.88% of the dose. These results demonstrate 2 important differences in the excretion of urinary metabolites when cypermethrin is dosed orally and dermally. First, the *trans/cis* DCVA ratio differs (oral 2:1; dermal 1:1.2) and secondly the ratio of total DCVA/phenoxybenzoic acid metabolites differs (oral 1:0.8; dermal 1:4). Therefore, monitoring of total DCVA could substantially underestimate absorption when dermal is the main route and the amount of 3PBA + 4OH3PBA will best reflect absorption of cypermethrin by all routes (Woollen et al., 1992; published study).

After a single oral dose cypermethrin (0.25-1.5 mg) to 4 human subjects, urine was monitored for the free and conjugated cyclopropane carboxylic acid. Urinary excretion during the first 24 h after dosing showed an average 78% of the *trans* isomer dose and 49% of the *cis* isomer dose in the form of metabolites. These results suggest that, as in other mammals, ester cleavage and elimination of the *cis* and *trans* cyclopropane carboxylic acid moieties is a major route of metabolism of cypermethrin in man (Eadsforth and Baldwin, 1983).

Excretion (taken from DAR alpha-cypermethrin, 1999, except where mentioned otherwise)

After oral administration of a single low or high dose of **alpha-cypermethrin**, 76-78% of the dose was excreted within 24 h (43-46% in urine and 30-35% in feces) reaching 93.1-95.6% in 4 days. Alpha-cypermethrin is eliminated similarly by both sexes [redacted] 1982 DocID AL-905-066).

After oral administration of a single low dose of **cypermethrin** excretion of radioactivity within 3 days was 90.8-100.8% (54.7-66.5% in urine, 28.7-27% in feces) ([redacted] 1977). Urinary excretion of the trans isomer appears to be faster while cis isomer was more excreted via faeces. Total recovery was 100% for male and 97% for female rats for the cis and 103% for males and 101% for females receiving the trans isomer in 3 days [redacted] 1977).

After oral administration of a high dose of cypermethrin, 73-79% of the dose for males and 80-87% for females was eliminated within 3 days. The excretion was generally greater in the feces than in the urine (except females dosed with ^{14}C-cyclopropyl) and suggests that an appreciable portion of the dose was not absorbed. Cyclopropyl label elimination was somewhat slower than that seen with the benzyl label. The benzyl label is more excreted in the feces than the cyclopropyl label ([redacted] 1980).

Detection of some radioactivity in expired air (0.1%) indicates some metabolic breakdown of the cyclopropyl ring.

Biliary excretion of metabolites was investigated and only 1-1.6% of an oral dose was excreted via this route within 4-5 h as conjugated metabolites in a ratio cis:trans of 5:3.

After intravenous administration of cypermethrin to female rats urinary excretion was somewhat lower than after oral administration.

Additional information taken from the DAR of zeta-cypermethrin (2008):
Cumulative radioactivity excreted in the urine amounted to 0.8%, 11.6%, 44.5% and 61.3% after 1, 4, 24 and 120 hours, respectively. Significant amounts of radioactivity (7.9%) were excreted via bile to feces from 4 to 24 hours, reaching 28.4% after 120 hr with the major amount (24.3%) excreted already within the first 48 hours. Total excreted radioactivity amounted, on average, to 89.7% [redacted] 1993).

Human data **(Taken from the DAR of alpha-cypermethrin)**
After single or repeated oral administration of **alpha-cypermethrin** (0.25-0.75 mg), people excreted 43 or 49% respectively of the dose in urine within 24 h after treatment in the form of free and conjugated cis cyclopropane carboxylic acid (van Sittert et al., 1985, DocID AL-445-003).
After a single oral dose of **cypermethrin**, urinary excretion was rapid and confined to the first 24 h sample collection period: 78% of the trans isomer and 49% of the cis isomer as free and conjugated cyclopropanecarboxylic acid (Eadsforth, 1981).

Excretion of plant metabolites in rats
After 3-phenoxybenzoic acid administration to rats the major route of excretion for both sexes was the urine (81.5% for males and 79.8% for females). After 4 days very little radioactivity was observed in the carcass and skin of either sex (0.7% males; 0.65% females).
Following oral dosing to rats of the glucoside derivative, the elimination of radioactivity was very similar to that found with 3PBA with the exception that only 0.3% of the dose was found in the skin [redacted] 1978).

Metabolism in livestock (Taken from the DAR of alpha-cypermethrin)
Alpha-cypermethrin:
^{14}C-labelled alpha-cypermethrin was administered orally to a cow (14 mg/kg) via twice daily doses added to the diet. Whereas muscle, fat and milk mainly contained a single compound with similar chromatographic properties to alpha-cypermethrin (muscle 85%, fat 91%, milk 97%), the liver extract contained at least 8 metabolites with a broad range of polarities, one component (±16%) had similar chromatographic properties to those of alpha-cypermethrin. In urine, the 2 major components were probably 3PBA (3%) [redacted] 1994).

Excretion of ^{14}C-labelled alpha-cypermethrin was rapid in lactating cows after a single oral administration at 0.1, 0.2, or 0.4 mg/kg bw reaching 48% in urine and 28% in stools in the first 24 h. The amount present in milk was 0.08 µg/mL on the 4th day ([redacted] 1990).

Cypermethrin:

Lactating cows were fed with cypermethrin; the insecticide is rapidly metabolized by cows. Urinary metabolites were tentatively identified as 3-(4-hydroxyphenoxy)benzoic acid O-sulphate (minor) and N-(3-phenoxybenzoyl)glutamic acid, the major metabolite. Part of the ingested cypermethrin (36%) was eliminated unchanged in the feces. The major residue in liver and kidney was N-(3-phenoxybenzoyl)glutamic acid. Unchanged cypermethrin was found in the lipophilic component of milk. Unlike rats, cows afford only small amounts of phenyl-hydroxylated metabolites in urine.Metabolites in the urine were the result of hydrolysis and the formation of 3-phenoxybenzoic acid, which was conjugated mostly with glutamic acid and to a lesser extent with glycine. The cows therefore differs from the other species studies in respect of the amino-acid selected for conjugation ([redacted] 1980; [redacted] 1976).

After dermal application to sheeps, absorption was slow and less than 0.5% of the dose was excreted in the urine in 24 h and only 0.5% was excreted in feces within 6 days. Conversely, absorption and elimination after oral treatment was rapid over 48 h (61%). Radioactivity in fat samples was identified as cypermethrin ([redacted] 1977).

The fate of cypermethrin was assessed in laying chickens. Unchanged compound was essentially recovered in yolk; minor metabolites were trans hydroxyl(methyl)-cypermethrin and 3-phenoxybenzoic acid. In fat unchanged cypermethrin was present. In liver beside unchanged cypermethrin polar metabolites which could not be converted chemically to 3PBA or 4HO-3PBA were detected ([redacted] 1982).

Metabolism in plants (Taken from the DAR of alpha-cypermethrin)

Under glasshouse conditions:

Metabolism of cypermethrin was studies in lettuce and cotton foliage under glasshouse conditions after treatment with separate cis- and trans-isomers. The detected metabolites (3-phenoxybenzoic acid, the amide and a hydroxylated derivative of the parent compound, 4´-hydroxy derivative?) suggests a metabolism by conversion of the cyano group to amide and by hydrolysis at the ester bond leading to the formation of 3-phenoxybenzoic acid. There was also evidence for aryl hydroxylation of the intact molecule (Gilham, 1976).

In cotton plants only minor variations in the rate of degradation of cypermethrin were observed: 3-phenoxybenzoic acid and 3-phenoxybenzyl alcohol were identified. The presence of polar metabolites formed by conjugation of the cyclopropane carboxylic acid was suggested. No evidence was provided to suggest that ether cleavage had occurred (Sherren and Dutton, 1981).

Soya bean plants has been treated by spraying of the plant; the major degradation pathway of cypermethrin appears to be hydrolysis of the ester bond of the parent molecule followed by conjugation of the metabolites produced. Small concentrations of metabolites with the ester bond intact were also observed. The concentrations of free metabolites observed were considerably less in soya compared with cotton and lettuce (Edwards,1979).

Using soybean callus tissue cultures the metabolites which were detected are consecutive to the hydrolysis at the ester linkage and oxidation of one of the methyl groups attached to the cyclopropyl ring (Standen, 1980).

Under outdoor conditions
The major metabolite detected in lettuce foliage was the cyclopropane carboxylic acid, which occurred mainly as conjugates with sugars including glucose. Relatively few components have been detected apart from cypermethrin and material of quite high polarity and contrasted to the previous indoor study. The major metabolites of cypermethrin in lettuce under outdoor conditions resulted from ester cleavage and further metabolism or conjugation of the acid and alcohol moieties (Wright, 1977).
Cis and trans isomers of cypermethrin were applied as overall sprays to cotton plants. The major metabolites present in boll cares and leaves were cis- and trans-cyclopropanecarboxylic acids and 3-phenoxybenzoic acid, which all occurred in both free and conjugated forms. In the kernel small radioactive residues occurred as metabolites, which it was not possible to identify (Hitchings and Wright, 1979).
The leaves of apple trees contained unchanged insecticide (36-42%) and the apple peel contained 50-77% of unchanged insecticide. In leaves and fruits treated with cis isomer there had been considerable conversion into trans isomer. There was no conversion into the cis isomer. Metabolites detected in leaves and fruits were cis, trans cypermethrin, 3-phenoxybenzaldehyde, 3-phenoxybenzoic acid, the amide, the hydroxylated amide, 3-phenoxyalcohol and conjugated material (Dutton and Roberts, 1978).

Conclusion: (Taken from the DAR of alpha-cypermethrin)
Absorption of **alpha-cypermethrin** in rats within the first 24 h after oral administration represents approximately 45% of the dose (43-46% in urine and 30-35% in feces) 76-78% of the dose was excreted within 24 h reaching 93.1-95.6% in 4 days. Increasing the dose by a factor of 10 did not modify the excretion.

The absorption of cypermethrin after oral low dose represents approximately 50% of the dose (32-62% in urine; 16-35% in feces) within the first 24 h after administration; 2-3 days later 90-100% of the dose was recovered in excreta (54.7-66.5% in urine as unchanged compound and metabolites and 28.7% in feces mainly as unchanged compound). After high dose administration, absorption of cypermethrin was reduced to 8% (7-19% of the dose is excreted in urine while 7-31% is recovered in feces) suggesting a saturation effect at high dose.
After dermal application to human skin 28% of cypermethrin was retained into the skin within 4h.

Alpha-cypermethrin reached maximal tissue concentrations within 24 h after administration decreasing rapidly within 4 days after administration (<0.01%). Appreciable quantities of test material were present in fat (3.64 µg/g tissue at 24 h), decreasing slowly as a function of time (0.83 µg/g tissue after 7 days).
One hour after i.v. administration of cypermethrin radioactivity was found in heart, liver, kidney, ovaries and blood, fat and skin region. Low tissue concentrations were found (<0.1%) 3 days after oral administration of cypermethrin. Trans isomer was less retained (5 times lower trans than cis) and there was also a sex difference for the trans isomer in the fat 2.5 times higher level in females than in males.
The extraction of label from tissues with solvent was well above 50% for most tissues (e.g. fat 99%) except for the liver (27-48%). Tissue retention of the phenoxybenzyl moiety in fat is slightly higher than cyclopropyl moiety.

The half-life values for elimination of cis and trans isomers were calculated to be 18.24 and 3.43 days showing that cis and trans isomers of cypermethrin accumulated in fat. In contrast, the reduction of radioactivity in the liver and kidney with time is very rapid and after 2 weeks is at or below the limit of detection.

The metabolic fate of alpha-cypermethrin is similar to that of cypermethrin; the ester bound is preferentially cleaved yielding a cyclopropane carboxylate moiety and a dibenzyl (3-phenoxybenzoic acid) moiety. A more facile metabolism of the trans compounds by carboxylesterase-catalysed hydrolysis was reported in mammals. The phenoxybenzoic acid compounds is further hydroxylated and half of the administered dose of cypermethrin or alpha-cypermethrin is recovered as 4-OH-3-phenoxybenzoic acid of which 65% is the sulfate conjugate and to a minor percentage the glycine conjugate. The unchanged compound is also found as glucuronide and sulfate conjugate. In feces, most of the radioactivity is unchaged compound; radioactivity as metabolites represents only 1 to 3% of the administered dose. There is, as yet, no evidence for the metabolism at the 2,2-dichlorovinyl group of cypermethrin.

In humans, urinary **excretion of alpha-cypermethrin** reached 43 to 49% within 24 h after a single or repeated oral administration. After a single oral dose of cypermethrin urinary excretion reached 49% for the cis isomer and 78% for the trans isomer in 24 h after dosing. These data suggest that human absorption of cypermethrin is comparable to rats. Metabolism was also similar to rats. The presence of the trans isomer does not influence the metabolism and excretion of its cis congener.
Metabolites of cypermethrin were identified in mice and cows. Overall, metabolism is similar to rats. Differences that occur are related to the rate of metabolite formation rather than to the nature of the metabolites formed. The only major differences between species relate to conjugation reactions. While the fate of the cyclopropanecarboxylic acid has bennn shown to be largely independent of species, the fate of the 3-phenoxybenzyl moiety, however, is species dependent, with marked differences either in the extent of aromatic hydroxylation or in the amino acid utilized for conjugation of the carboxylic acid.
Ester cleavage also takes place in plants. The phenoxybenzyl and cyclopropyl moieties are readily converted into glucoside conjugates.

Alphacypermethrin (CL 900049): Absorption, distribution, excretion, and pharmacokinetics of orally administered (benzyl-ring-14C)CL 900049 in the rat
AL-440-017
Guidelines: <none>
GLP: yes (It is stated in the report that the study was conducted in compliance with GLP Standard. Quality assurance statement is attached. GLP certificate of the competent aurhority is missing.)
Remark: This study is investigating oral absorption kinetics and bile excretion of alpha-cypermethrin. Furthermore the optical conversion of alpha-cypermethrin in vivo

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alphacypermethrin (BAS 310 I)

Description:	white-light yellow crystalline solid		
Batch/purity #:	Radiolabeled (^{14}C):	CP-2386	98%
	Radiolabeled (^{14}C):	CFQ11156	92%
	Nonlabeled:	351	purity not given
Stability of test compound:	To demonstrate the stability of the test item in the application formulation, HPLC analysis of the application formulation was performed.		

2. Vehicle and/or positive control: corn oil

3. Test animals:

Species:	Rat
Strain:	SD (Crj; CD) (Charles River Japan, Inc.)
Age:	7 weeks
Sex:	males and females
Number of animals:	61 males and 32 females
Weight at dosing:	males: 182.3 – 237.3 g Females: 142.3 – 175.9 g
Acclimation period:	at least 5 days
Diet:	diet for rodent (MF, Oriental Yeast), *ad libitum* Prior to administration rats were fasted about 16 hours before administration and fed at 4 hours after administration.
Water:	Tap water *ad libitum*
Housing:	During acclimatization four animals per cage (designed by DPC), then individually in restraining Bollman cage (designed by DPC)

Environmental conditions:

Temperature:	21 – 25°C
Humidity:	Animal experimental facility: 45 – 65% Experiment facility IV: 40 – 70%
Photoperiod:	Alternating 12-hour light and dark cycles

4. Preparation of dosing solution

Unpurified ^{14}C-alphacypermethrin (batch: CFQ11156) and unlabeled alphacypermethrin were weight out and dissolved in designated amount of corn oil to prepare 0.4 mg alphacypermethrin/mL dosing formulation.

The purified 14C-alphacypermethrin (batch: CP-2386) in ethyl acetate solution was collected, weighed unlabeled alphacypermethrin was added and ethyl acetate was removed by nitrogen gas. The residue was dissolved in the designated amount of corn oil to prepare 0.4, 4 and 7 mg alphacypermethrin/mL dosing formulation.

After preparation, the dosing formulations were stored at approximately 4°C in the dark until use.

In order to demonstrate the stability of the test item in the application formulations, confirm the identity and determine the isotope pattern, HPLC analysis was performed. For all dose groups, diluted application solutions were LSC (liquid scintillation counter) measured and the measured values were taken for calculation. The radiochemical purity of 14C-alphacypermethrin (batch CFQ11156) was as low as 92% before the first use. Therefore, the test substance was purified after administration in the two preliminary studies. The radiochemical purity was 92% after completion of the two preliminary studies. The radiochemical purity of 14C-alphacypermethrin (batch CP-2386) was 98% or more throughout the study period, indicating no decrease in the purity. The total radiochemical purity of cis 1 and cis2 was 98% or more.

Aliquots of the formulated test item were administered to the rats by gavage. The actual applied doses were 2, 20 and 35 mg/ 5 mL/kg bw.

B. STUDY DESIGN AND METHODS

1. Dates of work: November 16, 1999 – March 27, 2000

Two preliminary studies were conducted in order to determine the radioactivity concentrations in plasma, the excretion of radioactivity in urine, feces and expired air and residual radioactivity in carcass.

In four experiments of the definitive study the radioactivity concentrations in plasma and tissues, excretion of radioactivity in urine, feces and bile and the residual radioactivity in carcass was determined.

Each group consisted of four animals excluding preliminary study (one animal).

Determination of radioactivity concentrations in plasma:
After single oral administration of ^{14}C-alphacypermethrin to male and female rats at doses of 2 and 20 mg/mg bw, blood was withdrawn at the designated time from the tail vein using a heparinized micropipette into a microtube containing heparin. The sampling times were 30 minutes, 1, 2, 4, 6, 8, 10, 12, 24, 48, 72, 120 and 168 hours after administration. The radioactivity in the sample was measured in the LSC.

Determination of excretion of radioactivity in urine and feces, and residual radioactivity in carcass:
Male and female rats were housed in metabolic cages after single oral administration of ^{14}C-alphacypermetrin at doses of 2 and 35 mg/kg bw. Urine and feces were collected at the defined times and the excretion ratios of radioactivity in the urine and feces were determined. The sampling times were 0-4, 0-8, 0-24 hours and every 24 hours up to 168 hour for urine, and were every 24 hours up to 168 hours for feces. The expired air was not collected because the excretion of radioactivity in the expired air was not found in the preliminary study. The excretion of radioactivity in the urine and feces and the residual radioactivity in the carcass were determined by LSC. Urine samples up to 48 hours after administration were collected on an ice bath in the dark and stored at -20°C for investigation of quantitative analysis of isomers in urine except the samples of radioactivity. The feces recovered at every sampling time were brought to 300 mL with 50% methanol and homogenized and the radioactivity was counted in LSC. After the urine and feces collections at 168 hours after administration, the rat was sacrificed by ether overdose. The carcass was solubilized in 500 mL of 0.5 mol/L sodium hydroxide and 30 mL of toluene by heating with reflux. The radioactivity was counted in LSC.

Determination of excretion of radioactivity in bile:
Male rats were anesthetized with ether and their common bile ducts were cannulated with polyethylene tubes for bile collection. The animals were dosed orally with ^{14}C-alphacypermetrin at doses of 2 and 20 mg/kg bw after recovery from anesthesia. Bile, urine and feces were collected at the defined times, and excretion ratios of radioactivity in bile, urine and feces were determined. The sampling times were 0-2, 0-4, 0-6, 0-8, 0-24 and 0-48 hours after administration for bile. The sampling times of urine were 0-4, 0-8, 0-24 and 0-48 hours after administration. The sampling times of feces were 0-24 and 0-48 hours after administration. The final sampling time for the group 11 was limited to 24 hours after administration.
After dilution of the obtained bile, urine and feces the radioactivity was counted in the LSC. The gastro-intestinal tract and contents were collected at 24 hours or 48 hours after administration. The radioactivity of the carcass and the gastro-intestinal tract was determined after solubilization by LSC.

Determination of radioactivity concentrations in tissues:
After single oral administration of ^{14}C-alphacypermetrin at doses of 2 and 20 mg/kg bw male and female rats were housed in animal cages. The male rats (2 and 20 mg/kg bw) at 6, 24 and 168 hours after administration and the female rats (2 mg/kg bw) at 8, 24 and 168 hours after administration were sacrificed by exsanguination from the abdominal aorta under ether anesthesia using vacuum tubes containing heparin. The following tissues were excised: plasma, blood, cerebrum, cerebellum, pituitary gland, spinal cord, eyeball, Harderian gland, thyroid gland, trachea, mandibular gland, thymus, heart, lung, liver, kidney, adrenal gland, spleen, pancreas, fat (around the kidney), brown fat, skeletal muscle (from the femoral region), skin (from the axillary region), bone marrow, aorta, mesenteric lymph node, testis (male), epididymis (male), prostate gland (male), ovary (female), uterus (female), stomach, small intestine, large intestine and urinary bladder.
The radioactivity in each sample after preparation was counted in LSC in order to determine the concentrations and distribution of the radioactivity in the tissues.

Quantitative Analysis of Isomers in Urine:
The relative amounts of optical isomers *(cis 1, cis 2, trans* 3 and *trans* 4) in 0-48 hr urine collected from the 2 and 20 mg/kg male rat groups, and the 2 mg/kg female rat group were analyzed by LSC to determine the quantitative extraction ratio of radioactivity in an ethyl acetate and the water layer separately. The obtained layers were then investigated for the different optical isomers via HPLC-RAD in each sample. The collected urine, which was not analyzed soon, was stored at -20°C.

II. RESULTS AND DISCUSSION

Stability and homogeneity control analysis of the test substance preparation
The analytical investigations of 14C-Alphacypermethrin demonstrated the stability and homogeneity of the test substance in the preparation during the period of administration.

Radioactivity concentrations in plasma (see Table 5.1.1-3):
After oral administration of a 2 mg/kg bw dose to male rats, the radioactivity concentration in the plasma reached a maximum of 1268 ppb at 6 hours and then declined biphasically with a half-life of 3.8 and 21 hours. The AUC (0-∞) was 13398 ng eq. hr mL^{-1}, respectively. The C_{max} and AUC (0-∞) of the 20 mg/kg bw dose group were 5.1 and 8.5 times those in the 2 mg/kg bw dose group, respectively. The C_{max} and AUC (0-∞) both increased but the increase was smaller than the increase in the dose level. The half-lives were longer than those in the 2 mg/kg bw dose group.
After single oral administration of ^{14}C-alphacypermetrin to female rats at dose of 2 mg/kg bw, the radioactivity concentration in the plasma reached C_{max} of 1491 ppb at 7 hours, and then declined with a half-life of 3.9 hours from 8 to 24 hours and a half-life of 24 hours after 24 hours. The AUC(0-∞) was 18336 ng eq. hr mL^{-1}. The AUC(0-∞) was larger than in male rats at the same dose level but there were no large differences in the t_{max}, C_{max} and half-lives. The C_{max} and AUC(0-∞) of the 20 mg/kg bw dose group were 5.0 and 6.0 times those in the 2 mg/kg bw dose group, respectively. The C_{max} and AUC(0-∞) both increased but the increase was smaller than the increase in the dose level.

Data are expressed as the mean values ± S.D. of four animals
N.D.: Not detected

At tmax the variability of radioactivity in the plasma in the low dose group differed by a factor of 2.6 and 1.5, and in the high dose by a factor of 1.2 and 1.7 in male and female rats, respectively, indicative for the range of inter-individual variability of alpha-cypermethrin toxicity in studies with bolus dosing.

Excretion of radioactivity in urine, feces, and residual radioactivity in carcass (see Table 5.1.1-4):
After single oral administration of ^{14}C-alphacypermetrin to male rats at a dose of 2 mg/kg bw, the excretion of radioactivity in the urine was 31.8%, 34.9% and 36.1% of the dose up to 24, 72 and 168 hours, respectively. The excretion of radioactivity in the feces was 55.6%, 61.6% and 62.5% of the dose up to 24, 72 and 168 hours after administration, respectively. The total excretion of radioactivity in the urine and feces was 98.5% of the dose up to 168 hours after administration. The residual radioactivity in the carcass was 1.3% of the dose at 168 hours after administration. In the 35 mg/kg bw dose group the total excretion of radioactivity in the urine and feces was 96.5% of the dose up to 168 hours after administration. The residual radioactivity in the carcass was 1.5% of the dose at 168 hours after administration. As compared with the results in the 2 mg/kg bw dose group, the excretion of radioactivity in the urine was lower by 7.5% of the dose and the excretion of radioactivity in the feces was higher by 5.4% of the dose.

Comparing these results with the female rats at the 2 mg/kg bw dose level, the excretion of radioactivity in the urine was higher by 12.0% of the dose and the excretion radioactivity in the feces was lower by 14.2% of the dose. Comparing the 2 mg/kg bw dose group with the 35 mg/kg bw dose group of the female rats, the excretion of radioactivity in the urine was lower by 13.8% of the dose and the excretion of radioactivity in the feces was higher by 11.9% of the dose.

-: Not determined

The single animal data after oral administration of alpha-cypermethrin at a dose of 2 mg/kg bw shows significant variability: after 168 hours the excretion via urine ranged in the low dose males between 29.4 % and 44% of the administered dose, whereas in females the excretion ranged from 41.8% up to 57%. The amount considered bioavailable (excretion via urine plus carcass) range between 30.3-45.4% of the dose administered in males and 42.7 – 58.2% of the dose in females [see Table 5.1.1-5].

Table 5.1.1-5: Individual bioavailability of alpha-cypermethrin in the low dose group based on excretion via urine and amount in carcass [amount of radioactivity in % of administered dose]

Excretion of radioactivity in bile of male rats (see Table 5.1.1-6):
After single oral administration of ^{14}C-alphacypermetrin to male rats at a dose of 2 mg/kg bw, the excretion of radioactivity in the bile was 1.6%. 2.6% and 3.0% of the dose up to 8, 24 and 48 hours, respectively. The excretion of radioactivity in the urine was 1.7%, 3.0% and 3.4% of the dose up to 8, 24 and 48 hours after administration, respectively. The excretion of radioactivity in the feces was 65.0% and 71.5% of the dose up to 24 and 48 hours after administration, respectively. At 48 hours after administration, the ratios of radioactivity in the gastro-intestinal tract and contents were 0.4% and 3.2% of the dose, respectively. The residual radioactivity in the carcass after removing the gastro-intestinal contents was 15.3% of the dose. Looking at the 20 mg/kg bw dose group with male rats, the excretion of radioactivity in the bile and urine was comparable with that in the 2 mg/kg bw dose group. The excretion of radioactivity in the feces was 46.8% and 56.3% of the dose up to 24 and 48 hours after administration, respectively. At 48 hours after administration, the ratios of radioactivity in the gastro-intestinal tract and contents were 0.6% and 12.4% of the dose, respectively. The residual radioactivity in the carcass after removing the gastro-intestinal contents was 21.7% of the dose.
After single oral administration of ^{14}C-alphacypermetrin to male rats at a dose of 2 mg/kg bw, the excretion of radioactivity in the bile and urine collected up to the final sampling time of 24 hours was comparable with that in the group determined up to 48 hours after dosing. The excretion of radioactivity in the feces was 72.3% of the dose up to 24 hours after administration. At 24 hours after administration, the ratios of radioactivity in the gastro-intestinal tract and contents were 0.5% and 9.9% of the dose, respectively. The residual radioactivity in the carcass after removing the gastro-intestinal contents was 8.8% of the dose.

Data are expressed as the mean values ± S.D. of four animals
-: Not determined

Bile excretion accounts for around 3% within the first 24 hours of excretion.

Radioactivity concentration in tissue (see Table 5.1.1-7):
At 6 hours after administration of 2 mg/kg bw test substance to male rats, the radioactivity concentration in the mesenteric lymph node was the highest, being 1.78 times that in the plasma (1255 ppb). The radioactivity concentrations in the other tissues were comparable with or lower than that in the plasma. indicating low tissue distribution at an early time after administration. The radioactivity concentrations in the eyeball, cerebellum, spinal cord and cerebrum were 4-3% of that in the plasma, indicating that the distribution is especially low in these tissues. At 24 hours after administration, the radioactivity concentrations in the brown fat and fat showing a maximum concentration were the highest, being 9.85 and 8.89 times that in the plasma (81 ppb), respectively. The radioactivity concentrations in the tissues except the fat decreased. At 168 hours after administration, the radioactivity concentration in the fat was the highest, being 157 ppb. The radioactivity concentration in the brown fat (27 ppb), mesenteric lymph node (23 ppb), skin (12 ppb) and epididymis (10 ppb) were next high in that order. The radioactivity concentration in the fat was relatively high but decreased to 22% of the 24-hour value, suggesting that the elimination of radioactivity was slightly slower than that from the other tissues. The results from the 20 mg/kg bw dose group showed similar results.
The radioactivity concentration in the tissues in female rats showed a similar tendency to those in male rats as the radioactivity concentration in the mesenteric lymph node was the highest at an early time and the radioactivity concentration in the fat was high at 168 hours after administration. These results suggest no definite sex difference.

Quantitative Analysis of Isomers in Urine:
As the result of quantification of the isomers in the urine after administration of a 20 mg/kg bw dose, a radioactivity peak was observed only at the retention time of cis 2, suggesting that the optical conversion did not occur or occurred a little in vivo. Dosing with 2 mg/kg bw no radioactivity peaks were observed at retention times of isomers.

III. CONCLUSION

Absorption: After oral administration the radioactivity concentration in the plasma reached a maximum at 6-9 hours after administration and then declined biphasically with a half-time of 3.8 and 21 hours. After single oral application in rat between 34% and 46% of the dose is excreted within 48 hours via urine in male and female rats. After 168 hours 50 % is considered an adequate value for absorbed dose based on urinary excretion (29.4-57%), bile excretion (around 3%) and residual carcass radioactivity (around 1%).

Excretion: More than 92% of the radioactivity is excreted within 48 hours of administration, equally partitioned amongst feces and urine in females (both 46%) and slightly less in urine in males (34.2% via urine and 60% via feces). Excretion via bile is considered to be limited to around 3% in the first 24 hours. No radioactivity was excreted in the expired air. The new data are considered to confirm and supplement the originally presented data in the DAR.

Distribution: The highest radioactivity concentrations are found in well perfused organs (mesenteric lymphnode, kidney and liver) as well as in fat with the slowest elimination rate compared to the other tissues.

Quantification of isomers in urine: In the high dose group a radioactivity peak was observed only at the retention time of cis 2, therefore it is assumed that optical conversion did not occur or occurred only a little in vivo.

Metabolism of 14C-alpha-Cypermethrin (BAS 310 I) after oral administration in rats
2013/1086630
Guidelines: EPA 870.7485, EPA 860.1000: EPA Residue Chemistry Test Guidelines, MAFF Testing Guidelines for Toxicology Studies: Metabolism Animals (Japan), OECD 417, EEC 87/302 B
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: Alpha-cypermethrin (BAS 310 I)
Lot/Batch #: 775-0401 (benzyl-U-^{14}C)
1025-1034 (phenoxy-1,2,3,4,5,6-^{13}C)
986-1046 (cyclopropane-1-^{14}C)
990-1024 (cyclopropane-1-^{13}C)
L80-24 (unlabeled)
Purity: 96.1% (benzyl-U-^{14}C)
95.1% (phenoxy-1,2,3,4,5,6-^{13}C)
98.2% (cyclopropane-1-^{14}C)
97.7% (cyclopropane-1-^{13}C)
99.4% (unlabeled)
CAS#: 67375-30-8
Development code: 4078193
Stability of test compound: Stable during dosing period

2. Vehicle and/or positive control: The vehicle used was corn oil

3. Test animals

Species: Rat
Strain: Wistar (Crl:WI(Han), Charles River Laboratories, Germany)
Age: 7 weeks (arrival) / 8-9 weeks (administration)
Sex: Male and female
Number of animals: 40 (10 males + 10 females for each label)
Weight at dosing: 154-293 g
Acclimation period: 7-14 days
Diet: Kliba lab diet for mouse and rat, *ad libitum*
Water: Tap water *ad libitum*

Husbandry:	In accordance with the German Animal Welfare Act
Housing:	During acclimatization in groups in Macrolon Cages, then individually in Plexiglas metabolism cages
Environmental conditions:	
Temperature:	19-23°C
Humidity:	45-60%
Air changes:	>30 changes/h
Photoperiod:	Alternating 12-hour light and dark cycles

4. Preparation of dosing solutions

For oral administration of the test item, mixtures of ^{14}C labeled, ^{13}C labeled and unlabeled BAS 310 I were weighed in (in ratios of approximately 1:1:1) and suspended in corn oil. Aliquots of the resulting application formulations were subjected to MS analysis for identity check and for determination of the isotope pattern.

The test items used during the present metabolism study were ^{14}C-labeled either in the benzyl ring (benzyl label) or in the cyclopropane moiety (cyclopropane label). The benzyl-U-^{14}C-radiolabeled test item was mixed with phenoxy-1,2,3,4,5,6-^{13}C-BAS 310 I and unlabeled ^{12}C-BAS 310 I, while the cyclopropane-1-^{14}C radiolabeled test item was mixed with cyclopropane-1-^{13}C-BAS 310 I and unlabeled BAS 310 I prior to application in order to facilitate analysis by radio-HPLC and mass spectrometry.

B. STUDY DESIGN AND METHODS

1. Dates of work: October 24, 2011 – September 5, 2014

The treated rats consisted of an oral single dose group (10 rats/sex/label, about 20 mg/kg bw). All animals received the oral dose administered via gavage.

Six hours after administration of the test item, blood samples were taken and centrifuged to separate plasma from blood cells. In the case of female dose group (cyclopropane label), no sufficient blood samples could be obtained.

Urine of all dose groups was collected after 6, 12, 24, 48, 72, 96, 120, 144, 168 and 192 hours (female dose group, benzyl label: 190 h). Feces were collected in intervals of 24 hours up to eight days. After sampling, urine and feces were combined per sampling interval (several animals per dose group) and stored at -18°C or below.

In the case of male dose group (cyclopropane label), two animals had to be sacrificed prior to the first sampling. The other animals were killed 192 hours after administration (female dose group, benzyl label: 190 h). Blood was collected from the sacrificed animals and centrifuged to separate plasma from blood cells. Combined plasma samples (several animals per dose group) as well as combined samples of the cage wash and of liver, kidney and carcass were stored in a freezer at -18°C or below.

Samples were analyzed for total ^{14}C-radioactivity by samples combustion and/or liquid scintillation counting (LSC). Metabolite identification was performed by mass spectrometry and quantitative analysis using HPLC.
The radioactive residues were determined in urine and feces in time intervals of 24 hours for a total of eight days after administration (for urine samples additionally after 6 h and 12 h), as well as in cage wash. Subsamples of homogenized feces were extracted with acetonitrile and water. Urine samples of all time intervals and extracts from feces collected in the time intervals of 0-24 h and 24-48 h were analyzed by HPLC with radio detection.

II. RESULTS AND DISCUSSION

Storage stability
The analytical investigations performed within the present study demonstrated the specific radioactivity, purity, stability and homogeneity of ^{14}C-BAS 310 I in the vehicle for the performed experiments.

Balance and Absorption
The mean total recovery of radioactivity was 104.9% and 93.5% (benzyl label) or 87.6% and 91.0% (cyclopropane label) of the administered dose for male and female rats, respectively.
Approximately half of the administered dose was found as unchanged parent compound in feces extracts for each gender and both labels. Thus, alpha-cypermethrin was either only partly absorbed or only partly metabolized in the rat (sum of biotransformation products in urine and feces: approximately 31-39% of the dose). The unchanged parent molecule BAS 310 I was only detected in feces samples (portions of 39-57% of the dose).

Distribution
No tissues were examined during this study.
The cage wash contained 2.8% and 2.7% (benzyl label) or 2.4% and 2.3% (cyclopropane label) of the radioactivity administered for male and female rats, respectively.

Excretion
Excretion via urine and feces was nearly complete within 72-96 h after administration for both dose groups and both labels, with higher portions of radioactive residues in feces. Within the investigation period of eight days, total excretion of radioactive residues via feces amounted to 58-77% of the dose. Portions of approximately 25% of the administered dose were excreted via urine within eight days for each gender and both radiolabels. In the cage wash, portions of 2-3% of the dose were recovered. No significant differences in the excretion pattern related to gender or label were observed.

Table 5.1.1-8: Excretion of radioactivity via urine and feces after single oral administration of ^{14}C-BAS 310 I to rats at a dose level of nominally 20 mg/kg bw (group mean values)

1 168 – 190 h or 0 – 190 h or 6 h and 190 h, respectively, in the case of female dose group (benzyl label)

2 The values for this dose group represent portions compared to the test item administered to the eight animals from which the samples were obtained (animals M04 and M10 of dose group DXM, cyclopropane label, had to be sacrificed prior to the first sampling)

3 The % dose value for feces of male dose group, cyclopropane label, time interval of 0 to 24 h, and in consequence the subtotal feces and the total residues, are probably underestimated since the weight of the homogenized workup sample was significantly lower compared to the sample weight documented for the respective storage sample, and no unusually high loss was apparent during homogenization, suggesting that the actual sample weight of the storage sample was lower and the % dose value was actually higher, correspondingly

n.r. Not reported

Extractability

Extractability of radioactive residues of BAS 310 I in feces of male and female rats was high to very high, with 77.5-96.9% of the total radioactive residues extracted. The main portions of radioactive residues were extracted with acetonitrile (46.5-95.0% TRR), and lower portions were subsequently extracted with water (1.9-31.1% TRR). No significant differences in the extraction efficiency related to gender or label were observed.

Table 5.1.1-9: Extractability of feces samples with solvents (acetonitrile, water) after dosing of rats with [benzyl-U-^{14}C]- or [cyclopropane-1-^{14}C]-alpha-cypermethrin

Metabolism

Transformation mainly proceeds via cleavage of the ester, loss of the nitrile group and oxidation to form two carboxylic acid cleavage products, metabolites M310I001 and M310I011. These cleavage products and their derivatives are only detectable with the respective radiolabel. In urine, only label-specific cleavage products were detected which is probably due to the high molecular mass of the uncleaved molecule. Metabolite M310I001 can be conjugated with glucuronic acid to form the main component detected in urine (cyclopropane label), metabolite M310I004 (approximately 17% of the dose in sum of the time intervals for each gender). Hydroxylation of metabolite M310I001 at one of the methyl groups at the cyclopropane ring and conjugation with glucuronic acid produce the metabolites M310I003 and M310I002 found in urine at minor concentrations. Metabolite M310I011 can be hydroxylated to form metabolite M310I013 and then conjugated to the sulphate metabolite M310I014, the main component detected in urine (benzyl label, 16-17% of the dose). Conjugation of the carboxyl group of metabolite M310I011 and M310I013 with glycine forms the metabolites M310I010 and M310I012, respectively, which were only detected in urine at minor concentrations. The metabolites M310I001, M310I003, M310I011 and M310I013 were detected in urine and in feces extracts.

A further metabolic reaction is hydroxylation of the phenoxy ring of the molecule, forming metabolite M310I017, the main conversion product detected in feces extracts (1.3-2.5% of the dose in sum of the period of 0-48 h). Additional hydroxylation of one of the methyl groups at the cyclopropane ring produces metabolite M310I015. Cleavage of the ether bridge (loss of the phenyl ring) forms metabolite M310I016. Metabolites M310I017, M310I015 and M310I016 still contain each of the radiolabels. The label-specific metabolites M310I001, M310I003 and M310I013 may also be formed by analogous cleavage of the ester bond in metabolite M310I017 and M310I015. Up to 19 further peaks (per sample) in the chromatograms were characterized by their chromatographic properties (each below 1% dose for the analyzed time periods), including two assigned peaks in feces extracts for which molecular masses were determined.

Enantiomer-specific HPLC analysis (chiral column) of the parent fraction isolated from an exemplary acetonitrile extract of feces from male rats (cyclopropane label, 24-48 h) revealed no noticeable change in the ratio of the two enantiomers of alpha-cypermethrin compared to the administered racemic mixture and thus no indication that one enantiomer of alpha-cypermethrin was preferably metabolized in rats.

III. CONCLUSION

Excretion via urine and feces was nearly complete within 72-96 h after administration for both dose groups and both labels, with higher portions of radioactive residues in feces. In the cage wash, portions of 2-3% of the dose were recovered. No significant differences in the excretion pattern related to gender or label were observed.
In comparison, urine and feces extracts from male and female rats showed qualitatively and quantitatively similar metabolite patterns. The experiments with the two radiolabels indicate that only cleavage products of BAS 310 I are excreted via urine. Hydroxylation and / or conjugation (with sulphate or glycine in the case of the benzyl label, with glucuronic acid in the case of the cyclopropane label) occur with both parts of the molecule. The quantitative distribution of the uncleaved components in feces (hydroxylated metabolites and derivative with the phenyl ring lost) was very similar for both labels.

Figure 5.1.1-1: Proposed metabolic pathway of BAS 310 I in rats

According to the new data requirements for active ingredients of plant protection products as set out in Commission Regulation (EU) No. 283/2013 (1 March 2013, OJ L93, 1ff, 3.4.2013), "comparative *in vitro* metabolism studies shall be performed on animal species ... and on human material ...in order to determine the relevance of the toxicological animal data and to guide in the interpretation of findings and in further definition of the testing strategy..." (Section 5, Toxicological and metabolism studies, point 5.1.1., page 22). In the absence of validated test method or guidance documents, this data requirement is waived in accordance to SANCO Guidance Document SANCO/10181/2013-rev 2.1 (13 May 2013).

This entry is taken from public literature and was not included in the study list of the application.

Report: CA 5.1.2/1
Takaku T. et al., 2011a
In vitro metabolism of trans-Permethrin and its major metabolites, PBalc and PBacid, in humans
2011/1297011
Guidelines: none
GLP: no
(certified by none)

Executive Summary

In the present study, to compare the metabolic profiles (route and rate) between rats and humans, the in vitro metabolism of trans-permethrin by hepatic microsomes from rats and humans was investigated. Trans-[Phenoxyphenyl-^{14}C]permethrin or [phenoxyphenyl-^{14}C] PBalc was incubated at 2.7-98 µM with or without 3 mM NADPH in the presence of male rat, female rat or human liver microsomes. The incubations were carries out for 60 min at 37 °C and stopped by addition of acetonitrile. Control experiments were performed without liver microsomes.
In addition, the P450 isoforms responsible for the 40-hydroxylation of 3-phenoxybenzyl alcohol (PBalc) and the UGT isoforms responsible for the glucuronidation of PBacid were identified. Furthermore, glucuronidation of 3-phenoxybenzoic acid (PBacid) in humans was examined.
In the following, only the results of the in-vitro metabolism of trans-permethrin by hepatic microsoms are described.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description:	Trans-[Phenoxyphenyl-^{14}C]permethrin and [phenoxyphenyl-^{14}C]PBalc; specific activity: 4.44 GBq/mmol
Lot/Batch #:	not applicable
Purity:	100.0% radiochemical purity
CAS#:	Trans-Permethrin: 61949-77-7 PBalc: 13826-35-2
Development code:	not applicable
Spiking levels:	Trans-[Phenoxyphenyl-^{14}C]permethrin: 2.7-98 µM and [phenoxyphenyl-^{14}C] PBalc: 2.7-98 µM
Stability of the test Compound:	not reported

2. Test Commodity:

Cell cultures: Liver microsomes from human (purchased from KAC Co., Ltd); liver microsomes from male and female Crj:CD(SD) rats (purchased from Charles River Japan Inc., Kanagawa, Japan)

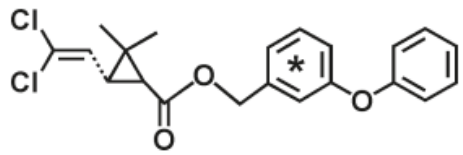
In vitro assay: In Vitro Metabolism of trans-Permethrin and PBalc with Human, Male Rat, and Female Rat Liver Microsomes
Trans-[Phenoxyphenyl-^{14}C]permethrin (2.7-98 µM) or [phenoxyphenyl-^{14}C] PBalc (2.7-98 µM) was incubated with or without 3 mM NADPH in the presence of human, male rat, and female rat liver microsomes (1 mg/mL) for 60 min at 37 °C. All incubations were carried out in 100 mM phosphate buffer (pH 7.4). Control experiments were performed without liver microsomes. After incubation, the reaction was terminated by addition of acetonitrile and the mixtures were stored on ice for 10 min and centrifuged at 10000 g for 5 min. The supernatant was analyzed by HPLC.

B. STUDY DESIGN AND METHODS

1. Test procedure

In the present study, to compare the metabolic profiles (route and rate) between rats and humans, the in vitro metabolism of trans-permethrin by hepatic microsomes from rats and humans was investigated. Trans-[Phenoxyphenyl-^{14}C]permethrin or [phenoxyphenyl-^{14}C] PBalc was incubated at 2.7-98 µM with or without 3 mM NADPH in the presence of male rat, female rat or human liver microsomes. The incubations were carries out for 60 min at 37 °C and stopped by addition of acetonitrile. Control experiments were performed without liver microsomes.
In addition, the P450 isoforms responsible for the 40-hydroxylation of 3-phenoxybenzyl alcohol (PBalc) and the UGT isoforms responsible for the glucuronidation of PBacid were identified. Furthermore, glucuronidation of 3-phenoxybenzoic acid (PBacid) in humans was examined. In the following, only the results of the in-vitro metabolism of trans-permethrin by hepatic microsoms are described.

Figure 5.1.2-1: Structural formula of trans-[phenoxyphenyl-^{14}C]permethrin



2. Description of analytical procedures

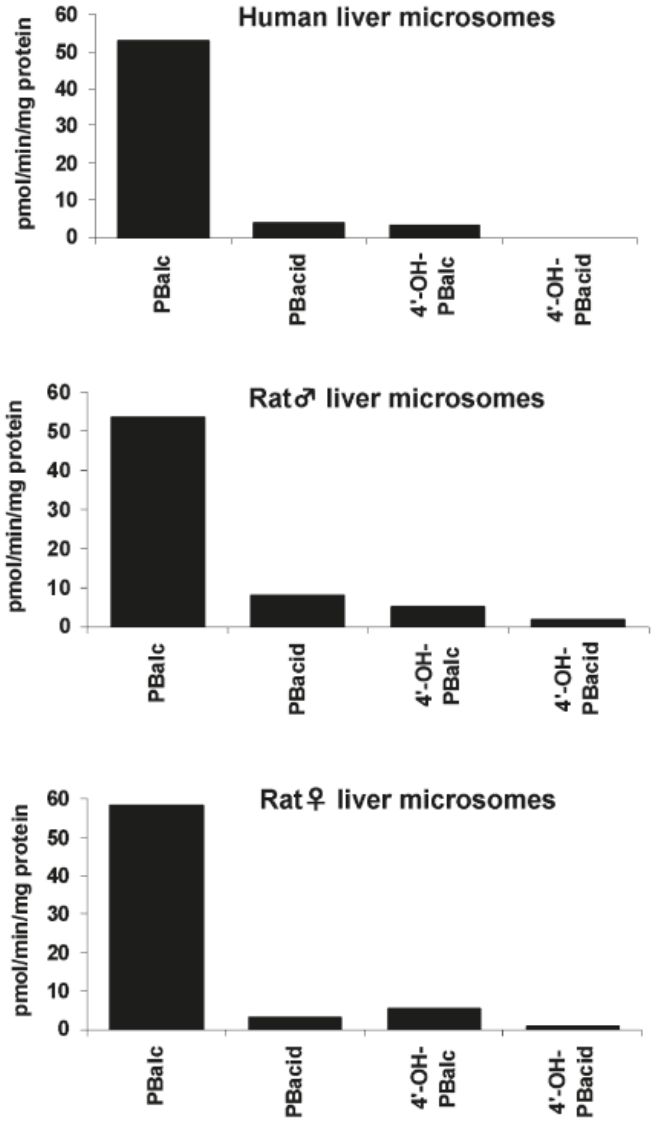
HPLC Analysis
HPLC was carried out on a system consisting of an L-6200 HPLC intelligent pump, an L-4000 UV detector and a Radiomatic 610TR RI detector fitted with an Atlantis dC18 column. The mobile phase consisted of acetonitrile and 0.1% (v/v) acetic acid in water. A flow rate of 1 mL/min was used. For the separation, a gradient program was used.

II. RESULTS AND DISCUSSION

1. Comparative in Vitro Metabolism of trans-[Phenoxyphenyl-^{14}C] permethrin

Trans-[Phenoxyphenyl-^{14}C]permethrin was incubated with human, male rat, and female rat liver microsomes each at concentrations of 2.7, 4.5, 17, 46, and 98 µM. In each incubation solution, PBalc, PBacid, and 4'-OH-PBalc were detected. PBalc (resulting from the hydrolysis of trans-permethrin) was the major metabolite in both humans and rats. The metabolites produced by human microsomes were nearly identical to those produced by rat liver microsomes, although 4'-OH-PBacid was not detected in a human liver microsomal incubation. The rates of metabolic formation were almost similar between humans and rats (see Figure 5.1.2-2). In this study, human and rat liver microsomes metabolized trans-permethrin mainly through hydrolysis, not oxidation, suggesting that the rapid hydrolysis is the major metabolic route of trans-permethrin in both humans and rats.

Figure 5.1.2-2: Rates of metabolite formation of trans-permethrin with human, male rat, and female rat microsomes.



III. CONCLUSION

The main metabolic pathway of trans-permethrin was the hydrolysis of the ester linkage to give PBalc in humans and rats. The metabolites produced by both rat and human microsomes (PBalc, PBacid, and 4'-OH-PBalc) were nearly identical except for 4'-OH-PBacid, which was not detected in a human liver microsomal incubation.

CA 5.2 Acute Toxicity

Studies evaluated in the draft monograph of alpha-cypermethrin by the rapporteur member state Belgium (1999): Alpha-cypermethrin (BAS 310 I) has been tested in various species and via different routes of administration. All studies are scientifically valid; however, partially the studies have been conducted before the release of study guidelines and are without GLP according to the usual practice in those days. These studies have been evaluated by European authorities and Belgium as Rapporteur Member State (European Commission Peer Review Program) and are, for the convenience of the reviewer, listed in Table 5.2-1**:**. Brief summaries of the respective studies were extracted from the monograph of alpha-cypermethrin and are provided under the respective chapters.

[1] This study is not BASF proprietary, but owned by Gharda, Chemical Ltd. Bombay, a further notifier for Annex I listing of alpha-cypermethrin in 1999.

Furthermore, based on human observations and indications in animal studies alpha-cypermethrin is considered to be irritating to the respiratory tract after single exposure (decision by ECB, 2001). Based on the data available at that time, the following EU agreed endpoints were given in the Review Report (SANCO/4335/2000 final; Doc ID 2004/1040515) from 2004:

Acute toxicity

Rat LD_{50} oral:	57 mg/kg bw (corn oil) T, R 25
Rat LD_{50} dermal:	> 2000 mg/kg bw
Rat LC_{50} inhalation:	> 0.593 mg/L (4-h, nose/mouth) (max. attainable concentration) R 37
Skin irritation:	Non-irritant
Eye irritation:	Non-irritant
Skin sensitization (M&K):	Not skin sensitizing

Submission of not yet peer-reviewed studies in this AIRIII-Dossier:
New oral, dermal and inhalation acute toxicity, skin and eye as well as sensitization studies according to current criteria have been performed with alpha-cypermethrin for global registration and for production site comparison.
In accordance with the data requirements of Commission Regulation SANCO/11802/2010 an in vitro NRU-Phototoxicity study in Balb/c 3T3 cells has been performed and is given in detail in chapter CA 5.2.7. All new studies are submitted within the AIR III process and are tabulated inTable 5.2-3.

in vitro NRU-Phototoxicity study	Balb/c 3T3 cells	99.4% / DMSO 1% in PBS	Not phototoxic	KCA 5.2.7/1 2013/1389105

The two batches tested from the different production sites showed similar results and were tested according to current guidelines in CMC or pure. Under these conditions alpha-cypermethrin has low acute toxicity by the oral and dermal route. The toxicity by the inhalation route is moderate with an LC_{50} of 1.33 mg/L and 2.5 mg/L. Alpha-Cypermethrin does not induce skin or eye irritation and is neither sensitizing nor shows phototoxic potential in Balb/c 3T3 cells.

The solutions of alpha-cypermethrin in corn oil are substantially more toxic than those in water, in DMSO or in suspension. Therefore, the new studies for acute oral toxicity performed with aqueous suspensions do not affect the LD_{50} relevant for classification. The new studies were only taken into consideration for the classification proposal when they indicated higher toxicity than seen in the original data set. This is only the case for acute inhalation toxicity.

Considering all available studies alpha-cypermethrin is acutely toxic by the oral route and harmful via inhalation. Based on human and animal data alpha-cypermethrin is regarded as irritating to the respiratory tract after single exposure. Very low toxicity is induced by the percutaneous route. Alpha-Cypermethrin is no skin or eye irritant, not a skin sensitizer and not phototoxic.

The proposed endpoints based on all available studies are shown below in Table 5.2-4

Table 5.2-4: Proposed acute toxicity endpoints of alpha-cypermethrin*

Study type/species	Results	Classification
		Reg. EC 1272/2008 (CLP)
Acute oral toxicity, rat	LD_{50} = 57 mg/kg bw	Acute tox 3 (H301)
Acute dermal toxicity, rat	LD_{50} > 2000 mg/kg bw	-
Acute inhalation toxicity, rat	**LC_{50} (f) = 1.21 mg/L**	Acute tox 4 (H332) STOT SE 3 (H335)
Dermal irritation, rabbit	Slightly Irritating	-
Eye irritation, rabbit	Not irritating	-
Maximisation test, guinea pig	Not sensitising (M & K maximisation test)	-
In vitro NRU Phototoxicity Test, Balb/c 3T3 cells	**Not phototoxic**	-

* new endpoints or values differing from the current agreed EU endpoints are marked in bold

Under consideration of all available data the harmonized classification of alpha-cypermethrin will differ under Reg. EC 1272/2008 (CLP) with regard to the additional classification as Acute tox 4 (H332). The List of endpoints will be adapted accordingly as shown below:

Acute toxicity (SANCO/11802 data point 5.2)

Rat LD_{50} oral	LD_{50} = 57 mg/kg bw Acute tox 3 (H301)
Rat LD_{50} dermal	LD_{50} > 2000 mg/kg bw No classification required
Rat LC_{50} inhalation	LC_{50} (f) = 1.21 mg/L **Acute tox 4 (H332),** STOT SE 3 (H335)
Skin irritation	Mildly irritating No classification required
Eye irritation	Not irritating No classification required
Skin sensitization (test method used and result)	Not sensitising (M & K maximisation test) No classification required

Acute toxicity (SANCO/11802 data point 5.2)

Phototoxicity	Not phototoxic No classification required

For convenience of the reviewer brief summaries of the respective studies as extracted from the monograph of alpha-cypermethrin are provided below together with the summaries of recently conducted studies.

CA 5.2.1 Oral

[redacted] 1993 (AL-410-003)

Guidelines: In compliance with the test method B.1 of directive 92/69/EEC
GLP: Yes
Acceptance: The study was considered acceptable in the EU registration process 1999.

5 Crl:CD:BR rats/sex received by gavage a single dose of alpha-cypermethrin (95.6%, cis1:cis2 ratio: 3:97) in corn oil at dose levels of 33, 46, 64, 90 and 126 mg/kg bw.
Mortalities occurred between four hours after dosing and day 3. There were deaths among rats dosed at 46 mg/kg bw (3♂, 1♀), at 64 mg/kg bw (3♂) at 90 mg/kg bw (3♂, 5♀) and at 126 mg/kg bw (5♂, 5♀). Clinical signs comprised hunched posture, piloerection, diarrhoea, an unkempt appearance and yellow staining of the anogenital fur at all dose levels. In animals that died, the following clinical signs were observed in addition: splayed gait, thrashing and bloody discharge from the mouth and nose, twitching, tremor, fasciculations, convulsions, vasodilatation, salivation and in isolated cases lacrimation, chromodacryorrhoea, lethargy, abasia vocalisation (distressed noises), hypothermia, cyanosis, bradypnoea and prostration. Surviving animals gained body weight as expected over the 14 day observation period. At pathology, pallor or a darkened appearance of the liver, kidneys and spleen, lung congestion and abnormal content of the stomach and small intestines was observed.

Conclusion
Under the conditions of this study, the LD_{50} for male and female animals was considered to be 57 and 71 mg/kg bw, respectively.

[redacted] 1993

Guidelines: In compliance with the test method B.1 of directive 92/69/EEC
GLP: Yes
Acceptance: The study was considered acceptable in the EU registration process 1999.

5 Sprague Dawley rats/sex received alpha- Cypermethrin (95% - 99.5%) in corn oil by gavage at dose levels of 180, 280, 440 and 700 mg/kg bw.
Mortalities occurred within 2 days after dosing. There were deaths among rats dosed at 280 mg/kg bw (2♂, 2♀), at 440 mg/kg bw (4♂, 2♀) and at 700 mg/kg bw (5♂, 4♀). Clinical signs comprised nasal secretion, lacrimation, salivation, polyuria, ataxia, drowsiness, tremors and convulsions. Surviving animals were free of symptoms on 1 to 4 days after treatment. Body weight development was unaffected. At pathology, hermorrhage and congestion in lung and liver of the animals that died during the study was observed.

Conclusion
Under the conditions of this study, the LD_{50} for male and female animals was considered to be 310 and 430 mg/kg bw, respectively.

[redacted] 1982a (AL-411-004)

Guidelines: Not fully in compliance with the test method B.1 of directive 92/69/EEC
Deviations: Variability in test volume was not minimized by adjusting the concentration to ensure a constant volume at all dose levels
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

6 Wistar rats/sex received by intubation a single dose of alpha-cypermethrin (96.6%, cis1:cis2 ratio: 3.3:96.7) as 40% solution in DMSO at dose levels of 394, 626, 995, 1582, 2515 and 4000 mg/kg bw (group 1) and as 50% aqueous suspension in carboxy-methylcellulose at dose levels of 492, 782, 1244, 1978, 3144 and 5000 mg/kg bw (group 2). In group 1 all deaths occurred within 2 days of dosing at 995 mg/kg bw (1♂), 1582 mg/kg bw (1♂, 1♀), 2516 mg/kg bw (2♂) and at 4000 mg/kg bw (4♂). In group 2, one female animal of the 5000 mg/kg bw dose group died. Clinical signs in group 1 were observed over all dose levels until study day 2 and comprised salivation, lethargy, diarrhea, piloerection, clonic convulsions, blood around nose (some animals), tip-toe hind leg walk and lacrimation. In group 2, clonic convulsions, salivation, lethargy, aggressive, abasia, piloerection, diarrhea, hypersensitivity to sensory stimuli, blood around the nose and chromodacryorrhoea were observed until day 4 over all dose levels. In group 1, all surviving animals recovered from an initial weight loss until the end of the 14 day observation period. In group 2, body weight decrease was observed at the highest dose but reversed by the end of the 14-day observation period except for two males. Description of necropsy findings are missing.

Conclusion
Under the conditions of this study, the LD_{50} for male and female animals was considered to be 4000 and >4000 mg/kg bw, respectively, for the solution in DMSO (group 1) and >5000 mg/kg bw for the aqueous suspension (group 2).

[redacted] 1982b (AL-411-005)

Guidelines: Not fully in compliance with the test method B.1 of directive 92/69/EEC
Deviations: Variability in test volume was not minimized by adjusting the concentration to ensure a constant volume at all dose levels
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

6 Wistar rats/sex received by intubation a single dose of alpha-cypermethrin (99.4%, b,n° OCD/7) as 10% solution in corn oil at dose levels of 10, 20, 40, 80, 160 and 320 mg/kg bw (group 1) and as 20% solution in corn oil at dose levels of 99, 158, 251, 400, 635 and 800 mg/kg bw (group 2). In group 1, all deaths occurred within 2 days of dosing at 80 mg/kg bw (4♂, 4♀) and at 160 mg/kg bw (6♂, 6♀). In group 2, all deaths occurred within 3 days of dosing at 158 mg/kg bw (1♀), 251 mg/kg bw (2♂, 3♀), 400 mg/kg bw (2♂, 5♀), 635 mg/kg bw (6♂, 4♀) and 800 mg/kg bw (6♂, 3♀). Clinical signs in group 1 comprised piloerection, abasia, salivation, splayed hind leg gait, lethargy, diarrhea, clonic convulsion, tremor, blood around mouth and abnormal respiratory and were observed over all groups. In group 2, clonic convulsion, abasia, piloerection, diarrhea, lethargy, salivation, tremors, ataxia, splayed hind leg gait, chromodacryorrhoea, blood around nose was observed over all dose levels. All surviving animals recovered from an initial weight loss until the end of the 14 day observation period. Description of necropsy findings are missing.

Conclusion
Under the conditions of this study, the LD_{50} for male and female animals was considered to range from 40 to 80 mg/kg bw for the 10% solution (group 1) and from 282 to 487 mg/kg bw for 20% suspension (368 mg/kg bw, group 2).

Report:	CA 5.2.1/1 [redacted] 2005a BAS 310 I (Alpha-Cypermethrin) - Acute oral toxicity study in rats 2005/1011568
Guidelines:	OECD 423, EEC 2004/73 B.1 tris, EPA 870.1100
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

Single doses of 2000, 300 and 50 mg/kg bw of BAS 310 I (batch: COD-000166; purity: 99.3%) preparations in 0.5% CMC-solution in doubly distilled water were given to 4 administration groups of three fasted female animals, each (2000 mg/kg in 6 females, 300 and 50 mg/kg in 3 females each) by gavage in a sequential manner. Animals were observed for 14 days. No mortality occurred in the administration groups. Accordingly, the oral LD_{50} was found to be greater than 2000 mg/kg bw:

Rat, oral: LD_{50} > 2000 mg/kg bw

No clinical signs and findings were observed. The mean body weights of the administration groups increased throughout the study period. No macroscopic pathologic abnormalities were noted in the animals examined at the end of the observation period.
Under the conditions of this study the median lethal dose of BAS 310 I after oral administration was found to be greater than 2000 mg/kg bw in rats. DocID (2005/1011568)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	BAS 310 I (alpha-cypermethrin)
Description:	Solid; powder/white
Lot/Batch #:	COD-000166
Purity/content:	99.3%
Stability of test compound:	The stability of the test substance in the vehicle was determined indirectly by the concentration control analysis.
2. Vehicle:	0.5% CMC-solution (cleaned sodium carboxymethylcellulose) in doubly distilled water

3. Test animals:

Species:	Rat
Strain:	Wistar / HanRcc:WIST(SPF)
Sex:	female
Age:	approximately 8 -12 weeks
Weight at dosing (mean):	172 - 188 g
Source:	RCC Ltd Laboratory Animal Services, Wölferstrasse 4, CH-4414 Füllinsdorf, Switzerland
Acclimation period:	At least 5 days
Diet:	Kliba-Labordiät (Maus / Ratte Haltung "GLP"), Provimi Kliba SA, Kaiseraugst, Basel, Switzerland, ad libitum
Water:	Tap water, ad libitum
Housing:	Single housing in stainless steel wire mesh cages, type DK-III (Becker & Co., Castrop-Rauxel, FRG)

Environmental conditions:

Temperature:	20 - 24 °C
Humidity:	30 - 70 %
Air changes:	Central air-conditioning
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 6 am to 6 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 15-Feb-2005 - 12-Apr-2005

2. Animal assignment and treatment:

Single doses of 2000, 300 and 50 mg/kg bw of test material preparations in 0.5% CMC-solution in doubly distilled water were given to 4 administration groups of three fasted animals each (2000 mg/kg in 6 females, 300 and 50 mg/kg in 3 females) by gavage in a sequential manner. Clinical signs and symptoms were recorded several times on the day of administration and afterwards at least once each workday for the individual animals up to 14 days post-administration. A check for any dead or moribund animal was made twice each workday and once on Saturdays, Sundays and public holiday. Individual body weights were determined shortly before administration, weekly thereafter and at the end of the study. The animals were sacrificed by CO_2-inhalation and subjected to necropsy including gross pathological examination on the last day of the observation period or as soon as possible after death in case of animals that died before.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality occurred in the administration groups.

B. CLINICAL OBSERVATIONS

No clinical signs and findings were observed.

C. BODY WEIGHT

The mean body weights of the administration groups increased throughout the study period.

D. NECROPSY

No abnormalities were observed at gross necropsy.

III. CONCLUSION

Under the conditions of this study, the oral LD_{50} in rats for BAS 310 I was determined to be greater than 2000 mg/kg bw.

Report:	CA 5.2.1/2 [redacted] 2005b BAS 310 I (Alpha-Cypermethrin) - Acute oral toxicity study in rats 2005/1011604

III. CONCLUSION

Under the conditions of this study, the oral LD_{50} in rats for BAS 310 I was determined to be greater than 2000 mg/kg bw.

CA 5.2.2 Dermal

[redacted] **1993 (AL-410-003)**

Guidelines: Not fully in compliance with the test method B.3 of directive 92/69/EEC
Deviations: Occlusive dressing was used
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

5 Crl:CD:BR rats/sex were exposed to undiluted alpha-cypermethrin (95.6%, cis1:cis2 ratio: 3:97) at a dose level of 2000 mg/kg bw, by dermal occlusive application for 24 h.
Mortality was not observed. Clinical signs comprised salivation, hypersensitivity to stimuli, staining of anogenital fur and hyperactivity from day 2 but until day 4. Sites of application of the test material were discoloured (white) after removal of the dressings on day 2. This effect disappeared on day 5. At pathology, limited to slight vascular congestion of the sites of application of the test material was observed.

Conclusion
Under the conditions of this study, the LD50 for male and female animals was >2000 mg/kg bw.

Pore, 1992

Guidelines: In compliance with the test method B.3 of directive 92/69/EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

5 albino Sprague-Dawley rats/sex were exposed to solid alpha-cypermethrin (96%) at a dose level of 2000 mg/kg bw, by dermal semi-occlusive application for 24 h.
Mortality, clinical signs and local effects were not observed.

Conclusion
Under the conditions of this study, the LD_{50} for male and female animals was >2000 mg/kg bw.

BAS 310 I (Alpha-Cypermethrin) - Acute dermal toxicity study in rats
2005/1011569
Guidelines: OECD 402, EEC 92/69 B 3, EPA 870.1200
GLP: yes
(certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute dermal toxicity study groups of 5 male and 5 female Wistar rats were exposed to 2000 mg/kg bw of a test material (batch COD-000166; purity: 99.3%) preparation in 0.5% CMC solution in doubly distilled water. The preparation was applied to the clipped skin under semi-occlusive conditions for 24 hours. The animals were observed for 14 days after administration. No mortality occurred in the male dose group. One animal of the female dose group was found dead on study day 13. However, this was considered to be due to an abszess of the lower jaw and not test substance related. Accordingly, the LD_{50} was determined to be greater than 2000 mg/kg bw:

Rat, dermal: LD_{50} > 2000 mg/kg bw

No systemic clinical observations or skin effects were noted in the animals. The mean body weights of the animals increased throughout the study period. During necropsy the animal that died showed a green to yellow pasty abszess (1 mL) of the right lower jaw. No further macroscopic pathologic abnormalities were noted in the surviving animals at the end of the study.

B. STUDY DESIGN AND METHODS

1. Dates of work: 01-Mar-2005 - 12-Apr-2005

2. Animal assignment and treatment:

Five male and five female rats were given a single application of test material preparation in 0.5% CMC solution in doubly distilled water to the clipped epidermis on the dorsal and dorsolateral parts of the trunk (about 40 cm^2, corresponding to at least 10% of the body surface) for 24 hours. The fur was clipped one day before application of the test substance.
A bandage consisting of four layers absorbent gauze (Ph. Eur. Lohmann GmbH & co. KG) with the calculated amount of the test substance was applied to the test site. The application site was covered with a semi-occlusive dressing (Fixomull Stretch (adhesive fleece), Beiersdorf AG). After the exposure period, the dressing and the bandage were removed and residual test substance was rinsed with warm water.
Rats were observed for signs and symptoms several times on the day of application and afterwards at least once each workday for a total of 2 weeks. Individual body weights were determined shortly before application, weekly thereafter and at the end of the study. Necropsy with gross-pathology examination on the last day of the observation period was done after killing the animals with CO_2.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality occurred in the male dose group.
One animal of the female dose group was found dead on study day 13. However, this was considered to be due to an abszess of the lower jaw and not test substance related.

B. CLINICAL OBSERVATIONS

No systemic clinical observations or skin effects were noted in the animals.

C. BODY WEIGHT

The mean body weights of the animals increased throughout the study period.

D. NECROPSY

[redacted] **993 (AL-413-001)**

Guidelines: In compliance with the test method B.2 of directive 92/69/EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

5 Sprague-Dawley rats/sex were exposed for 4 hours by inhalation exposure to an atmosphere contacting 0.98 and 1.59 mg/L of alpha-cypermethrin (95.6%) produced by a dust generator (MMAD: 6.1 – 9 mm, 49.3 and 34.8% respirable).
One female animal of the 0.98 mg/L dose group died. Clinical signs comprised exaggerated or irregular respiratory movements during exposure and exaggerated respiratory movements, staggering, fascicular tremors, writhing, ataxia, hunched posture, poorly groomed appearance and yellow staining around the urogenital region post-exposure until day 6 of the observation period. Body weight gain was reduced for up to 2 days following exposure. At pathology, lungs of the rat that died were moderately congested and stomach distended with gas. At the high dose, surviving rats showed dark subpleural foci on the lung in two animals. No abnormalities were observed at 0.98 mg/L.

Conclusion
Under the conditions of this study, the LC_{50} for male and female animals was >1.59 mg/L.

[redacted] **1994**

Guidelines: In compliance with the test method B.2 of directive 92/69/EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

5 Sprague-Dawley rats/sex were exposed for 4 hours by nose and mouth route to an atmosphere containing 0.593 mg/L (max. attainable concentration) of alpha-cypermethrin (95 - 99.5%) produced by a dust generator (MMAD: 5.1 mm, respirable range of 0-7 mm).
No mortality was observed. Clinical signs comprised nasal secretion, lacrimation, salivation, polyurea and wet fur at the termination of the exposure period. Nasal secretion was observed further on in females until study day 8 and in males until day 12. No effects on body weight development were observed. At pathology, congestion of the lung was observed in one male and one female animal each.

Conclusion
Under the conditions of this study, the LC_{50} for male and female animals was >0.593 mg/L.

Report:	CA 5.2.3/1 [redacted] 2005e BAS 310 I (Alpha-Cypermethrin) - Acute inhalation toxicity study in Wistar rats - 4-hour dust exposure 2005/1013246
Guidelines:	OECD 403, EEC 92/69, EPA 870.1300, EEC 67/548 Part B.2 L383A, EPA 712-C-98-193
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute inhalation toxicity study, groups of 5 male and 5 female Wistar rats were exposed to alpha-cypermethrin as dust (Batch COD-000165; Purity: 98.8%) at concentrations of 1.07 and 2.47 mg/L for 4 hours. The animals were observed for 14 days after exposure.
No mortality occurred at 1.07 mg/L. At 2.47 mg/L, one of five male and four of five female animals died. Accordingly, the acute inhalation LC_{50} for alpha-cypermethrin after dust inhalation exposure was determined to be:

LC50 (females) : 2.29mg/L
LC50 (males) : 2.79 mg/L
LC_{50} (male and female rats): 2.5 mg/L

Clinical signs of toxicity in animals exposed to 1.07 mg/L comprised visually accelerated respiration, eyelid closure, apathy, squatting posture, tremor, ataxia, startle reflex and smeared fur. Clinical signs of toxicity in animals exposed to 2.47 mg/L comprised some additional unspecific symptoms like gasping, discharged nose and salivation, indicative for respiratory distress, local irritant action and systemic toxicity. Findings were observed from hour 0 of exposure until study day 7. In the 1.07 mg/L dose group the mean body weight of the male animals did not increase adequately during the first post exposure observation week, but increased during the second week. The mean body weight of the female animals did not increase adequately throughout the whole study period. This effect is observed at times in the rat strain used, because in the required age range the female animals have already reached the phase of slow growth. No gross pathological abnormalities were noted in the animals necropsied at termination of the post exposure observation period. Regarding the 2.47 mg/L dose group, the mean body weight of the male animals decreased during the first post exposure observation week, but increased during the second week. The body weight of the only surviving female animal increased slightly throughout the whole study period. During necropsy, dark red discoloration of all lung lobes were noted in two female animals that died one day after exposure. Additionally, contaminated and wet fur around the snout were noted in all three female animals that died one day after exposure. No gross pathological abnormalities were noted in the one male and the one female animal that died 1 hour after exposure. No gross pathological abnormalities were noted in all animals that were necropsied at termination of the study. Cascade impactor measurements resulted in particle size distributions with a mass median aerodynamic diameters (MMAD) of 2.7 - 2.8 µm and a geometric standard deviation (GSD) of 2.7 – 2.8.

(DocID 2005/1013246)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	BAS 310 I
Description:	Solid; powder/white
Lot/Batch #:	COD-000165
Purity/content:	98.8%
Stability of test compound:	Stable (Expiry date: 01-Nov-2006)
2. Vehicle:	Test substance was applied unchanged.
3. Test animals:	
Species:	Rat
Strain:	Wistar / RccHan™:WIST
Sex:	male and female
Age:	Males: approx. 8 - 10 weeks; females: approx. 8 - 12 weeks
Weight at dosing (mean):	Males: 264.0 g; females: 201.6 g
Source:	RCC Ltd Laboratory Animal Services; Wölfersraße 4, CH-4414 Füllinsdorf
Acclimation period:	at least 1 week
Diet:	KLIBA mouse / rat laboratory diet 10 mm pellets "GLP", Provimi Kliba SA, Kaiseraugst, Basel Switzerland, ad libitum
Water:	Drinking water, ad libitum
Housing:	Singly in cages type DK III (Becker, Germany) without bedding.
Environmental conditions:	
Temperature:	20 - 24 °C
Humidity:	30 - 70%
Air changes:	No data. The animals were kept in fully air-conditioned rooms.
Photo period:	Alternating 12-hour light and dark cycles

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 27-Apr-2005 - 14-Jul-2015

2. Animal assignment and treatment:

For determination of the acute inhalation toxicity (head-nose inhalation, 4-hour-exposure) groups of five male and five female rats were exposed to 1.07 and 2.47 mg/L of the test substance. The test substance was desagglomerated in a mixer under addition of 2 % (w/w) of Aerosil® R972 before introduction into the dust generator, in order to improve dust formation. After exposure, animals were observed for 14 days. Individual body weights were recorded on arrival, shortly before exposure (day 0) and on days 7 and 14. Additionally, body weight was measured in animals that died from study day 1 onward. A check for overt clinical signs of toxicity or mortality as well as a check for the presence of feed and drinking water was made twice a day on workdays and once daily on weekends and public holidays. Detailed clinical observations were recorded for each animal separately several times during exposure and at least once on each workday of the observation period. Additionally, on one Saturday details clinical observation was carried out in both test groups. At the end of the observation period the surviving animals that were sacrificed with CO_2 were subjected to gross-pathological examination like all other animals which had died before.

3. Statistics/calculations:

The LC_{50} was calculated by Probit analysis by means of a computer program. For results of the type ”LC_{50} greater than”, ”LC_{50} approx.”, or ”LC_{50} smaller than”, the binomial test was used for statistical evaluation. The calculation of the particle size distribution was carried out in the inhalation laboratory on the basis of mathematical methods for evaluating particle measurements.

4. Generation of the test atmosphere and exposure:

The test substance was desagglomerated in a mixer under addition of 2 % (w/w) of Aerosil® R972 before introduction into the dust generator, in order to improve dust formation. For each test group the dust was produced inside the dust pre-chamber with a dosing-wheel dust generator (Gericke/BASF) and compressed air and passed into the inhalation system. The concentrations of the dust in the atmosphere were adjusted by varying the apertural width and rotation of the dosing wheel. The exposure systems were located inside an exhaust cabin in an air-conditioned laboratory. A supply air flows (compressed air) of 1.5 m³/h were used for the exposures. The exhaust air flows were set to 1.35 m³/h. An air change of about 27 times per hour can be calculated by dividing the supply air flows by the volume of the inhalation systems. The lower amounts of exhaust air, which were adjusted by means of a separate exhaust air systems, achieved positive pressure inside the exposure systems. This ensured that the mixtures of test substance and air were not diluted with laboratory air in the breathing zones of the animals. The animals were exposed to the inhalation atmospheres for 4 hours plus equilibration time of the inhalation systems (t_{99} about 10 min).

5. Analytical investigation:
The flows of supply and exhaust air were adjusted and continuously measured with flowmeters (Rota). They were recorded four times in about 1-hour intervals. The temperature in the inhalation systems were measured continuously with a digital thermometer and recorded four times in about 1-hour intervals. The humidities in the inhalation systems were measured with a dielectric probe four times in about 1-hour intervals. No surveillance of the oxygen content in the inhalation systems was performed. The air change was judged to be sufficient to prevent oxygen depletion by the breathing of the animals, and the concentrations of the test substance used could not have a substantial influence on oxygen partial pressure. The nominal concentration was calculated from the amounts of substance dosed and the supply air flows.
Gravimetric determination of the inhalation atmosphere concentration was performed with a balance Mettler AT 250. Preweighed filters were placed into the filtration equipment. By means of the vacuum pump metered volumes of the dust aerosol were drawn through the filter. For each sample the dust aerosol concentration in mg/L was calculated from the difference between the preweight of the filter and the weight of the filter after sampling, with reference to the sample volume of the inhalation atmospheres. Mean and standard deviation were calculated for the concentration from the results of the individual measurements. The mean concentration were corrected for the amount of additive used

6. Particle Size Analysis:
Before sampling, the impactor was assembled with preweighed glass-fiber collecting discs, and a backup particle filter. The impactor was connected to the vacuum pump and one sample per exposure was taken from the breathing zone of the animals starting not earlier than 30 minutes after the beginning of the exposure. The sample volumes were 6 and 15 L. After sampling the impactor was taken apart. The collecting discs and the backup particle filter were re-weighed. The amounts of material adsorbed to the walls of the impactor and in the sampling probe (wall losses) were also determined quantitatively. The results from the particle size analysis were not corrected for the additive.

II. RESULTS AND DISCUSSION

A. MORTALITY

No lethality occurred at the tested concentration of 1.07 mg/L during the study period of 14 days. At 2.47 mg/L one male and 4 female animals died.

Table 5.2.3-1: Lethality in rats exposed for 4 hours to BAS 310 I as dust

Test group (mg/L)	Cumulated lethality		Time interval of lethality
	Males	Females	
1.07	0/5	0/5	-
2.47	1/5	4/5	d0 – d1

B. CLINICAL OBSERVATIONS

The nature and duration of the observations are indicated in Table 5.2.3-2. All animals recovered within the 14-day observation period.

Table 5.2.3-2: Nature and duration of clinical signs observed in rats exposed for 4 hours to BAS 310 I as dust

	Males		Females	
Test group (mg/L)	**1.07**	**2.47**	**1.07**	**2.47**

hn: hour n of exposure; d0: post-exposure on the day of exposure; dn: day n after exposure

C. BODY WEIGHT

Regarding the 1.07 mg/L dose group, the mean body weight of the male animals did not increase adequately during the first post exposure observation week, but increased during the second week. The mean body weight of the female animals did not increase adequately throughout the whole study period. This effect is observed at times in the rat strain used, because in the required age range the female animals have already reached the phase of slow growth.

In the 2.47 mg/L dose group, the mean body weight of the male animals decreased during the first post exposure observation week, but increased during the second week. The body weight of the only surviving female animal increased slightly throughout the whole study period.

D. NECROPSY

Regarding the 1.07 mg/L dose group, no gross pathological abnormalities were detected the animals that were necropsied at termination of the study.
In the 2.47 mg/L dose group, dark red discoloration of all lung lobes were noted in two female animals that died one day after exposure. Additionally, contaminated and wet fur around the snout were noted in all three female animals that died one day after exposure. No gross pathological abnormalities were noted in the one male and the one female animal that died 1 hour after exposure.
No gross pathological abnormalities were noted in all animals that were necropsied at termination of the study.

E. ANALYTICAL MEASUREMENTS

The exposure conditions are summarized in Table 5.2.3-3.

Table 5.2.3-3: Exposure conditions

Test group (mg/L)	Supply air (m^3/h)	Exhaust air (m^3/h)	Temperature (°C)	Relative humidity (%)	Substance f (g/h)[4]
1.07	1.5	1.35	21.5±0.3	55.5±0.6	20.9
2.47	1.5	1.35	21.4±0.1	51.7±0.6	53.8

[4] corrected for 2 % (w/w) Aerosil.

Test atmosphere concentrations are presented in Table 5.2.3-4.

Table 5.2.3-4: Atmosphere concentrations

Mean achieved (mg/L)	Standard deviation	Nominal (mg/L)
1.07	0.21	13.9
2.47	0.49	35.9

The measurements of particle-size distribution revealed mass median aerodynamic diameters (MMAD) of 2.7 – 2.8µm with a geometric standard deviation of 2.7 - 2.8 respectively (see Table 5.2.3-5).

Table 5.2.3-5: Particle size distribution

Mean achieved (analytical) atmosphere concentration (mg/L)	Mean mass median aerodynamic diameter (µm)	Inhalable fraction (% <3 µm)	Standard deviation
1.07	2.7	54.6	2.7
2.47	2.8	53.1	2.8

III. CONCLUSION

Under the conditions of this study the 4 hour inhalation LC_{50} of alpha-cypermethrin for male and female rats was estimated to be 2.5 mg/L.

Report:	CA 5.2.3/2 [redacted] 2005a BAS 310 I (Alpha-Cypermethrin) - Acute inhalation study in Wistar rats - 4-hour dust exposure 2005/1015687
Guidelines:	OECD 403, EPA 870.1300, EEC 92/69 B 2, EEC 67/548, EPA 712-C-98-193
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute inhalation toxicity study, groups of 5 male and 5 female Wistar rats were exposed to alpha-cypermethrin as dust (Batch COD-000166; Purity: 99.3%) at concentrations of 0.42 and 1.16 mg/L for 4 hours. The animals were observed for 14 days after exposure.
No mortality occurred at 0.42 mg/L. Two of five females but no males died at 1.16 mg/L. Accordingly, the acute inhalation LC_{50} for alpha-cypermethrin after dust inhalation exposure was determined to be:

LC_{50} (female rats): 1.21 mg/L
LC_{50} (male rats): >1.16 mg/L
LC_{50} (male and female rats): 1.33 mg/L

Clinical signs of toxicity in animals exposed to 0.42 mg/L comprised visually accelerated respiration, squatting posture, piloerection and smeared fur. Findings were observed from hour 0 of exposure until including study day 2. Clinical signs of toxicity in animals exposed to 1.16 mg/L comprised visually accelerated respiration, squatting posture, tremor, abdominal position, staggering, high-stepping gait, startle reflex, piloerection and smeared and contaminated fur. Moreover, reddish discoloration in the anogenital region and around the snout was observed. Findings were observed from hour 0 of exposure until including study day 6. In the 0.42 mg/L dose group, the mean body weight of the male animals increased throughout the study period. The mean body weights of the female animals decreased slightly during the first post exposure observation week and increased slightly during the second week. This effect is observed at times in the rat strain used, because in the required age range the female animals have already reached the phase of slow growth. Regarding the 1.16 mg/L dose group, the mean body weight of the surviving animals increased throughout the study period. No gross pathological abnormalities were noted at pathology. Cascade impactor measurements resulted in particle size distributions with a mass median aerodynamic diameters (MMAD) of 2.6 - 2.8 µm and a geometric standard deviation (GSD) of 2.8 – 3.7.

The impactor was connected to the vacuum pump and one sample per exposure was taken from the breathing zone of the animals starting not earlier than 30 minutes after the beginning of the exposure. The sample volume were 30 and 15 L. After sampling the impactor was taken apart. The collecting discs and the backup particlevfilter were re-weighed. The amounts of material adsorbed to the walls of the impactor and in the sampling probe (wall losses) were also determined quantitatively. The results from the particle size analysis were not corrected for the additive.

II. RESULTS AND DISCUSSION

A. MORTALITY

No lethality occurred at the tested concentration of 0.42 mg/L during the study period of 14 days. At 1.16 mg/L 2 female animals died.

Table 5.2.3-6: Lethality in rats exposed for 4 hours to BAS 310 I as dust

Test group (mg/L)	Cumulated lethality		Time interval of lethality
	Males	Females	
0.42	0/5	0/5	-
1.16	0/5	2/5	d0 – d1

B. CLINICAL OBSERVATIONS

The nature and duration of the observations are indicated in Table 5.2.3-7. All animals recovered within the 14-day observation period.

Table 5.2.3-7: Nature and duration of clinical signs observed in rats exposed for 4 hours to BAS 310 I as dust

hn: hour n of exposure; d0: post-exposure on the day of exposure; dn: day n after exposure

C. BODY WEIGHT

Regarding the 0.42 mg/L dose group, the mean body weight of the male animals increased throughout the study period. The mean body weights of the female animals decreased slightly during the first post exposure observation week and increased only slightly during the second week. This effect is observed at times in the rat strain used, because in the required age range the female animals have already reached the phase of slow growth.
In the 1.16 mg/L dose group, the mean body weight of the surviving male and female animals increased throughout the study period.

D. NECROPSY

No gross pathological abnormalities were noted in all animals.

E. ANALYTICAL MEASUREMENTS

The exposure conditions are summarized in Table 5.2.3-8.

Table 5.2.3-8: Exposure conditions

Test group (mg/L)	Supply air (m^3/h)	Exhaust air (m^3/h)	Temperature (°C)	Relative humidity (%)	Substance flow (g/h)[4]
0.42	1.5	1.35	21.6±0.5	45.5±2.6	7.4
1.16	1.5	1.35	21.3±0.8	48.2±3.4	11.6

[4] corrected for 1 % (w/w) Aerosil.

Test atmosphere concentrations are presented in Table 5.2.3-9.

Table 5.2.3-9: Atmosphere concentrations

Mean achieved (mg/L)	Standard deviation	Nominal (mg/L)
0.42	0.03	4.9
1.16	0.24	7.7

The measurements of particle-size distribution revealed mass median aerodynamic diameters (MMAD) of 2.6 – 2.8µm with a geometric standard deviation of 2.8 -3.7 respectively (see Table 5.2.3-10).

Table 5.2.3-10: Particle size distribution

Mean achieved (analytical) atmosphere concentration (mg/L)	Mean mass median aerodynamic diameter (µm)	Inhalable fraction (% <3 µm)	Standard deviation
0.42	2.6	54.3	3.7
1.16 (sample 1)	2.8	52.8	2.9
1.16 (sample 2)	2.6	55.1	2.8

III. CONCLUSION

Under the conditions of this study the 4 hour inhalation LC_{50} of alpha-cypermethrin for male and female rats was estimated to be 1.33 mg/L.

CA 5.2.4 Skin irritation

[redacted] 1993 (AL-410-003)

Guidelines: In compliance with the test method B.4 of directive 92/69/EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

6 New Zealand white rabbits were exposed to 0.5 g alpha-cypermethrin (95.6%, cis1:cis2 ratio: 3:97) applied to the intact skin and covered with a semi-occlusive dressing during 4 h.
An overall mean erythema and edema score of 0.222 and 0, respectively, were determined over the 24, 48 and 72 h reading time points.

Conclusion
Under the conditions of this study, alpha-cypermethrin was considered not to be skin-irritating.

[redacted] 1994a

Guidelines: Not fully in compliance with the test method B.4 of directive 92/69/EEC
Deviations: Substance was applied on abraded skin
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

3 New Zealand white rabbits were exposed to 0.5 g alpha-cypermethrin (95% - 99.5%) applied to the shorn skin and covered with a semi-occlusive dressing during 4 h.
For both, erythema and edema, scores of 0/0/0 were determined for the three animals over the 24, 48 and 72 h reading time points.

Conclusion
Under the conditions of this study, alpha-cypermethrin was considered not to be skin-irritating.

Report:	CA 5.2.4/1 [redacted] 2005a BAS 310 I (Alpha-Cypermethrin) - Acute dermal irritation/corrosion in rabbits 2005/1011570
Guidelines:	OECD 404, EEC 2004/73 B.4, EPA 870.2500, JMAFF No 12 Nosan No 8147
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute dermal irritation study, the skin irritation/corrosion potential of BAS 310 I (batch COD-000166, purity: 99.3%) was tested. The intact clipped skin of 3 New Zealand White rabbits was exposed to 0.5 g of the unchanged test substance for 4 hours covered with a semi-occlusive dressing.
The cutaneous reactions were assessed immediately after removal of the patch, approximately 1, 24, 48 and 72 hours after removal of the patch and then in weekly intervals until day 14 after treatment.
Slight erythema, observed in all animals immediately after removal of the patch, increased to moderate in all animals within 1 hour. Moderate erythema persisted in one animal up to day 7 and decreased to slight erythema in two animals at the 24- hour reading. Slight erythema persisted in one of these animals until 72 hours. In one animal severe scaling was noticed on day 7. The cutaneous reactions were reversible in one animal within 48 hours, in another animal within 7 days and in the third animal within 14 days after removal of the patch.
Individual mean skin irritation scores (24 to 72 hours) for each of the three animals were:

- Erythema: 1.0-0.3-2.0
- Edema: 0.0 each

- Mean scores for erythema and edema: 1.1-0.0

Consequently, alpha-cypermethrin **does not show a relevant skin irritation potential** under the test conditions chosen.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 310 I

Description:	Solid; powder/white
Lot/Batch #:	COD-000166
Purity:	99.3 %
Stability of test compound:	Stable

2. Vehicle: The test substance was administered unchanged.

3. Test animals:

Species:	Rabbit
Strain:	New Zealand white A 1077 INRA (SPF)
Sex:	2 males / 1 female
Age:	ca. 6 months
Weight at dosing:	males: 3.60 and 3.70 kg, female: 3.80 kg
Source:	Centre Lago S. A., 01540 Vonnas, France
Acclimation period:	At least 5 days
Diet:	Kliba-Labordiät (Kaninchen & Meerschweinchenhaltung "GLP"), Provimi Kliba SA, Kaiseraugst, Basel, Switzerland (about 130 g/animal per day)
Water:	Tap water, ad libitum
Housing:	Single housing in stainless steel wire mesh cages with grating, floor area: 3000 cm²

Environmental conditions:

Temperature:	20 - 24 °C
Humidity:	30 - 70 %
Air changes:	Central air-conditioning
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 6 am to 6 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 22-Feb-2005 - 12-Apr-2005

2. In-vitro pre-test: No *in vitro* pre-test was conducted. *In vivo* data already existed.

3. Animal assignment and treatment:
The potential of BAS 310 I to cause acute dermal irritation or corrosion was assessed by a single topical application of 0.5 g of the unchanged test substance for 4 hours to the intact untreated skin of three New Zealand White rabbits using a patch of 2.5 cm x 2.5 cm. The test substance was covered with a test patch (Idealbinde, Pfaelzische Verbandstoff-Fabrik, Kaiserslautern) and Fixomull stretch (adhesive fleece, Beiersdorf AG). The test substance was removed at the end of the exposure period with Lutrol and Lutrol/water (1:1).
At least 24 hours before treatment, the dorsolateral part of the trunk of the animals was clipped. The cutaneous reactions were assessed immediately after removal of the patch, approximately 1, 24, 48 and 72 hours, on day 7 and maximally up to day 14 after removal of the patch.
Body weights were measured before application of the test substance and after the last reading. The animals were checked for mortality and morbidity twice on working days and once daily at weekends and on public holidays.

II. RESULTS AND DISCUSSION

Slight erythema (grade 1), observed in all animals immediately after removal of the patch, increased to moderate (grade 2) in all animals within 1 hour. Moderate erythema persisted in one animal up to day 7 and decreased to slight erythema (grade 1) in two animals at the 24-hour reading. Slight erythma persisted in one of these animals until 72 hours. In one animal severe scaling was noticed on day 7. The cutaneous reactions were reversible in one animal within 48 hours, in another animal within 7 days and in the third animal within 14 days after removal of the patch. Mean scores over 24, 48 and 72 hours for each animal were 1.0, 0.3 and 2.0 for erythema and 0.0 for edema. The overall 24 to 72 hour skin irritation scores were 1.1 for erythema and 0.0 for edema. Individual and mean irritation scores after 4 hour dermal application of BAS 310 I are presented in Table 5.2.4-1.

Table 5.2.4-1: Individual and mean skin irritation scores after 4 hour dermal application of BAS 310 I

SD: Study discontinued because the animal was free of symptoms

III. CONCLUSION

Based on the findings of this study, the BAS 310 I showed no relevant skin irritation potential to rabbits under the test conditions chosen.

Report:	CA 5.2.4/2 [redacted] 2005b BAS 310 I (Alpha-Cypermethrin) - Acute dermal irritation / corrosion in rabbits 2005/1011606
Guidelines:	OECD 404, EEC 2004/73 B.4, EPA 870.2500, JMAFF No 12 Nosan No 8147
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an acute dermal irritation study, the skin irritation/corrosion potential of BAS 310 I (batch COD-000165, purity: 98.8%) was tested. The intact clipped skin of 3 New Zealand White rabbits was exposed to 0.5 g of the unchanged test substance for 4 hours covered with a semi-occlusive dressing.
The cutaneous reactions were assessed immediately after removal of the patch, approximately 1, 24, 48 and 72 hours after removal of the patch and then in weekly intervals until day 14 after treatment.
Slight erythema was observed in all animals immediately after removal of the patch and persisted in one animal up to 24 hours. Moderate erythema was noted in two animals from 1 hour up to 48 hours and in one animal up to 72 hours. Moderate erythema increased to marked in one animal after 72 hours and decreased to moderate again on day 7. In this animal moderate edema was observed after 72 hours, too. Additionally scaling or severe scaling was noted in two animals on day 7. The cutaneous reactions were reversible within the 14 day observation period. Mean scores over 24, 48 and 72 hours for each animal were 2.0, 2.3 and 0.3 for erythema and 0.0, 0.7 and 0.0 for edema. The overall 24 to 72 hour skin irritation scores were 1.6 for erythema and 0.2 for edema. Individual mean skin irritation scores (24 to 72 hours) for each of the three animals were:

- Erythema: 2.0-2.3-0.3
- Edema: 0.0-0.7-0.0

- Mean scores for erythema and edema: 1.6 and 0.2, respectively.

Consequently, alpha-cypermethrin **does not show a relevant skin irritation potential** under the test conditions chosen.

III. CONCLUSION

Based on the findings of this study, the BAS 310 I showed no classification relevant skin irritation potential to rabbits under the test conditions chosen.

CA 5.2.5 Eye irritation

[redacted] **1993 (AL-410-003)**

Guidelines: In compliance with the test method B.5 of directive 92/69/EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

0.1 mL (45 mg) of alpha-cypermethrin (95.6%, cis1:cis2 ratio: 3:97) was instilled into the conjunctival sac of the eye of 6 New Zealand white rabbits.
All rabbits developed injection of the conjunctival blood vasculature and an ocular discharge within 1 hours of treatment. One animal showed injection of the conjunctival blood vasculature, chemosis sufficient to cause partial eversion of the eyelids and a slight ocular discharge. These effects reversed within 72 h. For corneal opacity and iris and a mean overall score of 0 was determined for the unwashed eye over the 24, 48 and 72 h reading time points. For erythema and chemosis values of 0.1 and 0.2 were determined.

Conclusion
Under the conditions of this study, alpha-cypermethrin was considered not to be eye-irritating.

[redacted] **1994b**

Guidelines: In compliance with the test method B.5 of directive 92/69/EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

0.1 g of alpha-cypermethrin (95 - 99.5%) was instilled into the conjunctival sac of the right eye of 3 New Zealand white rabbits. The eyes were rinsed 24 h after treatment.
For corneal opacity and iris an overall score of 0/0/0 was determined over the 24, 48 and 72 h reading time points. For conjunctival redness and chemosis values of 0.3/1.3/0 and 2/2.3/0.66 were determined.

Conclusion
Under the conditions of this study, alpha-cypermethrin was considered not to be eye-irritating.

Remark: The scores for chemosis would justify a classification for eye irritation. Similar effects were neither produced in the study of [redacted] 1993 nor in the studies presented newly in the AIR III process and therefore a classification for eye irritation is not considered justified for the nowadays produced material.

Report:	CA 5.2.5/1 [redacted] 2005c BAS 310 I (Alpha-Cypermethrin) - Acute eye irritation in rabbits 2005/1011571
Guidelines:	OECD 405, EEC 2004/73 B.5, EPA 870.2400, JMAFF No 12 Nosan No 8147
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In an eye irritation study, the eye irritation/corrosion potential of BAS 310 I (batch COD-000166, purity: 99.3%) was determined by instillation of 0.1 mL bulk volume (about 40 mg) of the unchanged test substance into the conjunctival sac of the right eye of three New Zealand White rabbits. The application of the test substance was performed in a stepwise procedure starting with one animal and supplementing two additional animals. About 1 hour after application the eye was rinsed with tap water.
The ocular reactions were assessed approximately 1, 24, 48 and 72 hours after the administration of the test substance.
Moderate conjunctival redness, observed in all animals 1 and 24 hours after application, decreased to slight in all animals at the 48-hour reading. Moderate conjunctival chemosis was noted in all animals at the 1-hour reading. Slight conjunctival chemosis was observed in one animal after 24 hours. Slight discharge was seen in all animals after 1 hour and in one animal after 24 hours. The ocular reactions were reversible in all animals within 72 hours.
Individual mean eye irritation scores (24 to 72 hours) for each of the three animals were:

- Corneal opacity: 0.0 each
- Iritis: 0.0 each
- Redness: 1.0 each
- Chemosis 0.3-0.0-0.0

- Mean scores for corneal opacity, iritis, redness and chemosis: 0-0-1-0.1

Consequently, alpha-cypermethrin is **not an eye irritant** under the conditions of this study.
.

1. Dates of work: 22-Feb-2005 - 12-Apr-2005

2. In-vitro pre-test: No *in vitro* pre-test was conducted. *In vivo* data already existed.

3. Animal assignment and treatment:
The potential of BAS 310 I to cause acute eye irritation/corrosion was assessed by instillation of 0.1 mL of the undiluted test substance (about 40 mg of the comminuted test substance) into the conjunctival sac of the right eye. The left eye, which remained untreated, served as the negative control. About 1 hours after application of the test substance, the treated eye was rinsed with 3 to 6 mL of hand warm tap water for 1 to 2 minutes using a syringe with a blunt probe. The ocular reactions were assessed approximately 1, 24, 48 and 72 hours and then in weekly intervals maximally up to day 28 after the administration of the test substance.
Body weights were determined shortly prior to application. The animals were checked for mortality and morbidity twice on working days and once daily at weekends and on public holidays.

II. RESULTS AND DISCUSSION

Moderate conjunctival redness (grade 2), observed in all animals 1 and 24 hours after application, decreased to slight (grade 1) in all animals at the 48-hour reading. Moderate conjunctival chemosis (grade 2) was noted in all animals at the 1-hour reading. Slight conjunctival chemosis (grade 1) was observed in one animal after 24 hours. Slight discharge (grade 1) was seen in all animals after 1 hour and in one animal after 24 hours. The ocular reactions were reversible in all animals within 72 hours. Mean scores calculated for each animal over 24, 48 and 72 hours were 0.0 for corneal opacity and for iris lesions, 1.0 for redness of the conjunctiva and 0.3, 0.0 and 0.0 for chemosis.
For details regarding the individual and mean scores as well as additional findings see Table 5.2.5-1.

Based on the findings of this study, BAS 310 I **does not show an eye irritation potential** to rabbits under the test conditions chosen.

CA 5.2.6 Skin sensitisation

[redacted] 1993 (AL-410-003)

Guidelines: In compliance with the test method B.6 of directive 84/449//EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

20 Dunkin Hartley guinea pigs received an intradermal induction of alpha-cypermethrin (batch 02156, drum 1085, 95.6%, cis1:cis2 ratio: 3:97) as 2% solution in corn oil:FCA. Percutaneous induction and challenge were performed with a 50% test substance solution in corn oil. A group of 10 animals served as control group.
None of the 20 test animals showed any positive response at either 24 or 48 h after removal of the challenge patches.

Conclusion
Under the conditions of this study, alpha-cypermethrin was considered not to be skin-sensitizing.

[redacted] 1994c

Guidelines: In compliance with the test method B.6 of directive 84/449//EEC
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.
20 Dunkin Hartley guinea pigs received an intradermal induction of alpha-cypermethrin (95% - 99.5%) 5% in propylene glycol. Percutaneous induction and challenge were performed with 50% test substance in petrolatum. A group of 20 animals served as control group.
An allergenicity score of 25% was reported resulting from erythema observed at 24 h after challenge in 4 animals (very slight erythema) and 1 animal (slight erythema).

Conclusion
Under the conditions of this study, alpha-cypermethrin was considered not to be skin-sensitizing.

Report:	CA 5.2.6/1 [redacted] 2005f BAS 310 I (Alpha-Cypermethrin) - Maximization test in guinea pigs 2005/1011608
Guidelines:	EEC 96/54 B 6, OECD 406, EPA 870.2600, JMAFF No 12 Nosan No 8147
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

BAS 310 I (batch: COD-000165, purity: 98.8%) was tested in a maximization test in female Dunkin Hartley guinea pigs (HsdPoc: DH). Based on the results of a pre-test, the intradermal induction was performed with a 5% test item preparation in 1% CMC-solution into the neck region of the animals. The epicutaneous induction (7 days after intradermal induction) and the challenge exposure (14 days after epicutaneous induction) were performed with a 50 % test item preparation. The study was performed in 5 control and 10 test group animals. Readings were performed 24 hours after the intradermal injection and 24 hours after removal of the patch with regard to epicutaneous induction. The challenge was carried out with the test substance preparation applied for 24 hours to the intact skin of the flank under occlusive conditions. 24 and 48 hours after removal of the patch, skin readings were performed. A positive control with a known sensitizer was not included into the study. However, studies with Alpha-Hexylcinnamaldehyde (techn. 85%) are regularly performed as reliability check in the laboratory and showed that the test system is able to detect sensitizing compounds under the laboratory conditions by showing a sensitization rate of 100% in the guinea pig strain.

The intradermal induction caused moderate and confluent to intense erythema and swelling at the injection sites of the test substance preparation in all test group animals. After the epicutaneous induction, incrustation, partially open (caused by the intradermal induction) could be observed in addition to moderate and confluent erythema and swelling in all test group animals. The challenge resulted in skin reactions in 0/5 control and 0/10 test group animals.

Based on the results of this study alpha-cypermethrin **does not have a sensitizing effect** on the skin of the guinea pig in the Maximization Test under the test conditions chosen.

(DocID 2005/1011608)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	BAS 310 I
Description:	Solid; powder/white
Lot/Batch #:	COD-000165
Purity:	98.8%
Stability of test compound:	Stable

2. Vehicle / Positive control:

Vehicles:
1% CMC (cleaned sodium carboxymethylcellulose) in doubly distilled water
Positive control: Alpha-Hexylcinnamaldehyde

3. Test animals:

Species:	Guinea Pig
Strain:	Dunkin Hartley, HsdPoc: DH
Sex:	female
Age:	6 - 8 weeks
Weight at dosing (mean):	424 - 507 g
Source:	Harlan Winkelmann, Gartenstr. 27, 33178 Borchen, Germany
Acclimation period:	14 days
Diet:	Kliba Labordiät (Kaninchen/ Meerschweinchen-Haltungsdiät) Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
Water:	Tap water, ad libitum
Housing:	Groups of 5 animals were housed in stainless steel wire mesh cages with plastic-coated grating, minimum floor area: 2000 cm²

Environmental conditions:

Temperature:	20 - 24 °C
Humidity:	30 - 70 %
Air changes:	Central air-conditioning
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 6 am to 6 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 11-Mar-2015 - 26-Apr-2005

2. Animal assignment and treatment:

The skin sensitizing potential of BAS 310 I was assessed using the Maximization Test based on the method of Magnusson and Kligman. For this, female guinea pigs were randomly allocated to groups. Five animals were used as control group animals and 10 animals in the test group. Based on the results of a pre-test, animals were intradermally induced with 5% test substance preparations. Epidermal induction and challenge were conducted with 50% test substance preparations. The homogeneity and the stability of the test substance in the vehicle were determined indirectly by the concentration control analysis. The fur was clipped at least 2 hours before each test item application at the appropriate application sites. If necessary, the fur was additionally clipped at least 2 hours before evaluation of the skin reactions.

3. Clinical observation:
Mortality was checked once each day. No detailed clinical examination of the individual animals was performed but any obvious signs of systemic toxicity and/or local inflammation at the application sites were recorded.

4. Body weights:
Individual body weights were determined on day 0 on the last day of observation.

5. Pre-test:
A 5% test substance preparation (TS in 1% CMC-solution in doubly distilled water) was intradermally injected to two animals. 6 intradermal injections were applied at the neck region of each animal: front row: 2 injections each of 0.1 mL Freund´s complete adjuvant without test item emulsified with 0.9 % aqueous NaCl-solution in a ratio of 1:1; middle row: 2 injections each of 0.1 mL of a test item preparation in vehicle at the selected concentration; back row: 2 injections each of 0.1 mL Freund's complete adjuvant / vehicle (1 : 1) with test item at the selected concentration. Skin reactions were assessed 24 hours after the beginning of the application. For detecting a possible influence on irritating effects of previous intradermal treatment with Freund's complete adjuvant, animals pretreated with Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1 : 1) each, in the same manner as intradermal pretest referring front row and back row without test substance about 3 weeks prior to the application of the test substance were used. 2 x 2 cm gauze patches (6 layers surgical gauze Ph. Eur. from Lohmann GmbH & Co. KG) containing 0.5 mL of test substance preparation (25 and 50% in 1% CMC-solution in doubly distilled water) were applied to the skin of the flanks under an occlusive dressing. The dressing consisted of rubberized linen patches (4 x 4 cm from Russka), patches of Idealbinde (5 x 5 cm from Pfälzische Verbandstoff-Fabrik) and Fixomull® Stretch (adhesive fleece) from Beiersdorf AG. The animals were exposed for 24 hours and skin readings were performed 1, 24 and 48 h after removal of the patch.

6. Main study – intradermal induction:
Based on the results of the pretest, test group animals received intradermal injections of 5% test substance preparations analogously to the intradermal pretest (see above). Control group animals received the same injections but with the test substance preparation being replaced by the vehicle.

7. Main study – epicutaneous induction:
One week after intradermal induction, 1 mL of the 50% test item preparation was applied to each test group animal under the same conditions as described in the epidermal pretest. The control animals were not treated since the 1% CMC-solution in doubly distilled water used as formulating agent was not expected to influence the result of the study.

8. Main study - challenge:
The challenge was carried out 14 days after the epicutaneous induction. 0.5 mL of the 50% test item preparation was applied to the test and control group animal. The animals were exposed under occlusive conditions as described above for 24 hours and skin readings were performed 24 and 48 h after removal of the patch.

9. Evaluation of results
The number of animals with skin findings at 24 and/or 48 hours after the removal of the patch was taken into account for the determination of the sensitization rate. The evaluation "sensitizing" results if at least 30% of the test animals exhibit skin reactions.

10. Positive controls
A positive control (reliability check) with a known sensitizer was not included in this study. However, a separate study with the positive control Alpha-Hexylcinnamaldehyde (techn. 85%) is regularly performed in the laboratory.

II. RESULTS AND DISCUSSION

A. PRE-TEST

Injections of a 5% test substance preparation in 1% CMC-solution in doubly distilled water caused moderate and confluent erythema and swelling. At the injection sites of a 5% test substance preparation in Freund's complete adjuvant/0.9% aqueous NaCl-solution (1 : 1) intense erythema and swelling were seen. After epidermal induction and challenge no skin findings were observed in the animals treated with 50% and 25% test substance preparations 24 and 48 hours after removal of the patch.

B. OBSERVATIONS

No abnormalities were observed during general observation.

C. BODY WEIGHTS

Body weight gain was not adversely affected during the course of the study.

D. SKIN REACTIONS AFTER INTRADERMAL INDUCTION

Injections of a 5% test item preparation in 1% CMC-solution in doubly distilled water caused moderate and confluent to intense erythema and swelling at the injection sites of the test substance preparation in all test group animals (see Table 5.2.6-1**:**).

Table 5.2.6-1: BAS 310 I - Skin reactions after intradermal induction

	left	3	2 E	3

E: Swelling

E. SKIN REACTIONS AFTER EPICUTANEOUS INDUCTION

The epicutaneous induction with a 50% test substance preparation in 1% CMC-solution in doubly distilled water led to incrustation, partially open (caused by the intradermal induction) and moderate and confluent erythema in all test group animals (see Table 5.2.6-2).

Table 5.2.6-2: BAS 310 I - Skin reactions after epicutaneous induction

417	2 E K
418	2 E K
419	2 E K
420	2 E K

E: Swelling; K: incrustation, partially open

F. SKIN REACTIONS AFTER CHALLENGE

The challenge with a 50% test substance preparation in 1% CMC-solution in doubly distilled water did not cause any skin reactions in animals of the control group and test group 24 and 48 hours after removal of the patch (see Table 5.2.6-3). Since no borderline results were observed, a 2nd challenge was not performed.

Table 5.2.6-3: BAS 310 I - Skin reactions after challenge

	Challenge			
Skin findings	**Control group**		**Test group**	
	24 h	**48 h**	**24 h**	**48 h**
Grade 0	5/5#	5/5	10/10	10/10

[#] x/y = number of findings / number of animals tested

G. POSITIVE CONTROL

The positive control Alpha-Hexylcinnamaldehyde showed a sensitization rate of 100% in the guinea pig strain. The results of the latest study conducted with the positive control are presented in Table 5.2.6-4.

Table 5.2.6-4: Skin reactions after challenge with the positive control

	Challenge			
Skin findings	**Alpha-Hexylcinnamaldehyde (techn. 85%) 5% in Lutrol® E 400**		**Vehicle Control: Lutrol® E 400**	
	24 h	**48 h**	**24 h**	**48 h**
Control group	0/5#	0/5	0/5	0/5
Test group	10/10	9/10	0/10	0/10

[#] x/y = number of positive reactions/number of animals tested (reading at 24 h and/or 48 h after the removal of the patch)

III. CONCLUSION

Based on the results of this study it is concluded that BAS 310 I does not have sensitizing properties in the guinea pig maximization test under the test conditions chosen. 0% of the animals were considered positive after challenge application.

Report:	CA 5.2.6/2 [redacted] 2005g BAS 310 I (Alpha-Cypermethrin) - Maximization test in guinea pigs 2005/1011572
Guidelines:	EEC 96/54 B 6, OECD 406, EPA 870.2600, JMAFF No 12 Nosan No 8147
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

BAS 310 I (batch: COD-000166, purity: 99.3%) was tested in a maximization test in female Dunkin Hartley guinea pigs (HsdPoc: DH). Based on the results of a pre-test, the intradermal induction was performed with a 5% test item preparation in 1% CMC-solution into the neck region of the animals. The epicutaneous induction (7 days after intradermal induction) and the challenge exposure (14 days after epicutaneous induction) were performed with a 50 % test item preparation. The study was performed in 5 control and 10 test group animals. Readings were performed 24 hours after the intradermal injection and 24 hours after removal of the patch with regard to epicutaneous induction. The challenge was carried out with the test substance preparation applied for 24 hours to the intact skin of the flank under occlusive conditions. 24 and 48 hours after removal of the patch, skin readings were performed. A positive control with a known sensitizer was not included into the study. However, studies with Alpha-Hexylcinnamaldehyde (techn. 85%) are regularly performed as reliability check in the laboratory and showed that the test system is able to detect sensitizing compounds under the laboratory conditions by showing a sensitization rate of 100% in the guinea pig strain.

The intradermal induction caused moderate and confluent to intense erythema and swelling at the injection sites of the test substance preparation in all test group animals. After the epicutaneous induction, incrustation, partially open (caused by the intradermal induction) could be observed in addition to moderate and confluent erythema and swelling in all test group animals. The challenge resulted in skin reactions in 0/5 control and 0/10 test group animals.

Based on the results of this study alpha-cypermethrin **does not have a sensitizing effect** on the skin of the guinea pig in the Maximization Test under the test conditions chosen.

B. STUDY DESIGN AND METHODS

1. Dates of work: 11-Mar-2015 - 28-Apr-2005

2. Animal assignment and treatment:
The skin sensitizing potential of BAS 310 I was assessed using the Maximization Test based on the method of Magnusson and Kligman. For this, female guinea pigs were randomly allocated to groups. Five animals were used as control group animals and 10 animals in the test group. Based on the results of a pre-test, animals were intradermally induced with 5% test substance preparations. Epidermal induction and challenge were conducted with 50% test substance preparations. The homogeneity and the stability of the test substance in the vehicle were determined indirectly by the concentration control analysis. The fur was clipped at least 2 hours before each test item application at the appropriate application sites. If necessary, the fur was additionally clipped at least 2 hours before evaluation of the skin reactions.

3. Clinical observation:
Mortality was checked twice each workday and once on Saturdays, Sundays and on public holidays. No detailed clinical examination of the individual animals was performed but any obvious signs of systemic toxicity and/or local inflammation at the application sites were recorded.

4. Body weights:
Individual body weights were determined on day 0 on the last day of observation.

5. Pre-test:
A 5% test substance preparation (TS in 1% CMC-solution in doubly distilled water) was intradermally injected to two animals. 6 intradermal injections were applied at the neck region of each animal: front row: 2 injections each of 0.1 mL Freund´s complete adjuvant without test item emulsified with 0.9 % aqueous NaCl-solution in a ratio of 1:1; middle row: 2 injections each of 0.1 mL of a test item preparation in vehicle at the selected concentration; back row: 2 injections each of 0.1 mL Freund's complete adjuvant / vehicle (1 : 1) with test item at the selected concentration. Skin reactions were assessed 24 hours after the beginning of the application. For detecting a possible influence on irritating effects of previous intradermal treatment with Freund's complete adjuvant, animals pretreated with Freund's complete adjuvant / 0.9% aqueous NaCl-solution (1 : 1) each, in the same manner as intradermal pretest referring front row and back row without test substance about 3 weeks prior to the application of the test substance were used. 2 x 2 cm gauze patches (6 layers surgical gauze Ph. Eur. from Lohmann GmbH & Co. KG) containing 0.5 mL of test substance preparation (25 and 50% in 1% CMC-solution in doubly distilled water) were applied to the skin of the flanks under an occlusive dressing. The dressing consisted of rubberized linen patches (4 x 4 cm from Russka), patches of Idealbinde (5 x 5 cm from Pfälzische Verbandstoff-Fabrik) and Fixomull® Stretch (adhesive fleece) from Beiersdorf AG. The animals were exposed for 24 hours and skin readings were performed 1, 24 and 48 h after removal of the patch.

6. Main study – intradermal induction:
Based on the results of the pretest, test group animals received intradermal injections of 5% test substance preparations analogously to the intradermal pretest (see above). Control group animals received the same injections but with the test substance preparation being replaced by the vehicle.

7. Main study – epicutaneous induction:
One week after intradermal induction, 1 mL of the 50% test item preparation was applied to each test group animal under the same conditions as described in the epidermal pretest. The control animals were not treated since the 1% CMC-solution in doubly distilled water used as formulating agent was not expected to influence the result of the study.

8. Main study - challenge:
The challenge was carried out 14 days after the epicutaneous induction. 0.5 mL of the 50% test item preparation was applied to the test and control group animal. The animals were exposed under occlusive conditions as described above for 24 hours and skin readings were performed 24 and 48 h after removal of the patch.

9. Evaluation of results
The number of animals with skin findings at 24 and/or 48 hours after the removal of the patch was taken into account for the determination of the sensitization rate. The evaluation "sensitizing" results if at least 30% of the test animals exhibit skin reactions.

10. Positive controls
A positive control (reliability check) with a known sensitizer was not included in this study. However, a separate study with the positive control Alpha-Hexylcinnamaldehyde (techn. 85%) is regularly performed in the laboratory.

II. RESULTS AND DISCUSSION

A. PRE-TEST

Injections of a 5% test substance preparation in 1% CMC-solution in doubly distilled water caused moderate and confluent erythema and swelling. At the injection sites of a 5% test substance preparation in Freund's adjuvant/0.9% aqueous NaCl-solution (1 : 1) intense erythema and swelling were seen. No skin findings were observed in the animals treated with a 50% and 25% test substance preparation 24 and 48 hours after removel of the patch.

B. OBSERVATIONS

No abnormalities were observed during general observation.

C. BODY WEIGHTS

Body weight gain was not adversely affected during the course of the study.

D. SKIN REACTIONS AFTER INTRADERMAL INDUCTION

Injections of a 5% test item preparation in 1% CMC-solution in doubly distilled water caused moderate and confluent to intense erythema and swelling at the injection sites of the test substance preparation in all test group animals (see Table 5.2.6-5).

Table 5.2.6-5: BAS 310 I - Skin reactions after intradermal induction

	left	3	2 E	3

E: Swelling

E. SKIN REACTIONS AFTER EPICUTANEOUS INDUCTION

The epicutaneous induction with a 50% test substance preparation in 1% CMC-solution in doubly distilled water led to incrustation, partially open (caused by the intradermal induction) and moderate and confluent erythema in all test group animals (see Table 5.2.6-6).

720	2 E K

E: Swelling; K: incrustation, partially open

F. SKIN REACTIONS AFTER CHALLENGE

The challenge with a 50% test substance preparation in 1% CMC-solution in doubly distilled water did not cause any skin reactions in animals of the control group and test group 24 and 48 hours after removal of the patch (see Table 5.2.6-7). Since no borderline results were observed, a 2nd challenge was not performed.

Table 5.2.6-7: BAS 310 I - Skin reactions after challenge

	Challenge			
Skin findings	**Control group**		**Test group**	
	24 h	**48 h**	**24 h**	**48 h**
Grade 0	5/5#	5/5	10/10	10/10

x/y = number of findings / number of animals tested

G. POSITIVE CONTROL

The positive control Alpha-Hexylcinnamaldehyde showed a sensitization rate of 100% in the guinea pig strain. The results of the latest study conducted with the positive control are presented in Table 5.2.6-8.

Table 5.2.6-8: Skin reactions after challenge with the positive control

	Challenge			
Skin findings	**Alpha-Hexylcinnamaldehyde (techn. 85%) 5% in Lutrol® E 400**		**Vehicle Control: Lutrol® E 400**	
	24 h	**48 h**	**24 h**	**48 h**
Control group	0/5#	0/5	0/5	0/5
Test group	10/10	9/10	0/10	0/10

x/y = number of positive reactions/number of animals tested (reading at 24 h and/or 48 h after the removal of the patch)

III. CONCLUSION

Based on the results of this study it is concluded that BAS 310 I does not have sensitizing properties in the guinea pig maximization test under the test conditions chosen. 0% of the animals were considered positive after challenge application.

CA 5.2.7 Phototoxicity

Report: CA 5.2.7/1
Cetto V.,Landsiedel R., 2013a
BAS 310 I (Alphacypermethrin) - In vitro 3T3 NRU phototoxicity test
2013/1389105

Guidelines: OECD 432 (2004) In vitro 3T3 NRU Phototoxicity test, (EC) No 440/2008 of 30 May 2008 laying down test methods pursuant to (EC) No 1907/2006 of European Parliament and of Council on the REACH - Part B No. B.41 No. L 142

GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

Alpha-Cypermethrin (Batch L80-24; purity 99.4%) was tested for its ability to induce phototoxic effects in Balb/c 3T3 cells in vitro. The photo-cytotoxicity was estimated by the means of the Neutral Red Uptake (NRU) method. A single experiment was carried out with and without UVA irradiation. Vehicle and positive controls were included into the study. Based on the range-finding phototoxicity test the same concentrations were used in the main experiment with and without Irradiation: 4.6 - 10 - 21.5 - 46.4 - 100 - 215.4 - 464.2 - 1000 µg/mL.
Test substance precipitation in culture medium at the end of treatment was observed at 215.4 µg/mL and above in the absence and presence of UVA irradiation. In addition, changes in cell morphology were observed at the end of exposure period at 215.4 µg/mL and above without and with irradiation. After treatment with the test substance, no cytotoxic effects indicated by Neutral Red absorbance values of below 50% of control were observed in the Main Experiment in the absence and the presence of UVA irradiation. Therefore, no EC_{50} values could be calculated. Based on these observations a formal PIF = *1 has to be used to characterize the result. The positive control chlorpromazine led to the expected cytotoxicity both with and without UVA irradiation (PIF: 60.1).

Thus, under the experimental conditions of this study, alpha-cypermethrin is considered **not to be a phototoxic** substance in the in vitro 3T3 NRU Phototoxicity Test using Balb/c 3T3 cells.

(DocID 2013/1389105)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material BAS 310 I

Description: Solid; white

Lot/Batch #: L80-24

Purity: 99.4% (tolerance ± 1.0%) (see Certificate of Analysis, study code ASAP13_123)

Stability of test compound: The stability of the test substance under storage conditions over the test period was guaranteed until 01 Sep 2019 by the sponsor, and the sponsor holds this responsibility. The homogeneity of the test substance was ensured by the high purity and by mixing prior to preparation of test substance solutions.
The stability of the test substance in the vehicle DMSO was not determined analytically.

Solvent used: DMSO

2. Control Materials:

Vehicle control: The vehicle control cultures with and without irradiation only contained the vehicle used for the test substance/positive control at the same concentration and volume as used for the test substance and the positive control.

Solvent/final concentration: DMSO 1% (v/v) in PBS

Positive control compounds: Chlorpromazine (CPU) was dissolved in DMSO

A complete 96-well plate containing 8 concentrations was performed in parallel to demonstrate sensitivity of the test method.

Without irradiation	1.9-3.8-7.5-15-30-60-90-180 µg/mL
With irradiation	0.03-0.05-0.1-0.2-0.4-0.8-1.6-3.2 µg/mL

3. Test organisms: The BaIb/c 3T3, clone A31, cell line was isolated from the muscle tissue of mouse embryo. This fibroblast cell line has a high proliferation rate (doubling time 16 - 20 hours) and a high plating efficiency (>70%)) of untreated cells both necessary for the appropriate performance of the study. The Balb/c 3T3 cell line which was used in this experiment was obtained from the “European Collection of Cell Cultures” Salisbury, Wiltshire SP4 OJG, UK (date 09 Aug 2006) and is stored at -196°C (liquid nitrogen).

4. Culture media and reagents:

Culture medium:	Dulbecco's Modified Eagle's Medium (DMEM) supplemented with - 10% (v/v) newborn calf serum (NCBS) - 4 mM L-glutamine - 100 IU penicillin - 100 µg/mL streptomycin
Neutral Red solution:	- 0.4 g Neutral Red powder (NR; Sigma N4638) - 100 mL deionized water
Neutral Red medium:	- 1 mL Neutral Red solution - 79 mL culture medium (DMEM incl. supplements) Incubated overnight at 37° C with 5% CO_2 and filtered with a 0.22 µm filter prior to use.
Other solutions and reagents:	- phosphate buffered saline (PBS) without Ca/Mg - trypsin/EDTA solution (0.05%; 0.02%) - Neutral Red desorb solution (1 mL acetic acid, 50 mL ethanol, 49 mL deionized water)

5. Irradiation source: The Sol 500 solar simulator (Dr. Hönle AG, 82166 Gräfelfing, Germany) used with filter H1 produced wavelength > 320 nm. The exposure rates were determined with UV-meter RM-21 (Dr. Gröbel GmbH, 76275 Ettlingen, Germany).

6. Test concentrations:

Pretest:	Up to 1000 µg/mL with and without irradiation.
NRU test conditions:	An appropriate amount of test article substance was taken up in the vehicle, shaken thoroughly and diluted in accordance with the planned doses under light protection conditions immediately before administration. The experiment was performed in 96 well plates in one experiments (6 replicates per concentration with and without irradiation; two plates per substance (test substance or positive control) were prepared.) The test substance concentrations were: Without: 4.6; 10.00; 21.5; 46.4; 100.0, 215.4, 464.2, 1000.0 µg/mL With: 4.6; 10.00; 21.5; 46.4; 100.0, 215.4, 464.2, 1000.0 µg/mL

B. TEST PERFORMANCE:

1. Dates of experimental work: 05-Nov-2013 - 29-Nov-2013

2. Treatment and NRU Phototoxicity test:

Two 96 well-plates per substance (test substance or positive control) were used for cultivation of cells (1.5 x 10^5 cells/well). After an attachment period of about 24 hours the cells were washed once with 100 µL PBS and subsequently treated with the respective substance (8 concentrations each with 6 replicates of the test substance or the positive control) and the vehicle control in parallel for 1 hour in the dark (5% (v/v) CO_2, ≥90% humidity; 37° C). Then, one microtiterplate per substance was irradiated for 50 minutes with UVA (UV intensity underneath the lid 1.5 - 2.1 mW/cm^2 = 5 J/cm^2) whereas the respective reference plate was kept in the dark for the same period. After test substance removal and washing step (100 µL PBS) the cells were incubated in culture medium overnight. The medium was removed after 24 hours, the cells washed again, 100 µL medium containing 50 µg/mL Neutral red was added and the plates were incubated for another 3 hours. Each step was performed under light protected conditions in the lab to prevent uncontrolled photo activation. Afterwards, the cells were washed and the dye was extracted by Neutral Red desorb solution. Cytotoxicity was determined by measuring the Neutral Red Uptake using a microplate reader (Perkin Elmer, Waltham, Massachusetts, US; Wallac 1420 multilabel counter) equipped with a 550 nm filter to read the absorption of the extracted dye. The absorption shows a linear relationship with the number of surviving cells.

3. Evaluation/Assessment

For the assessment of the phototoxic potential of a compound two prediction models are currently available:

- The Photo-Irritancy-Factor Prediction model for substances which allow the comparison of two equi-effective concentrations (EC_{50}) in the concurrently performed experiments in the presence and absence of light. This model includes the special case of absence of cytotoxicity in the presence and absence of light for substances obviously showing no phototoxic potential (see below).
- The Mean Photo Effect prediction model which is used if no equi-effective concentrations (EC_{50}) are obtained in the absence and presence of UV light. This special cases do not apply to this study. Even though described in the report this case is not described in this summary.

3.1 Cytotoxicity

The mean absorbance values obtained for each test group of every plate were used to calculate the percentage of cell viability relative to the respective vehicle control, which is arbitrariliy set at 100 %.

$$Cytotoxicity\,[\%] = \frac{\text{Absorbance}_{\text{mean of the test group}}}{\text{Absorbance}_{\text{mean of the vehiclecontrol}}} \times 100$$

In case of cytotoxicity, an EC_{50} value (Inhibition concentration 50% relative to the respective vehicle control) was calculated by a linear interpolation method (linear dose-response curve).

3.2 Photo-Irritancy-Factor

If no cytotoxicity occurs to determine an EC_{50} value in the concurrently performed experiments in the absence and presence of UV light up to the highest applied test concentration it has to be considered that the test substance has no phototoxic potential.

In this case, a formal PIF = *1 is used to characterize the result:

$$PIF = *1 = \frac{C\max(-UVA)}{C\max(+UVA)}$$ resulting in the following classification rule:

PIF = *1	no phototoxic potential predicted

3.3 Other parameters

pH:
The pH was measured at least for the two top doses and for the vehicle controls with and without irradiation.

Osmolarity:
Osmolarity was measured at least for the two top doses and for the vehicle controls with and without irradiation.

Solubility:
Test substance precipitation was checked immediately after treatment and at the end of treatment.

Cell morphology:
Test cultures of all test groups were examined microscopically before staining with NRU, which allows conclusions to be drawn about attachment of the cells.

4. Statistics:

No special statistical tests were performed.
Mean absorbance values and standard deviations were calculated from the single values using calculation software (e.g. MS Excel). The calculations were made using the unedited values. For the report the values were rounded, therefore there may be deviations in the given relative values. If technical errors occurred in single wells (outlier) at least 4 single values per test group were sufficient for calculating reliable mean values. Outliers are defined as values that have half or double the value of the respective mean.

5. Acceptance criteria:

The assay has to be considered valid if the following criteria are met:

- The vehicle control needs to fulfill the following criteria:
  - The mean OD550 value (with and without UVA irradiation) should be ≥ 0.3.
  - Cell viability after irradiation should be at least 80% of the concurrent non-irradiated vehicle control.
  - The standard deviation of the mean values of both vehicle control rows should not exceed ± 15%.
- The positive control chlorpromazine needs to fulfill the following criteria:
  - the EC50 value should be in the ranges:
    With irradiation (+UVA): 0.1 - 2.0 µg/mL
    Without irradiation (-UVA): 7.0 - 90.0 µg/mL
  - and the PIF ≥ 6.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

Osmolarity and pH values were not influenced by test substance treatment. In this study, in the absence and the presence of UVA irradiation precipitation in culture medium was observed at test substance concentrations of 215.4 µg/mL and above. In addition, changes in cell morphology were observed at the end of exposure period at 215.4 µg/mL and above without and with irradiation.

B. CYTOTOXICITY OF THE TEST SUBSTANCE

After treatment with the test substance, no cytotoxic effects indicated by Neutral Red absorbance values of below 50% of control were observed in the main experiment in the absence and the presence of UVA irradiation. Therefore, no EC50 values could be calculated. Based on these observations a formal PIF = *1 has to be used to characterize the result.

Table 5.2.7-1: Mean relative cytotoxicity of BAS 310 I with and without UVA irradiation in Balb 3T3 cells

Test group	UVA irradiation*	Precipitation**	Mean $OD_{corr.}$ ***	Cytotoxicity [% of control]
Vehicle control (1% DMSO)	-	-	0.359	100.0

C. CYTOTOXICITY OF THE POSITIVE CONTROL

After treatment with the positive control chlorpromazine clear cytotoxic effects indicated by Neutral Red absorbance values of below 50% of control were observed in the absence and the presence of UVA irradiation at least in the highest applied concentrations.
Without UVA irradiation, there was a decrease in the cell number from 60.0 µg/mL (EC_{50}: 35.4 µg/mL) onward. With UVA irradiation, there was a decrease in the cell number at 0.8 µg/mL (EC_{50}: 0.6 µg/mL) and above. Based on the EC_{50} values a PIF of 60.1 (phototoxic potential) was obtained (see Table 5.2.7-2).

Table 5.2.7-2: Mean relative cytotoxicity of Chlorpromazine with and without UVA irradiation in Balb/c 3T3 cells

III. CONCLUSIONS

According to the results of the present study, alpha-cypermethrin is considered **not to be a phototoxic** substance in the in vitro 3T3 NRU Phototoxicity Test.

CA 5.3 Short-Term Toxicity

Studies evaluated in the draft monograph of rapporteur member state Belgium of Sep. 1999:
Short-term toxicity of alpha-cypermethrin was evaluated in subacute and subchronic studies (rat, mouse, dog) and all relevant data have been reviewed during the last Annex I inclusion process by European authorities and Belgium as Rapporteur Member State (European Commission Peer Review Program). All studies are scientifically valid; however, partially the studies have been conducted before the release of study guidelines and are without GLP according to the usual practice in those days. The studies are, for the convenience of the reviewer, listed in Table 5.3-1., and brief summaries were extracted from the monograph of alpha-cypermethrin and are provided under the respective chapters.

For several studies the achieved dose was newly calculated on the basis of data given in the respective report whereas in the former evaluation process the dose was estimated based on simple conversion factors. For the convenience of the reviewer the NOAEL is given in the Table as former estimated value and as newly calculated value.

The summary of the short-term toxicity studies from the DAR of alpha-cypermethrin (1999) is still valid, except for the respective achieved dose, which is amended in square brackets: “The short-term repeated dose exposure tests allow the hazard assessment, identification and dose-response, of alpha-cypermethrin.
Oral administration of alpha-cypermethrin primarily causes neurotoxicity in rats, mice and dogs, producing symptoms similar to those observed in the acute experiment. Doses that produce CNS effects also influence the general well-being of the animal. At the MTD, axonal degeneration has been seen in the rat. Above the MTD, hepatotoxicity is observed in the mouse.
The lowest NOAEL was 2.3 mg/kg bw/d [newly calculated: 3.5 mg/kg bw] (dog, 90 day) and 1.5 mg/kg bw/day [newly calculated: 2.0 mg/kg bw] (dog, 1 year).
Short term, repeated dose administration via inhalation (14 days), mainly produced local inflammatory reactions in the airways, compatible with the airway irritation seen in the acute inhalation experiment. These already appeared at exposure concentrations of 0.0028 mg/l. The absence of systemic effects is compatible with the low dose, 2.44 mg/kg bw/day, generated by the highest exposure concentration. Short term, repeated dose, dermal administration (21 days) to rabbits, did not show adverse effects.”

Table 5.3-1: Summary of already peer-reviewed alpha-cypermethrin short-term toxicity studies as available in the DAR (1999)

Study	Dosages (mg/kg bw/ day)	NOAEL (mg/kg bw/day)	Main adverse effect	Reference

[1] These studies are not BASF proprietary, but owned by Gharda, Chemical Ltd. Bombay, a further notifier for Annex I listing of alpha-cypermethrin in 1999.
[2] This studies formally shows the lowest NOAEL value but is considered less accurate than the 90-day feeding study in Beagle dogs AL-425-005. Therefore this NOAEL was not considered in the endpoint definition.
* No GLP study;

Studies submitted in this AIR 3 dossier (not yet peer-reviewed):
There is one 90-day study performed in 1994 that was not submitted in the former registration process under the aegis of Cyanamid. This feeding study contains a complete neurotoxic evaluation and is therefore described in detail in KCA 5.7. Furthermore a 15 day adult male rat assay was performed to address the endocrine potential of alpha-cypermethrin and potentially effects on sperm parameters. This study is described in detail in KCA 5.8.3.

Table 5.3-2: Summary of not yet reviewed alpha-cypermethrin short-term toxicity studies

Study	Dosages (mg/kg bw/ day)	NOAEL (mg/kg bw/day)	Main adverse effect	Reference

n.a.: not applicable- These studies do not mention a NOAEL level.

However, under consideration of the general toxicity parameters these studies do not change the overall risk assessment, which is still valid to be performed based on the NOAEL from the 1-year dog study, as the species which showed overall the lowest NOAEL.

Based on the available studies, the following endpoints were determined in the Annex I listing of alpha-cypermethrin in 2004.

Short term toxicity

Target / critical effect:	Irritation secondary to systemic toxicity (dogs)
Lowest relevant oral NOAEL/NOEL	1 year dog study: 60 ppm (1.5 mg/kg bw/day); R48/22 90 day dog study: 90 ppm (2.3 mg/kg bw/day)
Lowest relevant dermal NOAEL/NOEL	No data – not required
Lowest relevant inhalation NOAEL/NOEL	6h/day; 5 d/week, 3 week rat: >0.029 mg/L (no systemic effects, only local inflammatory effects)

Based on the newly calculated achieved dose at the respective NOAELs in the 90 day and 52-week feeding dog studies the following endpoints are proposed in the Annex renewal process:

Short term toxicity

Target / critical effect:	Irritation secondary to systemic toxicity (dogs)
Lowest relevant oral NOAEL/NOEL	1 year dog study: 60 ppm (**2.0** mg/kg bw/day); STOT RE 2 (H373) 90 day dog study: 90 ppm (**3.5** mg/kg bw/day)
Lowest relevant dermal NOAEL/NOEL	No data – not required
Lowest relevant inhalation NOAEL/NOEL	6h/day; 5 d/week, 3 week rat: >0.029 mg/L (no systemic effects, only local inflammatory effects)

CA 5.3.1 Oral 28-day study

Rat, 5 week feeding study, 0, 25, 100, 200, 400 and 800 ppm (AL-420-003)

Guidelines: Not fully in compliance with the test method B.7 of directive 92/69/EEC. This study is a Range finder
Deviations: The duration was longer than 28 days
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

Groups of 5 male and 5 female Wistar rats per dose group received alpha-cypermethrin (batch: OCD/7: ST 81/002; purity 96.5%) at dietary doses of 0, 25, 100, 200, 400 and 800 ppm for 5 weeks.

Rats administered 25, 100 and 200 ppm alpha-cypermethrin did not show treatment-related effects.
Feeding of 800 ppm alpha-cypermethrin to rats of both sexes for five weeks produced abnormal gait and increased sensitivity to noise. Abnormal gait was recorded only in one male at 400 ppm. Decreases of food intake and bodyweight were observed in rats of both sexes fed with 400 and 800 ppm alpha-cypermethrin.
Some haematological findings were seen in males at 400 and 800 ppm and females at 800 ppm. Changes in blood chemistry were considered to be a consequence of alterations in hepatic protein metabolism associated with the reduced nutritional status of the animals. Urinalysis did not reveal significant differences.
Increases in adjusted organ weights at 400 and 800 ppm were considered to be an adaptive response to increased functional demands associated with treatment. No significant treatment-related macroscopic abnormalities were identified at necropsy. Histological examination revealed no significant treatment induced effects other than axonal degeneration in the sciatic nerves of one male of the 800 ppm group killed due to severe neurological disturbance. There was no evidence of axonal degeneration in the sciatic nerves in either sex fed 400 ppm test substance.

Conclusion
Based on the described findings at 400 and 800 ppm the NOAEL in this study was identified at 200 ppm.

<u>New calculation of substance intake at NOAEL:</u>
No conversion from Concentration [ppm] to Dose [mg/kg bw/day] was done in the study report although food consumption and body weight were determined. In the monograph the dose was estimated based on a conversion factor of 10 resulting in 2.5, 10, 20, 40 and 80 mg/kg bw/day substance intake for 25, 100, 200, 400 and 800 ppm, respectively. Since the relevant values are available and well-documented in the report of the study, the group substance intake in “mg/kg bw/day” is newly calculated based on weekly values according the following equation:
Mean Substance intake [mg/kg bw/day] = Concentration (ppm) x (Mean (weekly group food consumption / weekly group mean body weight)/7 (see Table 5.3.1-1). The last week was not included due to food restrictions. The resulting values were already submitted in the biocide registration process for alpha-cypermethrin (Rapporteur: Belgium) and were considered acceptable.

Table 5.3.1-1: Substance Intake values at the NOAEL taken from the DAR (1999) and newly calculated based on data in the report

Dose (ppm)	estimated Substance Intake (mg/kg bw/day)	calculated Substance Intake (mg/kg bw/day)
200 (NOAEL)	Male: 20 Female: 20	Male:17.9 Female: 20.0

Rat, 6 week feeding study, 0, 50, 200, 800 and 1200 ppm (1993, AL-420-006)

Guidelines: Not fully in compliance with the test method B.7 of directive 92/69/EEC. This study is a Range finder.
Deviations: The duration was longer than 28 days
GLP: No
Acceptance: The study was considered acceptable in the EU registration process 1999.

Groups of 5 male and 5 female Crl:CD BR rats per dose group received alpha-cypermethrin (batch: 02156; drum 1085; purity 95.6%) at dietary doses of 0, 50, 200, 800 and 1200 ppm for 6 weeks.

Rats of both sexes fed 1200 ppm and males fed 800 ppm alpha-cypermethrin were sacrificed during weeks 2 to 4 because of severe treatment related clinical signs characteristic for pyrethroid neurotoxicity. The signs were characterized by changes in gait, hunched posture, abasia and hypersensitivity. Signs of gait changes, limb position, hypersensitivity and increased reactivity to stimuli were also observed in the functional observational battery (FOB) during week 2 in rats of both sexes fed 1200 ppm and males fed 800 ppm. Gait changes were also observed in the females received 800 ppm test substance during week 6. There were no statistically significant changes in fore or hind limb grip strength or hind limb landing foot splay.
Throughout the study rats of both sexes fed 1200 and 800 ppm test substance had lower mean body weight and food intake compared to controls.

There were only minor changes in haematology and clinical chemistry parameters in the males receiving 200 ppm and females fed with 800 ppm alpha-cypermethrin.

Increased absolute organ weights were not seen when adjusted for terminal body weight and considered to reflect terminal body weight reduction. There were no macroscopic treatment-related findings. Stress related histopathological findings were confined to lymphocyte depletion of the thymus in the decedent rats in the 800 and 1200 ppm treated groups and two surviving females fed with 800 ppm test substance. There were no significant microscopic findings in the nervous system or muscle tissues.

Conclusion
Based on the described findings at 800 and 1200 ppm the NOAEL in this study was identified at 200 ppm.

New calculation of substance intake at NOAEL:
No conversion from Concentration [ppm] to Dose [mg/kg bw/day] was done in the study report although food consumption and body weight were determined. In the monograph the dose was estimated based on a conversion factor. This estimated intake at the NOAEL was replaced by calculated substance intake values (see description under study AL-420-003). Thereby the following substance intake values at the NOAEL were calculated (see Table 5.3.1-2). The last week was not included due to food restrictions.

Table 5.3.1-2: Substance Intake values at the NOAEL taken from the DAR (1999) and newly calculated based on data in the report

Dose (ppm)	estimated Substance Intake (mg/kg bw/day)	calculated Substance Intake (mg/kg bw/day)
200	Male:20 Female: 20	Male:17.6 Female: 20.2

Mouse, 29-day feeding study, 0, 200, 400, 800, 1200, 1600ppm (1993, AL-420-005)

Guidelines: In compliance with the test method B.7 of directive 92/69/EEC. This study is a Range finder
GLP: Yes
Acceptance: The study was considered acceptable in the EU registration process 1999.

Groups of eight male and eight female CD-1 mice received alpha cypermethrin via the diet, at concentrations of 200, 400, 800, 1200, or 1600 ppm for 29 days. This study was conducted to assess the toxicity of alpha cypermethrin and to determine suitable dose levels to be used in longer-term studies. A similarly constituted control group received untreated diet.

One female receiving 1200 ppm and one male receiving 1600 ppm were sacrificed in extremis during the treatment period following signs of neurologic disturbances; these deaths were considered to be related to treatment. One male receiving 1200 ppm died without ante mortem signs on day 16; however its death could not readily be attributed to treatment.

Clinical signs of toxicity including ungroomed coats, ataxia/abnormal gait, overactivity and/or hunched posture were observed in animals receiving 1200 or 1600 ppm. At 800 ppm, ungroomed coats were observed in four males and three females and abnormal gait was observed in one female.
Significantly reduced overall body weight gains, when compared to the controls, were seen in males and females receiving 1600 and 1200 ppm, and in females receiving 800 ppm. The effects on overall weight gains were generally a consequence of weight loss or significantly reduced weight gains during the first one or two weeks of treatment, however gains during weeks 3 and 4 in males and during week 4 in females receiving 800 ppm or more tended to be lower than the controls.

When compared with the controls, food intake was reduced during the first two weeks in males receiving 1200 or 1600 ppm and during the first week in females receiving 1200 ppm. Overall, food consumption was comparable between treated and control animals. Reduced food conversion efficiency, when compared to controls, was observed only in animals exhibiting decreased weight gains.
Significantly reduced lymphocyte counts, in comparison with those of the controls after adjustment for outlying control values, were seen after 24 days in males receiving 1600 ppm. No significant hematologic effects were seen in treated females. After 29 days of treatment, increased plasma alanine and aspartate aminotransferase activities were seen in males receiving 1200 or 1600 ppm. Small, but statistically significant, reductions in total protein and albumin concentrations, with a concomitant reduction in albumin to globulin ratios, were seen in males receiving 1600 ppm.
Terminal body weights were significantly lower for males and females treated at 800, 1200 and 1600 ppm. Kidney-to-body weight ratios for males fed 800, 1200 and 1600 ppm and for females fed 800 and 1200 ppm were increased compared to those of controls. It is likely that these findings resulted from decreased body weights observed for the animals in these dose groups. In addition, there were no changes in absolute kidney weights for either males or females at any dose level.
There were no macroscopic or microscopic findings which could be attributed to treatment with alpha cypermethrin.

Conclusion:
Based on the described findings at 1600, 1200 and 800 ppm the NOAEL in this study was identified at 400 ppm, corresponding to 55.9 mg/kg bw/d for male and 73.1 mg/kg bw/d for female mice as given in the report.

Dog, 14-day oral administration, 0, 1.25, 2.5, 5, 10, 20, 40 mg/kg bw (1988a, [redacted]

Guidelines: Not fully in compliance with the test method B.7 of directive 92/69/EEC. This study is a Range finder
Deviations: Rat is the preferred species: low number of animals, duration shorter than 28 day, incomplete description of experimental protocol and results.
GLP: No
Acceptance: The study was considered acceptable in the EU registration process 1999.

One female and one male Mongrel dog per dose group received alpha-cypermethrin (batch: not given; purity 95 – 99.5%) received orally 1.25, 2.5, 5, 10, 20 and 40 mg/kg bw for 14 days.

No significant toxic symptoms were exhibited by control and treated animals except vomiting reported at the two highest doses. No mortality, normal body weight gain, relative values of organ weights of treated animals were normal and no significant gross pathological effect were noted. Administration of test material was discontinued from 3rd day at doses of 20 and 40 mg/kg bw as the animals vomited.

Conclusion:
Based on the described findings at 20 and 40 mg/kg bw/day the NOAEL in this study was identified at 10 mg/kg bw/day.

Dog, increasing dose feeding study (1984, AL-420-004)

Guidelines: Not fully in compliance with the test method B.7 of directive 92/69/EEC. This study is a Range finder
Deviations: low number of animals, the duration of treatment is normally 28 day with the same dose
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

The objective of this study was to determine the oral maximum tolerated dose of alpha-cypermethrin in beagle dogs in a two phase range-finding study.
In phase 1, one male and one female dog were fed alpha-cypermethrin in the diet at concentrations of 200 ppm for 7 days, 400 ppm for 2 days (followed by ground diet for 5 days), and 300 ppm for 7 days. Animals were sacrificed after the third week.
In phase 2, one male and one female dog were fed diets containing 300 ppm alpha-cypermethrin for 3 or 4 consecutive days (followed by 4 or 3 days ground diet) in the first week and 250 ppm daily for 7 days in the second week. Animals were sacrificed after the second week.
No clinical manifestations in male and female dogs were seen at concentration of 200 ppm alpha-cypermethrin. At concentrations of 300 and 400 ppm in the diet, dogs of both sex showed ataxia, body tremors, subdued behaviour, head nodding, food regurgitation and inflammation of the gums and tongue. At 250 ppm alpha-cypermethrin only the female dog exhibited these symptoms.
Body weight losses were recorded in both parts of the study only in animals receiving 300 ppm alpha-cypermethrin, but recovery was evident in animals subsequently treated with 250 ppm in phase 2.
No treatment-related haematological or clinical chemistry findings, significant changes in absolute or relative organ weights, gross pathological findings, remarkable effects on urine parameters or faeces were noted that could be ascribed to treatment with alpha-cypermethrin.

Conclusion:
It was concluded that the maximum tolerated dose (MTD) of alpha-cypermethrin when administered to dogs in their diet was greater than 250 ppm but less than 300 ppm. Therefore, it was recommended that the maximum dose level in any subsequent 13 week dietary study should not exceed 300 ppm.

Additional information from the open literature presented in the DAR (1999):

Rat, gavage, 28-days, 0, 4, 8, 12mg/kg bw in soy bean oil [redacted] 1996)

16 F344 male rats received by gavage 0, 4, 8 or 12 mg/kg bw alpha-cypermethrin (99.1%) in soy bean oil during 28 days.

The main subject of this publication was a possible effect of alpha-cypermethrin on immunotoxicity. No effects on the clinical appearance, weight gain, haematological parameters and bone marrow cellularity were found. There were no effects on the relative or absolute spleen weights. The relative testes and brain weights were significantly increased in the high dose group. Histopathological examination revealed no dose-related alterations.

Conclusion:
Based on the increased relative adrenal weight at 12 mg/kg bw/d the NOAEL in this study was identified at 8 mg/kg bw/day. Alpha-cypermethrin had no effect on the immune system.

New information from the open literature presented in the AIR process:

Report: CA 5.3.1/1
Manna S. et al., 2004a
Repeated dose toxicity of alpha-Cypermethrin in rats
2004/1040514
Guidelines: none
GLP: no
(certified by none)

Short term toxicity rat gavage study; 14.5 mg/kg bw (Manna et al., 2004; Doc ID 2004/1040514)

The LD_{50} of alpha-cypermethrin (99%, Gharda Chemicals, Bombay) administered in DMSO to Wistar rats was determined by 6 dose levels ranging from 100 mg/kg bw up to 225 mg/kg bw in 25mg steps. Vehicle in each dose group was 1ml DMSO. Based on this outcome 5 rats/sex were dosed daily by gavage with 1/10 LD50 (14.5 mg/kg bw) in 1 ml DMSO for 30 days compared to a control group receiving only DMSO. After sacrifice on day 31 the activities of various hepatic enzymes and tissue residue concentrations, hematology parameters and pathological changes were investigated.
Findings: Serum AST, ALT, LDH, ALP and blood glucose were significantly elevated, RBC, PCV and HB levels were reduced. Cytochrome P450, Catalase (CAT), superoxide dismutase (SOD) and glycogen level in liver were reduced whereas Malondialdehyde (MDA) was increased. GSH levels were not affected. Residue levels were determined in brain, lungs, liver, heart, kidney and testes. Macroscopic and histological alterations were observed in lungs, liver, stomach, kidneys, testes and cerebellum.

The following tables were copied from the report:

Table 2. Effects of α-CP on certain biochemical parameters in serum and blood of rats after daily oral administration at 14.5 mg/kg for 30 days (Values are mean ± SE, n = 10)

Parameters	Control	α-CP treated
ALP activity (IU/L)	78.03 ± 2.58	161.53 ± 6.60*
AST activity (IU/L)	59.45 ± 3.52	72.00 ± 4.97*
ALT activity (IU/L)	12.00 ± 1.43	26.50 ± 1.67*
LDH activity (IU/L)	49.41 ± 2.58	64.80 ± 2.01*
TP (gm/dl)	8.12 ± .022	6.41 ± 0.17*
ALB (gm/dl)	4.53 ± 0.29	4.50 ± 0.26
GLB (gm/dl)	3.81 ± 0.21	2.16 ± 0.49*
Blood Glucose mmol/L	3.70 ± 0.48	6.22 ± 0.85*

*$p < 0.05$ in comparison with control
ALP: Alkaline Phosphatase, AST: Aspartate transaminase, ALT: Alanine transaminase; LDH: Lactate dehydrogenase, TP: Total protein; ALB: Albumin; GLB: Globulin.

Table 3. Effects of α-CP on certain biochemical parameters in liver of rats after daily oral administration at 14.5 mg/kg for 30 days (Values are mean ± SE, n = 10)

Parameters	Control	α-CP treated
CAT activity (U/mg protein)	0.39 ± 0.04	0.07 ± 0.01*
SOD (U/mg protein)	0.48 ± 0.02	0.13 ± 0.01*
MDA (nmol/mg protein)	0.24 ± 0.02	2.85 ± 0.18*
GSH (μmol/mg protein)	1.41 ± 0.16	1.30 ± 0.05
Glycogen (mg%)	7.94 ± 0.24	5.15 ± 0.34*
P450 (nmol/mg microsomal protein)	2.91 ± 0.02	2.74 ± 0.04*
b5 (nmol/ mg microsomal protein)	1.16 ± 0.07	1.28 ± 0.05

*$p < 0.05$ in comparison with control
CAT: Catalase, SOD: Superoxide dismutase, MDA: Malondialdehyde, GSH: Reduced glutathione.

Residue level of α-CP

The levels of α-CP following daily oral administration for 30 days were 0.07 ± 0.01, 0.08 ± 0.02, 0.12 ± 0.10, 0.58 ± 0.11, 1.02 ± 0.21 and 0.21 ± 0.01 ppm in liver, brain, testis, kidney, lung, and heart, respectively. Concentration of α-CP was maximum in the lungs.

Conclusion from the author: Repeated oral doses of alpha-cypermethrin to Wistar rats altered the biochemical parameters, decreased cytochrome P450 content and antioxidant status, which correlated with histopathological changes of tissues.

Comment from the applicant:
General toxicity in this study is not documented in the main study over the 30 day period.No body weights, food consumption or neurotoxicity is reported, but severe stomach and intestine hemorrhages with desquamation and necrosis of the stomach epithelium, as well as congestions in lungs, liver and kidneys are mentioned. These strong local effects in the intestinal tract are normally associated with subsequent food intake reduction. It cannot be excluded that these effects are vehicle related as DMSO can cause significant local toxic effects and data are not given to distinguish between control and treated groups. Care needs to be taken when tissue *pieces* are used for histopathology based on squeezing artefacts of tissues. In addition, testes fixation in bouins fixative leads to tubular shrinkage and condensation of chromatin which can interfere with the correct interpretation of treatment related findings. The shrinkage is also well documented in Fig.3 of the publication (see copy below left side).

Fig. 3. Photomicrograph of rat testis showing edematous fluid accumulation between the tubules (F) and vacuolation (*) within the tubule after daily oral administration of α-CP at 14.5 mg/kg for 30 days, (H & E, 100×).

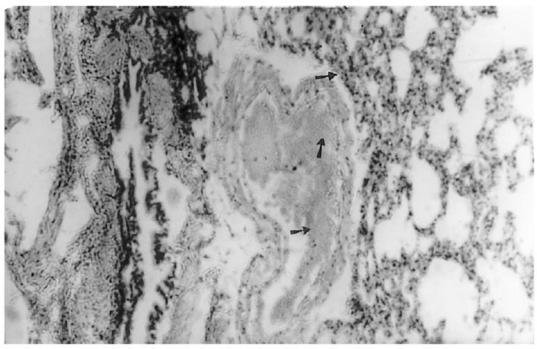

Fig. 1. Photomicrograph of rat lungs showing hemorrhages, and thickened inter-alveolar septae with infiltration of mononuclear cells (arrows) after daily oral administration of α-CP at 14.5 mg/kg for 30 days, (H & E, 450×).

This shrinkage might have been interpreted as a fluid accumulation between the tubules, which is seen only at one point (marked with F) at the border of figure 3 and would be expected to be evenly distributed between the tubules if treatment related.

Figure 1 (see copy above on the right side) in the literature shows a picture of a suboptimal preserved lung, and the arrows indicating mononuclear cell infiltration are pointing towards a blood vessel which is not appropriately recognized. Several enzyme parameters are determined which are, based on the strong intestinal effects with questionable test item-relation, not clearly attributable to alpha-cypermethrin.
In conclusion, the presented data are not convincing and the effects described might rather be attributed to administration of the vehicle or might be secondary effects to general impaired health status. Therefore, the study was not considered relevant to be taken into account in the overall conclusion

Classification of study: not further considered

Report:	CA 5.3.1/2 Prakash N. et al., 2010a Evaluation of testicular toxicity following short-term exposure to Cypermethrin in albino mice 2010/1232197
Guidelines:	none
GLP:	no (certified by none)

Mouse 28-day gavage study, 250 mg/kg bw (Prakash, 2010, Doc ID 2010/1232197)

Groups of 12 male Swiss albino mice were gavaged once daily with 250 mg/kg bw alpha-cypermethrin (1:9 in arachis oil) or vehicle alone. Six animals in each group were sacrificed on day 14 of administration of cypermethrin and remaining 12 animals in both the groups were sacrificed on day 28 of the experiment. Increased testicular wet weight but no differences in body weights were observed. Increased activities of testicular AST, ALT, and decreased epididymal ALP levels were observed. Increased cholesterol levels in the testes and reduced plasma testosterone levels were observed. The section of testis of treated group studied under Transmission electron microscope revealed changes in spermatogonic cells like rupture of cell membrane, shrinkage in the nucleus, stages of apoptosis, and condensation of chromatin decreased or absence of cytoplasmic organelles. The histological studies also revealed the pathological damage induced by the alpha-CYP on testicular tissue, which ranges from cell membrane damage of the seminiferous tubules to shrinkage in the nucleus, stages of apoptosis, condensation of chromatin, and decreased cytoplasmic organelles.

Comment from applicant:
Title, abstract and materials and methods are referring to cypermethrin dissolved in arachis oil. Otherwise alpha-cypermethrin is mentioned in the material part but without stereospecific information, so the used test substance is unclear. In the methods part it is described on the one hand that testes were frozen immediately in liquid nitrogen, but elsewhere there is the statement that testes were freshly trimmed using chilled saline solution for further investigations-so there is an unclear statement with regard to the methods used and anyway both methods are known to produce artefacts preventing evaluation of normal tissue structure. This is also documented in Fig.2 of the publication (copied below) which shows the suboptimal preservation of structures of a control seminiferous tubule.

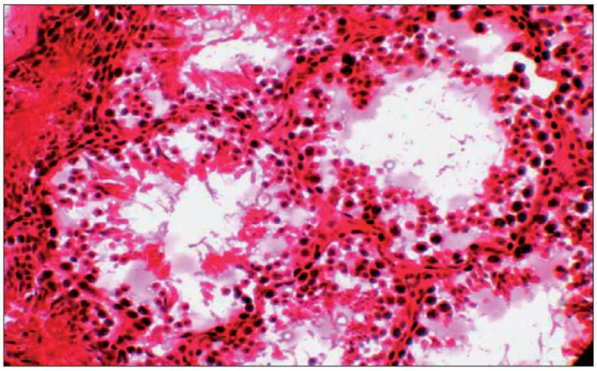

Figure 2: Transverse section of testes showing different spermatogonic cells in the semineferous tubules in control group (HandE, ×10) on day 28

A figure for comparison showing treatment-related changes is not presented. Bouins is also known to induce artefacts like tubular shrinkage and condensation of chromatin. Furthermore the paraffin sections (up to 8 µm) are too thick for microscopy. Transmission electron microscopy shown in Figure 3 and 4 of the publication presents only treatment-related slides, but no control. The described findings in Fig. 3 (not presented), like rupture of cell membrans, increased lipochrome pigment and shrinkage in the nucleus, and in Fig. 4 (not presented), like decreased cytoplasmic organelles are not seen in the images. There is no indication that the histopathological evaluation of spermatogonic cells was performed in a way which would allow to distinguish the different stages and therefore it is questionable if tubuli of the same stage were compared. Is the author aware of the spermatogenic cell turnover which includes apoptosis in some stages? The captions of the Figures 3 and 4 each do indicate 3 pictures a) to c) but there is only one picture displayed. In addition to that, there are no indices a) to c) given in these pictures. Taken everything together the inconsistency of the presentation of results makes the accuracy of the investigation rather questionable. The weight increase of testes and accessory glands combined with testosterone decrease are not a convincing finding. Furthermore, there is no information regarding general systemic toxicity. Irrespective of the used test substance (cypermethrin or alpha-cypermethrin) a high dose (250 mg/kg bw) was tested. Thus, effects in this peer-reviewed literature are likely to be secondary to impaired health status and are not relevant for risk assessment. Overall, the reliability is considered questionable and the study is therefore not further considered.

Classification of study: not further considered

CA 5.3.2 Oral 90-day study

Rat, 90-day feeding study, 0, 20, 60, 180, 540 ppm (1982, AL-425-003)

Guidelines: In compliance with the test method B of directive 87/302/EEC or OECD 408.
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

Groups of 30 male and 30 female Wistar rats received diets containing 20, 60, 180 and 540 ppm of alpha-cypermethrin (batch: OCD/7, purity: 96.5%) for up to 13 weeks. 60 male and 60 female animals served as control. After 6 weeks, one third of the animals were killed for interim haematological, clinical chemistry and gross post mortem examination.

Three males fed 540 ppm had an abnormal gait with splayed hind limbs after 14–28 days of treatment, but the histopathological examination showed no lesions in the sciatic nerves. Several instances of transient skin sores and fur loss were seen, particularly in the animals receiving 540 ppm. Other effects were generally unremarkable and females showed a lower incidence of clinical signs than males. Treatment of males and females with 540 ppm alpha-cypermethrin caused significantly decreased body weights and food consumption throughout the 13-week study period, which resulted in significantly reduced terminal body weights. Haematological and clinical chemistry findings at 540 ppm were not treatment-related, but a reflection of reduced food intake. Increased specific gravity and decreased urinary volumes at 540 ppm were attributed to decreased food and water intake.

Increased organ-to-liver weight ratios at 180 and 540 ppm were considered to represent an adaptive response of the liver to treatment with xenobiotics.
Gross and histopathological examination did not indicate any biologically significant lesions in any organ or other effects that were consistent with treatment.

No conversion from ppm to mg/kg bw/day was done in the study although food consumption and body weight were determined. In the monograph an estimation for males and females together was performed which resulted in 1, 3, 9 and 27 mg/kg bw/day for 20, 60, 180 and 540 ppm, respectively.

Conclusion:
Based on decreased body weights and clinical signs of neurotoxicity at 540 ppm, the NOAEL was determined to be 180 ppm.

New calculation of substance intake at NOAEL:
No conversion from Concentration [ppm] to Dose [mg/kg bw/day] was done in the study report although food consumption and body weight were determined. In the monograph the dose was estimated based on a conversion factor. This estimated intake at the NOAEL was replaced by calculated substance intake values (see description under study AL-420-003). Thereby the following Substance intake values at the NOAEL were calculated (see Table 5.3.2-1). The last week was not included due to food restrictions.

Table 5.3.2-1: Substance Intake values at the NOAEL taken from the DAR (1999) and newly calculated based on data in the report

NOAEL (ppm)	estimated NOAEL (mg/kg bw/day)	calculated NOAEL (mg/kg bw/day)
180	Male:9 Female: 9	Male: 13.1 Female: 15.1

Mouse, 90-day feeding study, 0, 50, 250, 1000 ppm (1994, AL-425-006)

Guideline: The study is not compulsory
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

12 CD-1 mice /sex/dose received via the diet 0, 50, 250 or 1000 ppm alpha-cypermethrin (batch: 02156, purity: 95.4%) for 13 weeks. The converted doses correspond to 6.3, 33.2 and 169.8 mg/kg bw/d for males and 7.4, 36.3 or 184.8 mg/kg bw/d for females.

At 1000 ppm 4 male mice died and 1 male mouse died from the 250 ppm dose group. These animals showed a slightly higher kidney weight. The clinical signs observed in the treated animals were thin build, ungroomed coats, hair loss (also seen at 50 ppm dose group) and encrustrations (also seen at 250 ppm) of dorsal body surface. These signs were probably due to a poor general condition.
Body weight gains were markedly lower at 1000 ppm. The overall food conversion efficiency of animals receiving 1000 ppm or 250 ppm was lower compared to the controls.

Relative kidney and liver weight were increased at 1000 ppm. An increased liver weight was also noted in females at 250 ppm. AST was increased and glucose values were decreased in males at 250 ppm and 1000 ppm. Furthermore, at the high dose an increased urinary specific gravity and a reduced urinary volume were observed.
Microscopically examination of the livers found a decreased incidence of centrilobular vacuolation/pallor and of inflammatory foci with single cell necrosis in males at 1000 ppm. These effects are considered to represent an altered hepatic metabolism which was further suggested from the increased plasma AST activity and reduced plasma glucose.

Conclusion:
Based on the effects found at 250 and 1000 ppm in this study the NOAEL was determined to be 50 ppm (6.3 mg/kg bw/day for males and 7.4 mg/kg bw/day for females).

Dog, 90-day feeding study, 0, 30, 90, 270 ppm (1984, AL-425-005)

Guidelines: In compliance with the test method B of directive 87/302/EEC or OECD 408 (1981).
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

Groups of 4 male and 4 female Beagle dogs received diets containing 0, 30 and 90 ppm of alpha-cypermethrin (batch F830047B, purity: 95.8%) while a fourth group comprised of 6 males and 6 females received 270 ppm test substance for up to 13 weeks. Dose levels were based on the results of a short-term repeated dose study in dogs ("Increasing dose feeding study in dogs").
One female animal receiving 270 ppm alpha-cypermethrin was sacrificed for human reasons in week 5. All animals receiving 270 ppm alpha-cypermethrin exhibited marked clinical signs from day 2 or 3 onwards within 3-6 hours after feeding. The signs comprised body tremors together with variable degrees of head nodding, lip licking, subduedness, ataxia or agitation. In week 3 all these dogs developed a high stepping gait and this observation, together with the instances of body tremors, head nodding, lip licking and ataxia increased gradually as the study progressed. There were no ophthalmoscopic findings.
Body weight gains and food consumption for all groups of animals were within expectation for animals of this type and age. No treatment related changes on haematology, clinical chemistry and urine parameters were observed. No treatment-related effects on absolute or relative organ weights, macroscopic examination and histopathology were seen.

Conclusion:
Based on the severity of clinical signs at 270 ppm the NOAEL was determined to be 90 ppm.

New calculation of substance intake at NOAEL:
No conversion from Concentration [ppm] to Dose [mg/kg bw/day] was done in the study report although food consumption and body weight were determined. In the monograph the dose was estimated based on a conversion factor. This estimated intake at the NOAEL is replaced by calculated substance intake values (more detailed description is given under BASF Doc ID 2013/1089655). Thereby the following Substance intake values at the NOAEL were calculated (see Table 5.3.2-2).

Table 5.3.2-2: Substance Intake values at the NOAEL taken from the DAR (1999) and newly calculated based on data in the report

Dose group	Intake estimation (mg/kg bw/day as given in the DAR (1999)	Intake (mg/kg bw/day) as calculated in BASF DocID 2013/1089655	
		male	female
90 ppm	2.25	3.5	3.8

Remark: As shown above the estimation of the intake value was lower than the calculated value. That means that the intake value given in the PPP monograph was underestimated. Since this study is pivotal and has been used for the setting of the reference value AOEL for the PPP registration it becomes absolutely necessary to base the reference value on the exact calculated value and not on mere estimation. The resulting values were already submitted in the biocide registration process for alpha-cypermethrin (Rapporteur: Belgium) and were considered acceptable.

Dog, 90-day oral administration study, 0, 1, 3, 10, and 3 mg/kg bw (1988b, [redacted])

Guidelines: Not fully in compliance with the test method B of directive 87/302/EEC or OECD 408(1981).
Deviations: Low number of animals
GLP: No
Acceptance: The study was considered acceptable in the EU registration process 1999.
5 groups of 3 Mongrel dogs per sex were fed (mixed soup) with alpha-cypermethrin (purity: 95 – 99.5%) at doses of 0, 1, 3, 10 and 3 mg/kg bw/day for 90 days consecutively. One group dosed with 3 mg/kg bw/day served as recovery group. The effect of withdrawal of alpha-cypermethrin was measured 30 days after stopping oral feeding.

No deaths occurred during the study. Some of treated animals suffered from emesis and diarrhea. Food consumption was reduced in the high dose group. The animals of the 10 mg dose group showed reduction of body weight gain. Haematological parameters were normal and BUN, serum AP, SGPT and blood sugar were comparable to the control animals. Urinanalysis was normal. Relative organ weights were normal.

Conclusion:
Based on effects found at 10 mg/kg bw/day the NOAEL was determined to be 3 mg/kg bw/day.

Remark: This study is considered to be less accurate than the 90 day dog study AL-425-005 with regard to GLP status and Deviation from Guideline. The lower NOAEL value is a result of different dose spacings but not due to higher sensitivity in this study. The 90day dog study AL-425-005 indicates that the NOAEL is slightly higher. Therefore this study is not considered for endpoint definition.

Dog, 52-week feeding study, 0, 6, 120, 240 ppm (1995, AL-427-001)

Guidelines: Not fully in compliance with the test method B of directive 87/302/EEC or OECD 452 (1981)
Deviations: 2 liver function tests, GGT and ornithine decarboxylase, were omitted. The MTD was not reached.
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

Three groups of 4 male and 4 female Beagle dogs were dosed orally via the diet, 7 days per week, for 52 consecutive weeks at concentrations of 0, 60, 120 or 240 ppm (estimated intake: 1.5, 3 and 6 mg/kg bw/day) alpha-cypermethrin (batch: 02156, purity: 95.4%).

Findings:
Daily dietary administration of alpha-cypermethrin to Beagle dogs at a concentration of 240 ppm resulted in two males showing skin reddening on the tail leading to ulceration, necrosis and amputation in one male. In addition, treatment-related abdominal skin reddening and hair loss were seen in one male receiving 240 ppm and one female receiving 120 ppm alpha-cypermethrin. It was considered possible that there were some transient effect of the test material on the skin of susceptible animals. No consistent effects that were attributable to administration of alpha-cypermethrin were observed on food consumption, body weight gain, organ weights, haematology, clinical chemistry, urinalysis, ophthalmoscopic examinations, macroscopic and microscopic examinations.

Conclusion:
Based on clinical signs of skin irritation in one female receiving 120 ppm alpha-cypermethrin the NOAEL was determined to be 60 ppm.

New calculation of substance intake at NOAEL:
No conversion from Concentration [ppm] to Dose [mg/kg bw/day] was done in the study report although food consumption and body weight were determined. In the monograph the dose was estimated based on a conversion factor. This estimated intake at the NOAEL is replaced by calculated substance intake values (the calculation is given in KCA 5.3.2/1 2013/1089655). Thereby the following Substance intake values at the NOAEL were calculated (see Table 5.3.2-3).

Table 5.3.2-3: Substance Intake values at the NOAEL taken from the DAR (1999) and newly calculated based on data in the report

Dose group	Intake estimation (mg/kg bw/day as given in the PPP monograph	Intake (mg/kg bw/day) as calculated in the statement	
		male	female
60 ppm	1.5	2.0	2.2

Remark: As shown above the estimation of the intake value was lower than the calculated value. That means that the intake value given in the PPP monograph (1999) was underestimated. Since this study is pivotal and has been used for the setting of the reference value AOEL for the PPP registration it becomes absolutely necessary to base the reference value on the exact calculated value and not on mere estimation. The resulting values were already submitted in the biocide registration process for alpha-cypermethrin (Rapporteur: Belgium) and were considered acceptable.

CA 5.3.3 Other routes

Rat, 6h/day, 5day/week, 14-day inhalation study, 0, 0.0028, 0.012, 0.029mg/l (1988c, [redacted])

Guidelines: Not fully in compliance with the test method B.9 of directive 92/69/EEC (or 84/449/EEC).
Deviations: The duration of 2 weeks is too short (28d)
GLP: No
Acceptance: The study was considered acceptable in the EU registration process 1999.

5 Wistar rats per sex and dose were exposed for 6 hours, 5 days per week for 2 weeks by nose and mouth route to an atmosphere containing 0.0028, 0.012 and 0.029 mg/L of alpha-cypermethrin (purity: 95-99.5%) produced by nebulisation. A control group was exposed to the vehicle (kerosene, 0.3 mg/L). An additional group was exposed to 0.012 mg/L and observed for 14 days after the last exposure. The particle size distribution yielded a mass median aerodynamic diameter of 3.7 µm which was within the respirable range of 0 to 7 µm.

The highest exposure concentration tested (0.029 mg/L) would be approximately equal to a dose of 3.65 mg/kg bw/day.
No mortality was observed during the study. During exposure all animals showed salivation, lacrimation and redness to nose. Food consumption and body weight gain was decreased in animals exposed to the highest dose. No treatment related findings were observed in hematology, clinical chemistry, urinanalysis, organ weights and necropsy. At the histopathological examination emphysema, perivascular and peribronchiolar lymphoid aggregation in lungs, an increased subcellularity in trachea and larynx, moderate amount of exudate containing polymorphs and desquamated cells in nose were observed in some animals exposed at different dose levels and were not dose-related. These findings were not seen in the control animals. The histopathological findings, however, not seen in the control group, point to a potential local adverse effect on the airway already produced at the lowest exposure concentration of 0.0028 mg/L.

Conclusion:
Based on the histopathological findings up to the lowest dose the NOAEL was determined to be lower than 0.0028 g/L (< 0.756 mg/kg bw/day).

Rabbit, 5days/week, 21-day dermal study, 0, 500, 1000, 2000 mg/kg bw (1988d, [redacted])

Guidelines: Not fully in compliance with the test method B.9 of directive 92/69/EEC (or 84/449/eEC),or OECD 410 (1981).
Deviations: The duration was 21 days instead of 28 days. Low number of animals
GLP: No
Acceptance: The study was considered acceptable in the EU registration process 1999.
Three rabbits per sex and dose were exposed 5 times per week with alpha-cypermethrin technical (purity: 95-99.5%) to the clipped intact dorsal skin under semi-occluded conditions for 3 weeks with a dose of 0, 500, 1000 or 2000 mg/kg bw/day. At the end of 35 days all animals were killed.

No animal died during the study. No test substance related findings were observed concerning clinical signs, skin reactions, body weight and food consumption, hematology, blood chemistry, urinanalysis and organ weights. During histopathlogical examination small tiny foci of lymphocytic infiltration in the parenchyma, occasional degenerating hepatocyte in the liver, emphysematous lung, less colloid at some places in a few follicles in thyroid were observed. These changes were found in some of the control and treated animals.

Conclusion:
Since no treatment related findings were observed up to the highest dose the NOAEL is considered to be > 2000 mg/kg bw/day.

New information from the open literature presented in the AIR process

Report: CA 5.3.3/1
Anonymous, 2009a
Adverse drug reactions /risk assessment
2009/1130982
Guidelines: none
GLP: no
(certified by none)

Alpha-cypermethrin, rabbit 28-day dermal study (Aksoy et al., 2009), Doc ID 2009/1130982

Groups of 7 adult male rabbits were treated with alpha-cypermetrhin at doses of 40, 200, and 1000 mg/kg bw. DMSO was used as a vehicle.
Findings: None of the animals died during the study. From day 18 on slight hind limb paralysis was observed in four animals of the 1000 mg/kg bw dose group. No other clinical signs were observed. There were no significant changes in body weight or food consumption during the 28-day study. There were no statistically significant changes in semen volume, concentration or motility between treatment and control groups. However, rates of abnormal spermatozoal abnormalities (head acrosome, central and caudal parts) increased significantly in a dose-dependent manner. Serum AST, ALT, GGT, ALP and cholesterol remained unchanged. However, triglyceride concentrations decreased significantly in the treated groups. There were no gross pathological changes observed in brain, liver, spleen, kidney, stomach, intestines or gonads. Histopathological changes were limited to the testes of treated animals. Many tubules had severe testicular degeneration including vacuolation between spermatogonial cells, collapsed/shrunken tubules, decreased spermatogonial cell count and intratubular giant cell formation. The severity of the testicular findings was dose-related. Blood and semen drug concentrations were dose linear.

Comment from the applicant:
The publication was only available as a short-summary of a poster presented at a conference. Thus, all findings were only presented in text form and no data were given to make an evaluation or derivation of LOAEL or NOAEL values. Material purity and supplier were not stated. Methods were not described. The histopathology findings were not described according to accepted nomenclature. The weights of the rabbits used were not in the range stated in the guideline (OECD 410) where 2-3 kg is suggested and the variation was quite high (2.36 – 3.91 kg). Based on the limited data presented the study is considered to be insufficient for assessment and was therefore not further taken into account. A regulatory study addressing this type of study was already presented in the first Annex I inclusion which did not find any substance related effects on biochemical parameters in blood despite a dosing up to 2000 mg/kg bw.

Classification of study: not considered

Remark: To address testes and sperm toxicity a 15-day gavage study in adult males has been conducted which is described in KCA 5.8.3 (see Doc ID 2014/1275120). This study with oral administration of alpha-cypermethrin to Wistar rats in corn oil did not show any effect on testes and sperm parameters

CA 5.4 Genotoxicity Testing

Studies evaluated in the draft monograph of the rapporteur member state Belgium of Sep. 1999: A sufficient data-package of in vitro genotoxicity studies in bacterial, yeast and mammalian cell systems and of in vivo genotoxicity studies conducted with alpha-cypermethrin is available. These studies were performed guideline-compliant at that time and have been evaluated by European authorities and Belgium as rapporteur member state (European Commission Peer Review Program) and were considered to be acceptable. For the convenience of the reviewer, these studies are summarized below in table form as extracted from the monograph in Table 5.4.1-1, Table 5.4.2-1 and Table 5.4.3-1 below.

Submission of not yet peer-reviewed studies in this AIR3-Dossier: No additional data on genotoxicity of alpha-cypermethrin was generated. Only additional literature data is **newly** included and discussed in chapter 5.4.1, but does not lead to a change of endpoints. The following literature data was considered relevant for discussion but was disclosed from further consideration based on the used test substance:

Table 5.4-1: *In vitro* mutagenicity study with alpha-cypermethrin (literature data)

Study type	Test System	Exposure	Result	Reference
In vitro MNT with fluorescent in situ hybridization and ethidium bromide / acridine orange fluorescence staining	*human peripheral blood lymphocyte culture* 10% EC formulation (Super Takimethrin 100 EC) Concentration: 1-30 µM	24 and 48 h without metabolic activation	Equivocal	Muranli, 2013 Doc ID 2013/1417284 Not futher considered

The summary of genotoxicity, as given in the monograph of alpha-cypermethrin, is still valid and was also supported in the biocide registration process by the respective rapporteur (Belgium).

"Alpha-cypermethrin has been tested in *in vitro* test systems using bacteria, yeast and mammalian cells to assess gene mutations, and human peripheral lymphocytes to assess chromosomal damage. Alpha-cypermethrin was not mutagenic or genotoxic in these in vitro assays. The genotoxic potential of alpha-cypermethrin was assessed *in vivo* using three test systems to evaluate potential to induce chromosomal damage or DNA damage. The results obtained show that alpha-cypermethrin was not mutagenic or genotoxic in these in vivo assays." It is therefore concluded, that alpha-cypermethrin has no mutagenic or genotoxic properties both *in vitro* and *in vivo*.

Thus, the conclusion for relevant endpoints for the current re-registration remains as follows:

Genotoxicity	
In vitro studies	No genotoxic concern
In vivo studies in somatic cells	No genotoxic concern
In vivo studies in germ cells	No genotoxic concern

CA 5.4.1 In vitro studies

A summary of the in vitro genotoxicity studies evaluated for Annex I inclusion of alpha-cypermethrin is summarized in Table 5.4.1-1 below.

Table 5.4.1-1: *In vitro* mutagenicity studies with alpha-cypermethrin

Study type	Test System	With S-9 mix	Result	Reference
In vitro Mutagenicity in bacterial cells (Ames test) OECD 471 (1983)	*Salmonella thyphimurium* (TA 98, 100, 1535, 1537, 1538); *Escherichia coli* (WP2 uvrA); Concentration up to 5000 µg/plate	No Yes	Negative Negative	1993, AL-435-005 (Cyanamid Dossier)
In vitro Mutagenicity in bacterial cells (Ames test)	*Salmonella thyphimurium* (TA 98, 100, 1535, 1537, 1538); Concentration up to 5000 µg/plate	No Yes	Negative Negative	Jones et al., 1989[1] (Gharda Dossier)
In vitro Mutagenicity in mammalian cells OECD 476 (1984)	L5178Y Mouse lymphoma cells; Concentrations up to 50 µg/mL	No Yes	Negative Negative	1993, AL-435-007 (Cyanamid Dossier)
In vitro Cytogenicity OECD 473 (1983)	Chromosome aberration in human lymphocytes; Concentrations up to 1000 µg/mL, precipitation from 625 µg/ml onwards	No Yes	Negative Negative	1993, AL-435-006 (Cyanamid Dossier)
Additional information: *In vitro* Mutagenicity in yeast	*Saccharomyces cerevisiae*; Concentrations up to 4000 µg/mL	No Yes	Negative Negative	1984, AL-435-002 (Cyanamid Dossier)

[1] This study is not BASF proprietary, but owned by Gharda, Chemical Ltd. Bombay, a further notifier for Annex I listing of alpha-cypermethrin in 1999.

Further information from the literature submitted in the AIR 3 dossier:

Report:	CA 5.4.1/1 Muranli F.D.G., 2012a Genotoxic and cytotoxic evaluation of pyrethroid insecticides Gamma-Cyhalothrin and Alpha-Cypermethrin on human blood lymphocyte culture 2013/1417284
Guidelines:	none
GLP:	no (certified by none)

Executive Summary of Literature

The authors investigated the genotoxic, cytotoxic and aneugenic potential of alpha-cypermethrin and lambda-cyhalothrin on human peripheral blood lymphocyte culture using micronucleus and fluorescence in situ hybridization (FISH) methods. For the determination of micronuclei and apoptotic effects concentrations of 1, 2, 3.75, 7.5, 15, and 30 µM were tested. For FISH analysis only 7.5 and 15 µM cypermethrin were used. Cytotoxicity was also observed using trypan blue and acridine orange/ethidium bromide fluorescence staining methods to measure the apoptotic effect. The test substance was a commercial EC formulation containing 10% active substance (for alpha-cypermethrin).

Conclusion of the author: The results of the MN assay revealed that alpha-cypermethrin showed a weak genotoxic effect on human peripheral blood lymphocyte culture. Alpha-cypermethrin has aneugenic effects shown by the FISH assay. Alpha-cypermethrin might be a spindle poison or caused damaged to centromere/kinetochore function. The results of the cell viability method indicated that alpha-cypermethrin induced cell death, at lower concentrations via apoptosis.

Conclusion of the applicant: The study shows some minor methodic deficiencies with regard to mitogenic stimuli (not over 48 h before test substance incubation as requested for human lymphocytes according to OECD guideline 487), cell proliferation index not calculated according to OECD guideline 487 (Nuclear devision index is not mentioned in OECD guideline 487), no presentation of historic control range. Besides this, the results are considered borderline and not relevant: First the viability of the lymphocytes was significantly reduced at all concentrations, and reached a cytotoxic level of 60% at 30µM and 45% at 15 µM. Significant induction of cytotoxic effects were also confirmed with the ethidium bromide/acridine orange stain at concentrations as low as 2 µM. Secondary, the MN frequency was not significantly increased at any concentration tested. FISH staining was performed to distinguish between MN induced by aneugenic or clastogenic effect. Since the increase in MN was not significant, this staining is of limited use. In addition, the validity of this staining method is of doubt based on the occurrence of only 82% C+ MN cells with the aneugenic positive control.

In conclusion, the borderline effect in this in vitro MNT is considered to be not relevant in vivo, especially based on the results of an in vivo MNT in mouse bone marrow (AL-435-008).

Furthermore, this study was performed with a 10% EC formulation of unknown composition, so that the result is not directly assignable to the active ingredient alpha-cypermethrin. Genotoxicity testing of formulations is in addition no data requirement within the EU.

Classification of study: not further considered

CA 5.4.2 In vivo studies in somatic cells

A summary of the *in vivo* genotoxicity studies evaluated for Annex I inclusion of alpha-cypermethrin is summarized in Table 5.4.2-1 below.

Table 5.4.2-1: *In vivo* mutagenicity studies with alpha-cypermethrin

Study type	Test System	With S-9 mix	Result	Reference
In vivo Cytogenicity OECD 474 (1983)	Mouse Micronucleus test (0, 1, 5, 10 mg/kg bw); Oral gavage	Not applicable	Negative	1995, AL-435-008 (Cyanamid Dossier)
In vivo Cytogenicity (B11-92/69/EEC)	Chromosome aberrations in rat bone marrow (0, 2, 4, 8 mg/kg bw); Oral gavage	Not applicable	negative	1984, AL-435-003 (Cyanamid Dossier)
In vivo Alkaline elution of rat DNA	DNA single strand breaks in rat liver/ hepatectomied rats (40 mg/kg bw); Oral gavage	Not applicable	Negative	1982, AL-435-004 (Cyanamid Dossier)

CA 5.4.3 In vivo studies in germ cells

A summary of the *in vivo* genotoxicity studies in germ cells evaluated for Annex I inclusion of alpha-cypermethrin is summarized in Table 5.4.3-1 below.

Table 5.4.3-1: In vivo mutagenicity studies with alpha-cypermethrin in germ cells

Study type	Test System	With S-9 mix	Result	Reference
In vivo Germ cell mutation	Rodent dominant lethal test Concentrations: 5, 10, 15 mg/kg bw, 5 consecutive days	Not applicable	Negative	Sengupta, 1989a, (Gharda Dossier)[1]

[1] These studies are not BASF proprietary, but owned by Gharda, Chemical Ltd. Bombay, a further notifier for Annex I listing of alpha-cypermethrin in 1999.

CA 5.5 Long-Term Toxicity and Carcinogenicity

Studies evaluated in the draft monograph of the rapporteur member state Belgium of Sep. 1999: Studies evaluated in the alpha-cypermethrin (BAS 310 I) draft monograph of rapporteur member state Belgium of September 1, 1999 consisted of: one chronic toxicity study in rats performed with cypermethrin and one carcinogenicity studies in mice performed with alpha-cypermethrin. These studies have been evaluated by European authorities and Belgium as the rapporteur member state and were considered to be acceptable. For the convenience of the reviewer, these studies are summarized below as extracted from the monograph. The results are summarized in Table 5.5-1.

Table 5.5-1: Summary of already peer-reviewed long-term toxicity/carcinogenicity studies as available in the monograph (1999)

Study	Dosages (mg/kg bw/day)	NOAEL (mg/kg bw/day)	LOAEL (mg/kg bw/day)	Main adverse effect	Reference and year
Cypermethrin 2 year chronic toxicity study in Wistar rats (diet administration of 0, 1, 10, 100,1000 ppm)	0, 0.05, 0.5, 5 and 50	5 [100 ppm]	50 [1000 ppm]	Systemic toxicity: Reduced body weight and food consumption; increased blood urea level Oncogenicity: no increase in tumor incidences	[redacted] 1978 (Dossier Cyanamid); CY-427-001 *CY-427-002* *CY-427-003* *CY-427-004*
Alpha-cypermethrin 78 week carcinogenicity study inCD1 mice (diet administration of 0, 30, 100, 300 ppm)	M: 3.0, 10.6 and 35.2 F: 3.5, 11.5 and 37.7	3 [30 ppm]	10.6 [100 ppm]	Systemic toxicity: Reduced body weight gain and food conversion efficiency; clinical signs of toxicity Oncogenicity: no evidence of carcinogenicity	[redacted] 1996 (Dossier Cyanamid) AL-428-001 AL-428-002# AL-428-003#

These studies were not listed in the former reference list but have been reported in the monograph of 1999

The results of the 2-yr chronic/carcinogenicity studies in rats with cypermethrin indicated that a maximum tolerated dose was clearly met at the high dose of 1000 ppm in males and females (corresponding to 50 mg/kg bw/day). This is demonstrated by a decrease of body weight (at nearly all weeks in males, and from weeks 1 to 75 in females) and a decrease of food consumption and an increased blood urea level. No further substance related adverse effects were observed. There was no evidence of a treatment-related increase in neoplasms. Due to the composition and toxicological similarities of cypermethrin and alpha-cypermethrin, it is unlikely that there would be significant differences between these two compounds with regard to carcinogenicity. These findings are supported by the absence of genotoxic activity for alpha-cypermethrin.

A carcinogenicity study in mice was conducted up to 300 ppm with alpha-cypermethrin. The maximum tolerated dose was found to be at 100 ppm as evidenced by body weight gain depression, reduced food conversion efficiency and clinical signs of toxicity. No further substance related effects were observed in this study. There was no evidence of a treatment-related increase in neoplasms.

Based on the available data, the following endpoint was determined during the last Annex I listing of alpha-cypermethrin concerning:

Long term toxicity and carcinogenicity

Target/critical effect	Clinical signs of toxicity, body weight reduction
Lowest relevant NOAEL / NOEL	78-wks, mouse: 3 mg/kg bw/day
Carcinogenicity	No evidence of carcinogenicity

Supporting evidence from peer-reviewed studies from other DARs: Furthermore, one chronic toxicity study in rats performed with cypermethrin is available which has been evaluated in the zeta-cypermethrin draft monograph of November 2006 by the rapporteur member state Belgium. In addition beta-cypermethrin was investigated in a chronic toxicity study in wistar rats and the study has been evaluated in the beta-cypermethrin DAR by the rapporteur member state United Kingdom (2013).

Table 5.5-2: Summary of other peer reviewed long-term toxicity/carcinogenicity studies in rats published in related DARs

Study	Dosages (mg/kg bw/day)	NOAEL (mg/kg bw/day)	LOAEL (mg/kg bw/day)	Main adverse effect	Reference and year
Cypermethrin 2 year chronic toxicity study in Wistar rats (diet administration 0, 20, 150, 1500 ppm)	0, 1, 7.5 and 75	7.5 [150 ppm]	75 [1500 ppm]	Systemic toxicity: Reduced body weight gain, food consumption and efficient food utilization; clinical signs of toxicity Oncogenicity: no increase in tumor incidences	From the DAR of zeta- and cypermethrin: [redacted] 1982;
Beta-cypermethrin 2 year chronic toxicity study in Wistar rats (diet administration 0, 50, 250, 1000/500 ppm	0, 2.3/3.0, 12.3/16.5, 25/31.8 mg/kg bw males / females	12.3 [250 ppm]	25 [500 ppm]	Systemic toxicity: Clinical signs of toxicity, reduced body weight gain, food consumption and liver histopathology Oncogenicity: no increase in tumor incidences	From the DAR of beta-cypermethrin; (2009)

In these studies with cypermethrin and beta-cypermethrin in Wistar rats (summarized in the respective DARs) findings were broadly similar to those described in the original alpha-cypermethrin DAR for chronic toxicity studies in Wistar rats, with no evidence of carcinogenic potential and the primary findings being related to food consumption and body weight.

Studies submitted in this AIR 3 dossier:
There are no new studies available with alpha-cypermethrin that affects the overall evaluation for long-term toxicity and carcinogenicity. Thus, the conclusion for relevant endpoints for the current re-registration remains as follows:

Long term toxicity and carcinogenicity

Target/critical effect	Clinical signs of toxicity, body weight reduction **No classification required**
Lowest relevant NOAEL / NOEL	78-week, mouse: 30 ppm (3 mg/kg bw/day)
Carcinogenicity	No evidence of carcinogenicity **No classification required**

For convenience of the reviewer brief summaries of the studies listed in the DAR of the draft monograph of alpha-cypermethrin are provided below.

Cypermethrin, Rat 2-year oral study (1978, CY-427-001, CY-427-002, CY-427-003, CY-427-004)

Guidelines: Not fully in compliance with the test method B of directive 87/302/EEC.
Deviations: Low number of rats, blood albumin, glucose, GGT, and ornithine decarboxylase were not measured. Urinalysis was not performed.
GLP: No
Acceptance: The study was considered acceptable in the EU registration process 1999.

The chronic toxicity and carcinogenicity of cypermethrin (WL 43467, batch 30, purity: 98%) was tested in 24 Wistar rats per sex fed the test substance at dietary concentrations of 1, 10, 100, and 1000 ppm. A control group of 48 animals per sex received untreated diet. Groups of rats were scheduled for necropsy after 6 months (6 per sex treated, 12 per sex control), 12 months (6 per sex treated, 12 per sex control), 18 months (12 per sex treated, 24 per sex control) and 2 years (24 per sex treated, 48 per sex control) of treatment.

Male and female rats exposed to 1000 ppm cypermethrin had reduced body weights throughout the study. The trend was consistent but not always statistically significant. During the first 13 weeks, small, sometimes statistically significant, reductions in food consumption were seen in the 1000 ppm group males and females. Thereafter, only minor fluctuations in food intake were observed.
No significant differences in survival were seen between treatment and control groups. Clinical chemistry revealed induction of Cyp 2B1 at high dose. There were no treatment-related effects on haematology and organ weights. Macroscopic and histopathological examination did not indicate any biologically significant lesions in any organ or other effects that were considered to be related to treatment. Sciatic nerves showed age dependent nerve fiber exhibiting the changes of Wallerian degeneration, but the incidence of this was not dose related.
A wide spectrum of tumors and degenerative and other lesions were seen at post-mortem and microscopically. None appeared to be compound-related.
Conclusion: Based on the described findings for both sexes the NOAEL (chronic effects) was determined to be 100 ppm corresponding to 5 mg/kg bw/day. Since no treatment related tumors were observed a NOAEL (for oncogenic effects) was determined to be 1000 ppm corresponding to 50 mg/kg bw/day for both sexes.

Alpha-cypermethrin, mouse 78-week oral study [redacted] 1996)

Guidelines: Fully in compliance with the test method B of Directive 87/302/EEC.
Deviations: No
GLP: Yes
Acceptance: The study was considered acceptable in the EU registration process 1999.

Groups of 72 male and 72 female CD-1 mice received diets containing 0, 30, 100 and 300 ppm of alpha-cypermethrin, equivalent to 3/3.5, 10.6/11.5 and 35.2/37.7 mg/kg bw for males /females, respectively. 20 males and 20 females of each group were sacrificed for interim examination, after 52 weeks, the remainders were sacrificed after 78 weeks of treatment.

Administration of alpha-cypermethrin (batch: 02156, purity: 95.4%; cis1/cis2 isomer ration: 1:99) to CD-1 mice for 78 weeks was associated with a number of non-specific effects.
Treatment of animals with 300 ppm alpha-cypermethrin resulted in poor growth performance and changes in appearance. In males, this was evident by a higher incidence of thin build during the in-life phase. Signs of reaction to treatment were, generally, confined to males receiving 300 ppm and included ungroomed coats, hair loss and surface encrustations on the skin and were probably related to the irritant properties of the test material. Other signs of reaction included occasional hunched posture in males and over-activity in females receiving 300 ppm.
Overall weight gains of males and females in the 300 ppm group were 26 and 24% lower than those of the controls and were associated with a reduced efficiency of food conversion. This is considered indicative of a non-specific toxicity rather than an influence of food intake. A similar, less marked effect on weight gain and food conversion efficiency was noted for males receiving 100 ppm.
No treatment-related effects on hematology or organ weight changes were seen, and macroscopic and histopathological examinations revealed no changes attributable to treatment with the test substance. There was no evidence that alpha-cypermethrin had any oncogenic potential at concentrations up to 300 ppm.
Conclusion: Based on the poor growth performance and changes in appearance the NOAEL was determined to be 30 ppm corresponding to 3.0 mg/kg bw/day for males and 3.5 mg/kg bw/day for female mice. Alpha-cypermethrin showed no oncogenic potential in mice up to the highest dose tested.

Alpha-cypermethrin, mouse 18-month oral study (disregarded; [redacted] 1990; Dosssier Gharda)

Guidelines: Not fully in compliance with test method B of Directive 87/302/EEC.
Deviations: Number of animals not given. Blood sampling not performed at 12 months. Animals were not weighed 1 time/week and food consumption is not measured 1 time/week. The dose is given in ppm in food and in some tables expressed in mg/kg of ?. Incomplete histopathology and individual data are missing.
GLP: No data
Acceptance: The study was not used for final evaluation in the EU registration process 1999.

Albino mice (Swiss strain) were expose to alpha-cypermethrin (99%) in diet, 6 day/week during 18 months at 6.5, 13 or 65 ppm for males and at 7.8, 15.6 or 78 ppm for females. This study has many qualitative deficits and is quite difficult to interpret. The deficits are: the experimental protocol is not clearly defined; the number of animals used is not given; blood sampling is not performed at 12 months; the animals were not weighed one time/week and food consumption is not measured one time/week; the dose is given in ppm in food and in some tables expressed as mg/kg ?; incomplete histopathology; individual data are missing. Due to these deficits the study was not used for the final evaluation.
Nevertheless, possible treatment related findings were observed: hepatocytic cytoplasm vacuolization with loss of cytoplasm in the high dose, scarring of renal capsule with varying degree of nephritis in the medium and high doses, fatty degeneration and tubular swelling in the high dose animals; dilatation of the spleen with distortions of the white and red pulp in the medium and high dose; spermatic tubes more or less choked with Sertoli cells, and degeneration of Leydig cells in the high dose with only temporary arrest of spermatogenesis in some animals.

CA 5.6 Reproductive Toxicity

Studies evaluated in the draft monograph of the rapporteur member state Belgium of Sep. 1999: The alpha-cypermethrin studies - evaluated in the draft monograph of the rapporteur member state Belgium of September 1999 - consisted of a three-generation study in rats and developmental toxicity studies in rats and rabbits. Furthermore, a three-generation study in rats is available with cypermethrin. These studies have been evaluated by European authorities and Belgium as Rapporteur member state and were considered to be acceptable. For the convenience of the reviewer, these are summarized below as extracted from the monograph and discussed during the ECCO Peer review meeting (2001) - Full Report on alpha-cypermethrin (DocID AL-901-031). For a better overview the endpoints parental toxicity, reproductive toxicity and developmental toxicity were addressed separately.

Table 5.6-1: Summary of already peer-reviewed reproduction toxicity studies as available in the monograph (1999) and supplemented according to discussions during the ECCO Peer review meeting (2001)

Study	Dosages (mg/kg bw/day)	NOAEL (mg/kg bw/day)	LOAEL (mg/kg bw/day)	Main adverse effect	Reference and year
Alpha-cypermethrin 3-Generation study, oral, Young Charles Foster rats (gavage, vehicle unknown)	M: 0, 2.5, 10 and 25 F: 0, 5, 10 and 20	Parental toxicity: 20 Reproductive toxicity: 20	Parental toxicity: > 20 Reproductive toxicity: > 20	Parental toxicity: no maternal toxicity Reproductive toxicity: no effects	[redacted] 1989b (Gharda Dossier)
Cypermethrin 3-Generation, oral, feed Wistar rats (diet concentrations: 0, 10, 100 and 500 ppm)	0, 1, 10 and 50 (nominal) Calculated: 0, 1, 9.0/10.8, 44.8/51.4	Parental toxicity: 9 [100 ppm] Reproductive toxicity: 9 [100 ppm] Developmental toxicity: 9 [100 ppm]	Parental toxicity: 44.8 [500 ppm] Reproductive toxicity: 44.8 [500 ppm] Developmental toxicity: 44.8 [500 ppm]	Parental toxicity: reduced body weight and food consumption; Reproductive toxicity: reduced litter size No adverse effects on fertility. Developmental toxicity: reduced pup body weight day 21 (F1B and F3B)	[redacted] 978 CY-430-001 (Cyanamid Dossier) Addendum/ Corrigendum CY-430-002 CY-430-003 CY-430-004 CY-430-005
Alpha-cypermethrin Developmental toxicity, gavage (days 6-15), Sprague-Dawley rat	0, 3, 9, 18/15 and 15	Maternal toxicity: 9 Developmental toxicity: 9	Maternal toxicity: 15 Developmental toxicity: 15	Maternal toxicity: Clinical signs (unsteady gait, hind limb splay), reduced body weight and food consumption Developmental toxicity: Reduced fetal weight	[redacted] 1994a AL-432-002 [redacted] 1994a AL-432-001 (Cyanamid Dossier)

Table 5.6-1: Summary of already peer-reviewed reproduction toxicity studies as available in the monograph (1999) and supplemented according to discussions during the ECCO Peer review meeting (2001)

Study	Dosages (mg/kg bw/day)	NOAEL (mg/kg bw/day)	LOAEL (mg/kg bw/day)	Main adverse effect	Reference and year
Alpha-cypermethrin Developmental toxicity, gavage (days 7-19), New Zealand White rabbits	0, 3, 15 and 30	Maternal toxicity: 15 Developmental toxicity: 30	Maternal toxicity: 30 Developmental toxicity: > 30	Maternal toxicity: Reduced body weight and food consumption Developmental toxicity: No evidence of developmental toxicity.	[redacted] 1994b AL-432-004 [redacted] 1994b AL-432-003 (Cyanamid Dossier)

The summary of reproductive toxicity studies as given in the monograph and amended in accordance to the discussions at the ECCO 102 meeting is as follows: "*There is no good study currently available to assess the multigeneration reproductive toxicity potential of alpha-cypermethrin in the rat. Data from a badly documented study did not show any toxic effect on reproduction or development. This is compatible with the results of an acceptable study with cypermethrin. Cypermethrin did not cause any significant effects on fertility or reproductive performance of rats.*" The delayed pregnancies mentioned in the DAR were stated as being a misinterpretation of the rapporteur, therefore it is concluded that there was in addition no evidence of significant pre- or post-natal effects.

"*In the developmental toxicity studies in rat and rabbit with alpha-cypermethrin, there was no evidence of adverse effects on embryonic development. There was no maternal or developmental toxicity associated with oral administration of alpha-cypermethrin.*

In the dossier on cypermethrin, the RMS reported data from the open literature in which it was suggested that cypermethrin might induce a delayed maturation of cerebral cortex and caused a long-lasting impairment of dopamine receptors. The neurobehavioral findings and biochemical changes published in the open literature are very limited in scope, are not reproduced and no firm conclusions can be drawn. As cypermethrin has been tested in a multigenerational reproduction study in rats, without any indication of persistent effects in the offspring, which were also exposed to the substance neonatally, it is suggested that receptor binding changes are not predictive or causally related to the behavioral changes. Moreover, the vulnerable phase for humans during the brain growth spurt is prenatal and not post-natal as in rodents. Therefore, exposure of the human fetus will be limited by maternal pharmacokinetics as well as maternal toxicity."

Based on the available data, the following endpoints were determined during the last Annex I listing of alpha-cypermethrin.

Reproductive toxicity

Reproduction target / critical effect	No reproductive toxicity
Lowest relevant reproductive NOAEL / NOEL	>20 mg/kg bw/day
Developmental target / critical effect	Reduced fetal weight at maternal toxic doses
Lowest relevant developmental NOAEL / NOEL	Rat: 9 mg/kg bw/day

Supporting evidence from peer-reviewed studies not belonging to BASF from other DARs: According to the DARs of zeta-cypermethrin and beta-cypermethrin, prepared by Belgium (2008) and UK (2013), neither cypermethrin, nor zeta-cypermethrin or beta-cypermethrin are considered to show evidence for reproduction toxicity from scientifically acceptable studies. For the convenience of the reviewer, the reproduction toxicity studies of zeta-cypermethrin, cypermethrin, and beta-cypermethrin are summarized in the Table below as extracted from the DARs.

Table 5.6-2: Summary of already peer-reviewed confirmatory data on cypermethrin, zeta-cypermethrin and beta-cypermethrin (as presented in the DARs)

Study	Dosages (mg/kg bw/day)	NOAEL (mg/kg bw/day)	LOAEL (mg/kg bw/day)	Main adverse effect	Reference and year
Cypermethrin 3-Generation, oral, feed Wistar rats (diet concentrations: 0, 50, 150 and 750/1000 ppm)	**Conversion factor of 1/10*:** 0, 5, 15, 75	Parental toxicity: 5 [50 ppm] Reproductive toxicity: 75 [750 ppm] Developmental toxicity: 15 [150 ppm]	Parental toxicity: 15 [150 ppm] Reproductive toxicity: - Developmental toxicity: 75 [750 ppm]	Parental toxicity: decreased parental bw gain, food consumption and food utilization Reproductive toxicity: no effects Developmental toxicity: decreased litter body weight gain in F1B, F2B and F3B	[redacted] 1982 (taken from DAR of zeta-cypermethrina nd adapted to 1/10 conversion factor)
Zeta-cypermethrin 2-Generation study, oral, feed, Sprague-Dawley rats (diet concentrations: 0, 7.5, 25, 100, 375, 750 ppm (exceeded MTD)	0.4, 1.5, 5.9, 22 and 43	Parental toxicity: 5.9 [100 ppm] Reproductive toxicity: 22-43 [375-750 ppm] Developmental toxicity: 5.9 [100 ppm]	Parental toxicity: 22 [375 ppm] Reproductive toxicity: - Developmental toxicity: 22 [375 ppm]	Parental toxicity: Clinical signs of neurotoxicity, reduced body weight, body weight gain, food consumption Reproductive toxicity: - Developmental toxicity: reduced pup weight during lactation; pup mortality at 750 ppm probably related to less maternal care	[redacted] 1991 (taken from DAR of zeta-cypermethrin)
Beta-cypermethrin 2-generation study, oral, gavage, Sprague-Dawley rats in 1% CMC	**0, 3, 12, 30/40**	Parental toxicity: 30 Reproductive toxicity: 30 Developmental toxicity: 30	Parental toxicity: >30 Reproductive toxicity: >30 Developmental toxicity: >30	No treatment related effects on reproductive performance, parents or offspring up to the highest dose tested.	2005 (taken from DAR of beta-cypermethrin)

* conversion factor of 1/20 is considered to be not adequate based on the comparison with the study performed by [redacted] 1978 in the same rat strain at the same time

The study performed with cypermethrin was summarized in the DAR of Zeta-cypermethrin in the following passage:

*Parental toxicity was evidenced by the reduced bw gain, food consumption/utilization seen at 150 ppm (*15 mg/kg bw*). Signs of neurotoxicity were reported at the high dose of 1000 ppm (*100 mg/kg bw*). No reproductive toxicity was observed. Body weight gain was reduced in pups of both sexes in some litters from the 750 ppm group where clear maternal toxicity was observed. (taken from the DAR of Zeta-cypermethrin except for the substance intake values).*

The study performed with zeta-cypermethrin was summarized in the DAR of Zeta-cypermethrin in the following passage:
In a 2-generation study, zeta-cypermethrin was investigated at doses ranging from 7.5 to 750 ppm [in Sprague-Dawley rats]. The NOAEL reproduction at 750 ppm (43 mg/kg bw/d)for the P1 generation and 375 ppm (22 mg/kg bw/d) for the F1 generation is proposed because mortality prevented evaluation of the reproductive performance of the 750 ppm group second generation. Decreased body weights, body weight gains, and clinical signs of toxicity were seen at 375 ppm (22 mg/kg bw/d). Reduced pup body weights in both generations during the lactation periods and pup mortality were reported at maternal toxic dose of 375 ppm.

The study performed with beta-cypermethrin was summarized in the DAR of beta-cypermethrin in the following passage:
"In the two-generation-study, using gavage dosing, there were no adverse effects on reproductive performance or on general toxicity in parents up to the highest dose tested of 30 mg/kg bw/day."
This study also included oestrus cycle and sperm analysis data at the highest dose of the F0 and F1 generation and did not find adverse effects.

Studies submitted in this AIR 3 dossier (not yet peer-reviewed):
There are no new studies available with alpha-cypermethrin that could affect the overall evaluation for reproductive toxicity. Thus, the conclusion for relevant endpoints for the current re-registration remains as follows:

Reproductive toxicity (SANCO/11802 data point 5.6)

Reproduction target / critical effect	No reproductive toxicity effects No classification required
Lowest relevant reproductive NOAEL / NOEL	> 20 mg/kg bw/day
Developmental target / critical effect	Reduced fetal weight at maternal toxic doses No classification required
Lowest relevant developmental NOAEL / NOEL	Rat: 9 mg/kg bw/d

No classification for reproductive or developmental toxicity is considered necessary.

CA 5.6.1 Generational studies

Alpha-cypermethrin - Three Generation reproduction study in rats ([redacted] 1989b)

Guidelines: Not fully in compliance with the test method B of directive 87/302/EEC.
Deviations: Daily dosing of males should begin when rats are about 5 to 9 weeks old for 10 weeks prior to the mating period. Administration route is not defined. During premating and mating periods, after parturition and during lactation food consumption was not measured and only female body weights were reported.
GLP: No
Acceptance: The study was considered acceptable in the EU registration process 1999

Eight males and sixteen female Young Charles Foster rats were exposed to alpha-cypermethrin at doses of 0, 2.5 (♂) – 5 (♀), 10 and 25 (♂) – 20 (♀) mg/kg bw/day. Dosing of the test compound started at about 100 days of age. Male rats were treated for at least 60 days (= 8.5 weeks) and females for 15 days prior mating, treatment then continued through mating, gestation and lactation. At weaning the administration of the substance is continued to F1 offspring during their growth into adulthood, mating and production of F2 generation. The administration is continued as for F1 generation till F3 generation is weaned and attains 100 days age. The conduct of the study was consistent to OECD 416 (2001) in all important aspects with the exception that the test procedure was extended to three generations and the daily dosing of males should begin when rats are about 5 to 9 weeks old for 10 weeks prior to the mating period. Administration route and vehicle is not defined. During pre-mating and mating periods, after parturition and during lactation food consumption was not measured and only female body weights were reported.
Findings:
Body weight was normal in pregnant females. Parturition was normal. The various reproductive indices calculated for the test and control animals do not indicate any adverse effect on reproduction and lactation response. There is no significant difference in the total number of pups born to control and treated P0, P1 and P2 mothers. The proportion of live pups at birth and the proportion surviving to 3/4 days post-partum in various treatment groups are similar to the controls and highest and intermediate groups. The number of pregnancies observed in the P0, P1, and P2 generations are comparable in the controls and highest and intermediate groups. The comparative litter size of F1A, F2A and F3A dams is similar in all the treatment and control groups. (In the discussions during the ECCO Meetings the RMS stated that the delayed pregnancy finding was a mis-interpretation. See DocID AL-901-031, page 100 of 222, Point No 4. This is also documented in the List of endpoints in the Review Report.) No parameter of developmental toxicity is discussed in this summary.

Conclusion
Alpha-cypermethrin was not reported to have adverse effects. Therefore the NOAEL for systemic toxicity and reproductive toxicity is considered to be 20 mg/kg bw/day.

Cypermethrin - Three Generation reproduction study in rats ([redacted] 1978) CY-430-001-CY-430-005)

Guidelines: Not fully in compliance with the test method B of directive 92/69/EEC.
Deviations: Males and females were exposed for 5 weeks: normally, in male rats dosing is continued for 10 weeks prior to the mating period. Females must be dosed throughout the 3 week mating period, pregnancy and up to the weaning of the F1 offsprings.
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.
Remark: The terminology used to designate the parental and offspring groups of animals in the study report is different from the currently accepted designators. The report uses "F0, F1,and F2" to describe the original parental and first, second and third generation offspring generations with appropriate subscripts for the first or second litter in that generation. Current terminology employs the descriptors "P0, F1 and F2" to describe the parental generations and F1, F2 and F3, with the added subscript "a" or "b" to describe the offspring. The terminology used here follows the latter scheme and updates that used in the report.

Groups of approx. 30 Wistar rats per sex in the parental generation (and less in other generations due to mating not resulting in pregnancy, single sex litters, or low survival up to weaning, see Table below) received cypermethrin at dietary concentrations of 0, 10, 100 or 500 ppm throughout the entire experimental period up to weaning of F3 litters (pre-mating, mating, gestation and rearing).

		Number of animals			
		Control	10 ppm	100 ppm	500 ppm
Parents P0	Male	30	30	30	30
	Female	30	30	30	30
F1	Male	28	25	28	25
	Female	28	25	28	25
F2	Male	18	20	19	19
	Female	18	20	19	19

Two litters were produced from each parental generation, one was killed at weaning (PND 21) whereas the second litters were randomly selected for mating. The conduct of the study was consistent to OECD 416 (1983) in all important aspects, with the exception that the test procedure was extended to three generations, that males of the P-generation were dosed for less than 10 weeks prior to mating, and that food consumption and body weight were only recorded during the pre-mating period.

Findings in the adults:
General health and behaviour of treated animals were comparable to control animals. P0, F1 and F2 body weights were lower at 500 ppm but not at 10 and 100 ppm. Reduced food intake for the P0 females at 500 ppm (week 3 to 7), sporadically for males at 10, 100 and 500 ppm, was lower than controls and was believed to be related to non-palatability of the diet. Lower food intakes at weeks 6 and 7 were in females were associated with adverse body weight effects and were considered to be related to exposure.
Fertility, gestation, viability and lactation indices were similar for treated and control animal within each generation.

Table 5.6.1-1: Three generation body weight and food consumption data

Dose	0 ppm		10 ppm		100 ppm		500 ppm	
Adult rat P0	♂	♀	♂	♀	♂	♀	♂	♀
Food intake			↓wk 3,4,5 (4%)		↓ wk 3,4 (4%)		↓ wk 3&7 (7%)	↓ wk 3-7 (6-7%)
Body weight							↓	↓ (4-5%)
Adult rat F1, F2								
Food intake			↓ wk 3 (F1: 8%)					↓ wk 3-7 (F1: 6-8%) ↓ wk5&7 (F2: 11-16%)
Body weight							↓ (F1: 4-5%)	↓ (F1: 4-7%) ↓ (F2: 5-6%)

Findings in the litters:
At 500 ppm: Lower litter sizes and weights and lower pup weights, mainly for the F1A. Mean pup weights were significantly lower compared with controls for F1B females pups and for pups of both sexes for F3B pups.
At 100 ppm and at 10 ppm, the number of female pups per litter for F1B litters was higher. No treatment-related adverse effects on litter weights were observed. Mean pup weight was reduced at in F3B at PND 21 male offspring. Using the litter as experimental unit, no statistically significant differences were reported at 10 and 100 ppm.
At 10 ppm, significantly lower litter size for F1A pups and F2B pups were not considered to be toxicologically relevant as similar changes were not observed at 100 ppm. Significantly increased mean pup weights recorded for F1A litters reflected the lower litter sizes at day 7,14 and 21.

Table 5.6.1-2: Three generation reproductive toxicity in the rat – litter data.

Endpoint/dose	0 ppm	10 ppm	100 ppm	500 ppm
Litter survival:				↓ F1A (PND 0, 7, 21)
Litter size:				
F1A				↓ PND 7-21
F1B, F2A, F2B, F3A, F3B	No effect			
Number of female pups / litter				
F1A				↓ PND 1&21
F1B		↑ PND 1&21	↑ PND 1&21	
F2A, F2B, F3A, F3B	No effect			
Mean litter weights:				
F1A				↓ PND 7-21
F1B		↑ PND 7		
F2A, F2B, F3A, F3B	No effect			
Mean pup weight:				
F1A		↑ PND 14 & 21		
F1B				♀: ↓ 10 % PND 21
F2A, F2B, F3A	No effect			
F3B		♂: ↓ 10 % PND 21	♂: ↓ 11 % PND 21	♂: ↓ 9% PND 21 ♀: ↓ 6 % PND 21

Upon necropsy, no compound-related gross or microscopic pathological findings were observed. Beside the tables described in the monograph, more detailed tables are found in full report on alpha-cypermethrin from the ECCO peer review program.
Remark from BASF: The test compound intake has been calculated based on the weekly mean intake values

		Test compound intake (mg/kg bw/d)*	
		100 ppm	500 ppm
Parents P0	Male	9.9	50.3
	Female	11.2	56.4
F1	Male	9.6	48.9
	Female	11.1	57.2
F2	Male	9.0	44.8
	Female	10.8	51.4

* Calculated with weekly mean values (week 2-7);
NOAEL/LOAEL=NOAEC/LOAEC x daily food consumption / body weight

Based on these calculations it seems to be adequate to take a factor of 1/10 for Wistar rats in this typ of study when converting diet concentration in dose. This was already done in the previous monograph and is in compliance with the EFSA Guidance on selected default values (EFSA Journal 2012; 10(3): 2579). This information is of importance when the substance intake in the cypermethrin study of [redacted] 1982 is estimated. In this study a default value of 1/20 was considered but seems to be not adequate with regard to this study in the same strain of rats.

Conclusion
Based on the described maternal toxicity and reproductive effects at 500 ppm (corresponds to approx. 50 mg/kg bw (lowest value 44.8 mg/kg bw/day) the NOAEL for maternal toxicity and reproductive effects was considered to be 100 ppm (corresponding to approx. 10 mg/kg bw (lowest value 9 mg/kg bw/day).

Additional data taken from the open literature:

Report:	CA 5.6.1/1 Anonymous, 2006a Draft Assessment Report (DAR) Zeta-Cypermethrin - Volume 1 to volume 3 - Initial risk assessment provided by the RMS Belgium of the third stage (part A) of the review programme referred to in article 8(2) of council directive 91/414/EEC 2006/7013990
Guidelines:	none
GLP:	no (certified by none)

Remark: [redacted] 1982 ***) (copied from Monograph of zeta-cypermethrin)***
Cypermethrin - Three Generation reproduction study in rats [redacted] 1982)

Remark from BASF:
The conversion of concentration in feed into daily dose in rats was estimated in the study of [redacted] 1982 based on a factor of 1/20. As this study was performed in the same rat strain than that used in the Cypermethrin study performed by [redacted] 1978 (see study before) it is considered more adequate to use a factor of 1/10. This is also in accordance to the EFSA Guidance on default values, where only chronic toxicity studies are converted with a 1/20 factor, whereas subchronic studies are converted with a 1/10 factor. Taking this into account the NOAEL in the cypermethrin study performed by [redacted] 1978 is considered adequate as it is below the LOAEL generated in [redacted] under consideration of a conversion factor of 1/10. Furthermore the study comprises some discrepancies that render the study less valid. On the one hand there was a light cycling problem which is important for the correct mating and fertility parameters and on the other hand 1/3 of the control animals are mentioned to be sub-/or infertile, which indicate further difficulties in the study that might have compromised the integrity of the study or affect the scientific interpretation of the results.

Guidelines:	*Study protocol is not fully conform to EEC 87/302 Annex V B.35 or OECD guideline 416 (1983)*
Deviations:	*Highest dose was reduced at the end of premating period; weanling was postponed. Females, which were not gravid after 10 days, were placed by another male. Histopathology of vagina and coagulating gland was not performed.*
GLP:	*No (not mandatory at that time)*
Acceptance:	*The study was considered acceptable in the EU registration process 2008.*

Material and methods: 15 males and 30 females Wistar rats received in their diet cypermethrin (batch n° P19, P24, P26; purity 91.5, 93.1, 90.6 %) at 0, 50, 150, 750 ppm throughout the entire experimental period up to weaning of F3 litters. The high dose level was 1000 ppm for the first 12 weeks of the F0 parental rats but was reduced to 750 ppm due to neurological disturbance seen in the early part of the period. Stability and homogeneity in food was evaluated and satisfying and food was prepared every one to two weeks.
Findings: The high dose level was 1000 ppm for the first 12 weeks of the P0 parental rats but was reduced to 750 ppm due to neurological disturbance seen in the early part of the period.
Two problems were encountered in the conduct of the study. Firstly the automatic time switch on the lighting in the animal room was faulty for up to one month leaving rats in almost light on each day during mating and gestation to produce F1A litter. During continuous light the diurnal rhythms would have been affected leading to failure of the normal estrus cycle. This was the most probable cause of the overall low fertility during production of the F1A litter.
Secondly, there was difficulty in obtaining the required number of F1B and F2B litters; it was necessary to arrange three pairings before this was achieved. No reason for this difficulty was identified and it was unexpected since the F1 parents had readily produced the F2A litters a few weeks earlier with no difficulties and since the probable reason for low fertility of P0 females producing the F1A litter had been identified and rectified.
The above problems did not compromise the integrity of the study or affect the scientific interpretation of the results.
Clinical signs: During the first three weeks of feeding of the F0 parents at 1000 ppm, neurological disturbance was seen in most rats. The clinical signs were typical of those associated with pyrethroid toxicity. For this reason, the dietary concentration of cypermethrin administered in the top dose group was reduced from 1000 to 750 ppm after feeding to the F0 parents for 12 weeks. In addition separation of pups from mothers took place at 28 instead of 21 days post partum and pups were then kept in litters for a further seven days before selection of the next generation of parents. These alterations in experimental design ensured that there was no difficulty with undue toxicity in pups of subsequent generations.
No treatment related changes were detected in the central or peripheral nervous systems of any animal examined on the study in spite of clinical signs of neurological disturbance at 1000 ppm. This was also true for the F0 male, which died after showing signs of neurological disturbance. A dietary concentration of 750 ppm produced a definite toxic effect.
Body weight gain: a reduction in parental body weight gain throughout the study was reported, generally accompanied by reduced food consumption and less efficient food utilization. The only consistent evidence of a toxic effect in rats fed 150 ppm was a reduction in body weight gain in F2 parents. There was no evidence of any effects at a dietary concentration of 50 ppm.
In pregnant females the only effects seen was reduction in body weight gain in F1 and F2 females producing their respective B litters, at 750 ppm. Similarly the only effect in offspring was a reduction in the body weight gain of B litter offspring at 750 ppm.
Reproductive parameters were not affected.
In all the offsprings of each generation there were no clinical or behavioral abnormalities, which could be related to treatment.
Soft tissue examination of pups revealed no abnormalities, which could be compound-related.

Conclusion*:*
NOAEL reproductive toxicity >750 ppm; NOAEL systemic toxicity = 50 ppm based on the decreased parental body weight gain, food consumption and food utilization seen at 150 ppm; NOAEL developmental toxicity = 150 ppm based on decreased litter body weight gain seen at maternal toxic doses of 750 ppm in F1B, F2B and F3B. A conversion factor of 1/10 is considered adequate for this kind of study in this rat strain.

see KCA 5.6.1/1 2006/7013990 Remark: [redacted]1991*) (copied from Monograph of zeta-cypermethrin)*
Cypermethrin - Three Generation reproduction study in rats [redacted] 1982)

Guidelines: Not fully in compliance with the test method B.35 of directive 87/302/EEC or OECD guideline 416 (1983).
Deviations: Males were changed if mating did not succeed after 2 weeks.
GLP: Yes (only attest of study director)
Acceptance: The study was considered acceptable in the EU registration process 2008.
Material and methods: 30 males and 30 females Sprague Dawley rats received in their diet zeta-cypermethrin (batch n° E-6539-78; purity 89.6 %) at 7.5, 25, 100, 375, 750 ppm for 12 weeks prior to mating and throughout the reproduction phase. Stability and homogeneity in food was evaluated and satisfying and food was prepared every one to two weeks.
Findings:

Mortality
P1 generation: in male rats mortality was not substance related. In females, 2 deaths, occurring during lactation, at top dose are considered compound-related. One 100 ppm female rat was found dead on day 28 of lactation period was not considered compound related because there was no clinical observations prior to its death.
F1 generation: At 750 ppm deaths of 24/27 male and of 27/30 females rats was reported.
Clinical signs
P1 males at 750 ppm had soft or liquid feces. Female P1 rats that died at top dose had clinical signs related to substance intake. These effects occurred essentially during lactation.
Necropsy findings in females that were found dead such as urine stained abdominal fur, bedding in the mouth and no feed in the stomach and gastric erosion were considered treatment-related.
F1 generation: at 750 ppm, small pups were hypersensitive to sound, ataxic and had whole body tremors. This group was eliminated from the study at the end of week 3 post weaning. Alopecia occurred at 375 ppm.
In females, the small pups dying at 750 ppm were ataxic, had whole body tremors and clonic convulsions. They had urine-stained abdominal fur, gaseous distended stomach and/or intestines and gastric erosion. This group was eliminated from the study. Localized alopecia was increased in females at 375 ppm during premating, gestation and lactation periods.
Body weights
P1 generation: In male rats, at top dose, bw gains were frequently reduced for the entire premating period resulting in significant reductions in average body weights. Body weight gains were reduced for the 375 ppm group on days 64 to 71. This observation was considered unrelated to treatment because it was a single event followed by a significant increase on days 71 to 79 of the study.
Female rats given the 750 ppm had significant reductions in bw gain during premating and lactation period. Bw was reduced significantly for this group from the completion of the first week of exposure until termination at the end of lactation period. At 375 ppm, females tended to have reduced average bw gains and bw during premating period. Although not affected during gestation, maternal bw gains tended to be reduced for this group during the first 2 weeks of lactation period, and average bw were reduced during the lactation period.
F1 generation: Significant reduced bw occurred at 375 and 750 ppm prior to weaning in males and continued to be reduced through day 99 post weaning and for the 750 ppm through day 22 post weaning (this group was discontinued at this point of the study). Bw gains of males were affected at 375 and 750 ppm. Terminal bw was significantly reduced for the 375 ppm group and this group had significant increase in the relative brain weight.
In females, bw reduction was seen at 750 ppm groups prior to weaning; bw gain was reduced post weaning at 375 and 750 ppm. Average bw tended to be reduced for the 2 top dose groups on day 1-22 through premating period and for surviving 375 ppm group until the end of premating period. Body weight gains were not affected during gestation and lactation at 375 ppm but body weight was reduced during these periods. Terminal bw at 375 ppm was significantly reduced and brain weight was increased.
Food consumption:

P1 generation: was reduced in male rats at 375 and 750 ppm, during the first days of the study. At top dose, reduction was observed throughout the remainder of the premating period.
P1 females had reduced food consumption for the 375-ppm group at the beginning of the premating period. At 750 ppm, food consumption was reduced throughout the premating period. Food consumption was reduced for the 375-ppm group on days 0-6 of gestation period. Food consumption was reduced during the entire gestation
period at 750 ppm. Reduction was also observed during lactation period at 375 and 750 ppm.
F1 generation: food consumption was significantly reduced in males at 375 and 750 ppm during post weaning.
In females, food consumption was reduced at 375 and 750 ppm during the post-weaning period but was not affected during gestation at 375 ppm. Some periods were affected during lactation in this group.
Mating and fertility:
P1 generation: Mating performance of male and female rats of P1 was not affected. Duration of gestation and parturition, gestation indices, implantations, delivered pups, live born and stillborn pups or pup sex ratios was not affected.
F1 generation: at 375 ppm, no effects were seen on the mating performance or fertility of male and female rats. Duration of gestation and parturition, gestation indices, implantations, delivered pups, live born and stillborn pups or pup sex ratios was not affected.

Pup data: see Table 5.6.1-6
F1 generation: The viability and lactation indices were significantly decreased for the 750-ppm. At 750 ppm, litters died before day 28 postpartum. The average number of live pups/litter at weighing was significantly decreased on days 7, 14 and 21 postpartum. The average number of surviving pups/litter was significantly reduced on days 7, 14, 21, and 28 postpartum.
Increased numbers of pups in the 750-ppm group had clinical or necropsy observations related to the compound. Pups were pale, cold to touch, not nursing, weak and/or dehydrated. Necropsy of the 750 ppm pups frequently revealed observations interrelated with their failure to thrive, including evidence of maternal cannibalization, no
milk in the stomach, gaseous distention of GI tract, GI bleeding and incidental urinary tract bleeding.
At 375 and 750 ppm, reduction in pup body weight was observed. These effects first occurred on days 7 and 4-post partum for the 375 and 750-ppm groups respectively.
F2 generation: the 375-ppm group had significantly reduced pup body weights on day 14 and 21 postpartum. Gestation, viability and lactation were unaffected by exposure to 375 ppm. No clinical or necropsy observations for the offsprings were considered effects of the test substance.

Conclusion

NOAEL systemic toxicity parents = 100 ppm (5.9 mg/kg bw/d) based on decreased body weights, body weight gains, clinical signs of toxicity seen at 375 ppm (22 mg/kg bw/day).
The NOAEL reproduction = 750 ppm (43 mg/kg bw/d) for the P1 generation and 350 ppm (22 mg/kg bw/d) for the F1 generation because mortality prevented evaluation of the reproductive performance of the 750 ppm group second generation.
NOAEL developmental toxicity = 100 ppm (5.9 mg/kg bw/d) based on reduced pup body weights in both generations during the lactation periods. Pups mortality was seen at top dose.

CA 5.6.2 Developmental toxicity studies

Alpha-cypermethrin, rat, oral administration by gavage, 0, 3, 9, 15 and 18 mg/kg bw [redacted] 1994a, AL-432-001 and [redacted] 1994a, AL-432-002)

Dose Range Finding Study (AL-432-001)

Guidelines:	Dose range finder for main study. Main study in compliance with the test method B of Directive 87/302/EEC or OECD guideline 414 (1981).
Deviations:	None
GLP:	Yes (no attest of competent authority)
Acceptance:	The study was considered acceptable in the EU registration process 1999.

This study consisted of two parts. The first part was conducted in non-mated females to establish the maximum tolerated dose (MTD) of the test article; the second part was conducted in mated females to investigate the effect of the test article on the pregnant rat and offspring in utero in order to select dose levels for a subsequent developmental toxicity study.
MTD Phase: Groups of three non-mated, sexually mature, female Sprague-Dawley rats were dosed, once daily, orally by gavage, with solutions of alpha-cypermethrin in corn oil vehicle for five consecutive days. Dose levels of 15, 18, 20, 30 and 50 mg/kg were employed.
Mated Phase: Groups of five timed-mated Sprague-Dawley rats were dosed, once daily, by oral gavage, from days 6 through 15 of pregnancy at dose levels of 3, 9, 15, and 18 mg/kg bw/day alpha-cypermethrin in corn oil. A group dosed with the vehicle only served as controls. On day 20 of pregnancy a necropsy was performed. The fetuses were weighed, sexed and subjected to external examination.
Findings:
MTD Phase: Treatment at levels of 20, 30 and 50 mg/kg bw/day was associated with severe changes in clinical condition, including convulsions, ataxia, hypersensitivity to touch and sound, spasms, piloerection, limb splay and hunched posture that were typical pyrethroid-associated effects. The severity of the effects was dose related. Dosing was discontinued prematurely, after the second treatment for these groups, and all animals in the 50 and 30 mg/kg bw/day groups and one animal in the 20 mg/kg bw/day group were sacrificed. In the 18 mg/kg bw/day group, there were similar clinical signs of toxicity as described above, as well as weight loss.
On day 5, prior to dosing, one female displaying severe clinical signs of toxicity was sacrificed. The others were dosed as scheduled. In the 15 mg/kg bw/day group, all three females were dosed for five consecutive days; animals in this group exhibited slight weight loss, and two had observations of piloerection and/or hunched posture. None of the surviving females showed treatment-associated abnormalities at necropsy. The MTD was determined to be 18 mg/kg bw/day.

Mated phase: Clinical signs of treatment at 18 mg/kg bw/day included hind limb splay and unsteady gait. One female treated at 15 mg/kg day also exhibited similar signs. One female in the 9 mg/kg bw/day group in poor clinical condition, was sacrificed on day 16; the condition of this animal was determined not to be treatment associated as similar signs were not seen at higher dose levels. No treatment-related clinical changes were noted in other animals in the 9 mg/kg bw/day group or at lower dose levels. Mean body weight gain in the 18 mg/kg bw/day group was significantly reduced in comparison to the control group over the 6-15 day dosing period. Body weight gains in the groups treated at 9 and 15 mg/kg bw/day were lower during the first half of the dosing period, but the differences were not statistically significant and a compensatory increase was observed in the 15-20 day interval. Body weight gain in the group treated at 3 mg/kg bw/day was similar to that of the control group throughout the dosing period. Similar to body weight gains, mean food consumption values in the 18 mg/kg bw/day group were lower than that of the control group over the entire dosing period, and were significantly lower during days 6-12. Food consumption values in the 15 mg/kg bw/day group were slightly, but not significantly lower between days 6 and 9 only. At the lower dose levels, food consumption values were similar to that of the control group throughout the dosing period. There were no treatment-related abnormalities at maternal necropsy. There were no significant intergroup differences in the mean numbers of corpora lutea, implantations or live fetuses. Pre- and post-implantation losses were increased, as compared to the controls, for all treatment groups and post-implantation losses were statistically significantly increased for the 9 mg/kg bw/day group. These effects were believed, however, to be related to unusually low pre- and post-implantation losses in the control animals and were not considered to be toxicologically significant. There were no effects of treatment on fetal weights or sex ratios.

Conclusion:
Dose levels established for the main study were between 3 and 18 mg/kg bw/day. The highest dose level was selected as a dose expected to elicit minimal maternal toxicity, and the lowest level was selected as a probable "no effect" level with respect to maternal toxicity.

Main study [redacted] 1994a)

Guidelines:	Study in compliance with the test method B of Directive 87/302/EEC or OECD guideline 414 (1981).
Deviations:	None
GLP:	Yes (no attest of competent authority)
Acceptance:	The study was considered acceptable in the EU registration process 1999.

The effects of alpha-cypermethrin on the pregnancy and embryonic or foetal development of the Sprague-Dawley rat were investigated at 0 (control), 3, 9, 18/15 and 15 mg/kg bw/day administered in corn oil by gavage from day 6 to day 15 post mating. The dose level was 18 mg/kg bw/day from day 6 to 9 of pregnancy, and 15 mg/kg bw/day from day 10 to 15 of pregnancy. The study was performed according to US EPA 83-3. The conduct of the study is consistent in all important aspects to OECD 414 (2001) and EC method B.31 (2004/73/EC), with the exception that the test substance was administered solely during the period of organogenesis.

Findings:
Administration of alpha-cypermethrin via gavage at 15 or 18 mg/kg bw/day to pregnant rats during foetal organogenesis elicited maternal toxicity characterised by changes in clinical conditions and reduction in food consumption and body weight gain during the dosing period. Further, a slight reduction in foetal weights was observed at these dose levels most probably being a consequence of the observed maternal toxicity. However, there was no other evidence of embryo- or fetotoxicity or teratogenicity at any tested dose level.

Conclusion:
Based on the described maternal toxicity and embryonal toxicity effects at 15 or 18 mg/kg bw/day the NOAEL for maternal toxicity and embryotoxic/teratogenic effects was considered to be 9 mg/kg bw/day.

Disregarded Developmental toxicity study in rats [redacted] unknown date) (Dossier Gharda)

Guidelines: Study not in compliance with the method B of Directive 87/302/EEC.
Deviations: The route of administration is not defined. Experimental results are not fully described. Sex of foetuses was not determined. Tables describing abnormalities are confusing. No statistical treatment of results.
GLP: No data
Acceptance: The study was not accepted in the EU registration process 1999.

Twenty pregnant Young Charles Foster rats were exposed to alpha-cypermethrin at doses of 0, 5, 10 and 20 mg/kg bw/day on day 6 through day 18 of gestation. Controls were dosed with vehicle only (DMSO). Females were sacrificed on day 20 of gestation. The conduct of the study was not consistent to OECD 414 (2001) and EC method B.31 (2004/73/EC) because the route of administration is not defined, experimental results are not fully described, sex of foetuses was not determined, the tables describing abnormalities are confusing and no statistical evaluation of the results were performed. Therefore, the study is not accepted.
Findings:
The number of litters, body weight of pregnant females, number implants per dam and mean foetal body weight were normal except the number of resorptions increasing with the dose as well as the number of live foetuses which appeared to decrease with the dose. No teratogenic effects were observed.

Conclusion:
This study exhibits severe deficits in the experimental protocol. Therefore, it was not possible to evaluate clearly if alpha-cypermethrin induced abnormalities in foetuses and the study was not accepted for evaluation.

Alpha-cypermethrin, rabbit, oral administration by gavage, 0, 3, 15, 30 mg/kg bw/day ([redacted] 1994b, AL-432-003 and [redacted] 1994b, AL-432-004)

Dose Range Finding Study ([redacted] 1994b)
Guidelines: Dose range finder for main study. Main study was in compliance with the test method B of Directive 87/302/EEC.
Deviations: None
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

This preliminary study in New Zealand white rabbits consisted of two parts. The first part was a study in non-mated females to establish the maximum tolerated dose (MTD). The second part was a study in mated females to investigate the effect of the test article on the pregnant rabbit and offspring in utero in order to select dose levels for a subsequent developmental toxicity study.
MTD Phase: A group of five non-mated, sexually mature, female New Zealand White (NZW) rabbits was dosed, once daily, by oral gavage with solutions of alpha-cypermethrin in corn oil for twenty five days within a thirty day period. The dose levels increased as follows; 10 mg/kg bw/day for days 1 to 5, 15 mg/kg bw/day for days 6 to 10, 25 mg/kg bw/day for days 12 to 16, 35 mg/kg bw/day for days 19 to 23, and 40 mg/kg bw/day for days 26 to 30. On intervening days, the animals were not dosed. Once the MTD was established, a second group of five non-mated females was dosed, once daily, orally by gavage at 35 mg/kg bw/day for seven consecutive days.
Mated Phase: Groups of 5 timed-mated NZW rabbits were dosed, once daily, by oral gavage from days 7 to 19 of pregnancy, inclusive, at dose levels of 5, 15, 25, and 30 mg/kg bw/day alpha-cypermethrin in corn oil. A group dosed with the vehicle only served as controls. On day 28 of pregnancy, animals were sacrificed by caesarean section. The fetuses were weighed, sexed and subjected to external examination.

Findings:
Increasing Dose MTD Phase: During the first two days of dosing at 10 mg/kg bw/day, there were slight reductions in body weight and food consumption values. The animals recovered, however, and there were no further signs of treatment at 10, 15, or 25 mg/kg bw/day. At 35 mg/kg bw/day, one animal appeared ataxic and languid on the first day of dosing, and there was a trend toward a slight decrease in body weight, food consumption and feces production during the five days of treatment at this dosage. These animals recovered in the two off-dose days. At 40 mg/kg bw/day, the animals showed slight fluctuations in body weight and food consumption, similar to the 35 mg/kg bw/day dose group. The MTD was considered to have been reached at 35 mg/kg bw/day. There were no treatment-related abnormalities at necropsy.

Fixed dose MTD Phase: The protocol specified that the animals would be dosed for eight days, however, dosing was discontinued after seven days because of the significant toxicity associated with the treatment. There were no unscheduled deaths, but two animals were sacrificed prematurely (one on day 6 and one on day 7) due to negligible food consumption and marked body weight loss. All animals showed body weight loss and reduced fecal output after one or two doses, which persisted throughout dosing; however, on day 9, two days after cessation of dosing, two of the three surviving females showed a slight body weight gain. There was a marked decrease in food consumption during dosing, as well, with appetite recovery observed for all animals after cessation of dosing. There was a lack of food found in the stomachs of those females sacrificed prematurely, however there were no abnormalities at necropsy that were considered to be related to treatment.
Mated phase: Two females (one in each group at 15 and 25 mg/kg bw/day) were sacrificed prematurely because of low food consumption values and body weight loss. Clinical signs were limited to a reduction in the amount of feces for control and treated animals. Animals in the control, 25 and 30 mg/kg bw/day groups exhibited a mean body weight loss at the onset of dosing. This may have been the result of the low tolerance of the pregnant rabbit to administration of corn oil (vehicle). The weight gains of the animals dosed at 5 and 15 mg/kg bw/day were unaffected by treatment. There was a trend toward further reductions in mean body weights during the latter third of the treatment period for animals dosed with 25 and 30 mg/kg bw/day only. After the conclusion of the dosing period, all affected animals showed a compensatory increase in mean body weight. Food consumption was similarly reduced during the dosing period in animals which exhibited weight loss; a slight reduction in food consumption was also noted during the treatment period for animals dosed at 5 and 15 mg/kg bw/day. Mean food consumption for all groups returned to expected levels at the cessation of treatment. There were no treatment-related abnormalities at maternal necropsy and no apparent adverse effects of treatment on mean numbers of corpora lutea, implantations, live fetuses, or pre- or post-implantation losses. There was no effect of treatment on fetal weight, sex ratio, or the incidence of fetuses with external abnormalities.

Conclusion:
Dose levels established for the main study were 3, 15 and 30 mg/kg bw/day. The highest dose level was selected as a dose expected to elicit minimal maternal toxicity; higher doses were not recommended in light of the toxicity observed at 35 mg/kg bw/day in the preliminary MTD study. The lowest level (3 mg/kg bw/day) was selected as a probable "no effect" level with respect to maternal toxicity.

Main study ([redacted] 1994b)

Guidelines: Study in compliance with the test method B of Directive 87/302/EEC.
Deviations: None
GLP: Yes (no attest of competent authority)
Acceptance: The study was considered acceptable in the EU registration process 1999.

The effects of alpha-cypermethrin on the pregnancy and embryonic or foetal development in the New Zealand White rabbit was investigated at 0 (control), 3, 15 and 30 mg/kg bw/day administered in corn oil from day 7 to day 19 post mating. The study was conducted according to US EPA 83-3. The conduct of the study was consistent in all important aspects to OECD 414 (2001) and EC method B.31 (2004/73/EC), with the exception that less than 20 female animals with implantation sites were investigated, and that the
test substance was administered solely during the period of organogenesis.

Findings:
There was no maternal or developmental toxicity associated with oral administration at 3 or 15 mg/kg bw/day. Administration via gavage of 30 mg/kg bw/d of alpha-cypermethrin to pregnant rabbits during foetal organogenesis caused reduced maternal food consumption and body weights during the latter stages of the dosing period. There was no evidence of embryo or foetal lethality, growth retardation or teratogenicity at any tested dose level.

Conclusion:
Based on the maternal reduced body weight and food consumption the NOAEL for maternal toxic effects is considered to be 15 mg/kg bw/day. Since no embryotoxic and/or teratogenic effects were observed the NOAEL for embryotoxic/teratogenic effects corresponds to 30 mg/kg bw/day which is the highest dose tested.

CA 5.7 Neurotoxicity Studies

EU Dossier update (November 2015) containing an update of data which were not present at the dossier submission in February 2015: The DNT-study under point 5.7.1/3 was not finalized at dossier submission and data on stability, homogeneity and concentration control, pathological examinations of dams and pups and examination of pups brain (weight, length and width) were missing. Furthermore a separate analytical report (Doc ID 2015/1175543) is included which analysed the alphacypermethrin content in the pups, separated into amount in brain and carcass. *The data are combined in chapter CA 5.7.1/3 of this dossier and highlighted in yellow. The methodical details are included in chapter CA 4-Analytical methods.*

Studies evaluated in the draft monograph of rapporteur member state Belgium of September, 1999: Two acute neurotoxicity studies in hens and rats are available for Alpha-Cypermethrin. These studies, in addition with one mechanistic study, have been evaluated by European authorities and Belgium as Rapporteur member state (European Commission Peer Review Program) and were considered to be acceptable. For the convenience of the reviewer, these are summarized below as extracted from the monograph and brief summaries are provided under the respective chapters.

Table 5.7-1: Summary of already peer-reviewed alpha-cypermethrin neurotoxicity studies as available in the DAR (1999)

Study Dose levels	Substance information	NOAEL mg/kg bw/d	LOAEL mg/kg bw/d	Adverse effects at LOAEL	Reference
Neurotoxicity studies					
Acute neurotoxicity study Crl:CD:BR rat, 0, 4, 20 and 40 mg/kg bw/d (gavage, corn oil)	Alpha-cypermethrin (batch No. 021.56)	4	20	neurotoxicity; increased neurologic reactivity	[redacted] 1993, CA 5/13 AL-451-004
Acute neurotoxicity study Hen, 0, 70, 140, 700 mg/kg bw/day (gavage, DMSO)	Alpha-cypermethrin (99%)	-	70	brain inflammation; spinal cord altered cellular pattern; sciatic nerve axonal fibres distension	[redacted] 1989, Gharda[1]
Supplementary studies already reviewed in the monograph of alpha-cypermethrin and at that time discussed under CA 5.8.2					
Subacute neurotoxicity study, rat 10, 20, 40 mg/kg bw/day (gavage, DMSO)	Alpha-cypermethrin (batch No. 7; 96.6%)	10	20	increase of beta-galactosidase activity in sciatic posterior tibial nerve, trigeminal ganglia and nerve	[redacted] 1983, AL-451-002

[1] These studies are not BASF proprietary, but owned by Gharda, Chemical Ltd. Bombay, a further notifier for Annex I listing of alpha-cypermethrin in 1999

The summary of these neurotoxicity studies is still valid:
In hens, alpha-cypermethrin at doses from 70 to 700 mg/kg bw produced inflammatory reaction in brain, disruption of cellular pattern in spinal cord and distension and disruption of axonal fibres in sciatic nerve. Alpha-cypemiethm is toxic for the CNS and peripheral motor nerves.

The acute neurotoxicity of alpha-cypermethrin was studied in rats from 4 to 40 mg/kg bw. Clinical signs of neurotoxicity were apparent from 20 mg/kg bw onwards. Male rats were more susceptible than female rats and presented abnormal splayed gait, thrashing, prostration, vocalization, piloerection, hunched posture, unkempt appearance, soiled/stained body areas and diarrhea. Increased neurologic reactivity was seen in most males. Animals recovered by day 7. Motor activity was not affected. Very slight to slight sporadic fiber degeneration was shown in the proximal part of the sciatic nerve. In this study the NOAEL is 4 mg/kg bw.

Biochemical evidence of damage to the sciatic posterior tibial nerve, trigeminal ganglia and nerve were reported by measuring increases in beta-galactosidase enzyme activity after 4 weeks treatment with alpha-cypermethrin at doses of 20 mg/kg bw/day. The NOAEL in this study is 10 mg/kg bw/d.
Neurodevelopmental toxicity of pyrethroids was comprehensively discussed in the ECCO Peer review meeting - Full Report on alpha-cypermethrin ([see KCA 5.7/1 AL-901-031], page 164-172 of 222, presented as copy in CA 5.7.1) based on Literature data. The discussed literature data are for the convenience of the reviewer summarized below in tabular form (see Table 5.7-2), a short summary of the some points is presented below:

Table 5.7-2: Summary of already peer-reviewed literature data on developmental neurotoxicity as available in the ECCO Peer review meeting - Full Report on alpha-cypermethrin (DocID AL-901-031, page 164-172 of 222)

Authors	Exp.conditions	Endpoints	Results	ECCO Comments
Cantalamessa et al, 1998	Cyp treatment from PND 10-16, Wistar, rats 1 mg/kg bw/d	Dopamine DI and D2 like receptor assay in kidney	↑ density of receptors D1 in 30, 60, 90 day old rats	Dopamine exerts renal actions including diuresis. No effects seen in the 3 generation rat study at 25 mg/kg bw/d
Husain et al, 1992	Cyp in formulation, Rats 15 mg/kg bw/d GD 5-21	Behavioral teratogenicity	Delayed fur Develop., incisor eruption, eye and ear opening, reduced surface righting reflex	Range of days of occurrence and not a mean. Effects obtained from 10 pups/group (1 pup from each of 10 litters/group). Parameters should be determined for litters
Malaviya et al., 1993	Cyp, 15 mg/kg bw/d from GD 5-21. Nursing mothers, day 1 PN up to 3 week	Brain enzymes : MAO, AChE, Na^+,K^+ ATPase	Exposure *in utero:* no effect Lactation exp: ↓ AChE, Na^+,K^+ ATPase and ↑ level dopamine and muscarinic receptor of striatal membrane	Fenvalerat also reported in this study has different effects although it is a type II pyrethroid. No neurobehavioral effects in 3-generation rat study at neurotoxic maternal doses.
Kavlock et al.	Decamethrin (type II) 2.5 or 5 mg/kg bw/d GD 7 to LD15	Neurobehavioral study in litters	Neurotoxicity in dams at 5 mg/kg No effects in neurobehavioral parameters	additional doubt on study by Husain
Eriksson and Fredriksson	NMRI mice pups with bioallethrin 0.7 mg/kg bw/d (type I) or deltamethrin 0.7 mg/kg bw/d (type II) from PND 10-16	Density muscarinic receptors in brain; motor activity in adult	↓Density muscarinic receptors in brain; ↑ motor activity	Results not reproductible for same compounds at same laboratory. Inconsistent results and opposite to the other study

Authors	Exp.conditions	Endpoints	Results	ECCO Comments
Muhammad and Ray	NMRI mice pups with bioallethrin 0.7 and 3.5 mg/kg bw/d (type I) or deltamethrin 0.7 and 3.5 mg/kg bw/d (type II) from PND10-16	Density muscarinic receptors in brain; motor activity in adult	Muscarinic receptors density: inconsistent; Minimal changes in motor activity in some experiments and not in others. No dose related effects	Changes in muscarinic receptor density and motor activity changes found by Eriksson and Fredriksson not confirmed
Bayer AG	Inhalation with several yrethroids in NMRI mice PND10-16	Spontaneous motor activity; muscarinic receptor density at 17d and 4 month	Slight ↑ in muscarinic receptor density on PND17 not correlated with changes in spontaneous motor activity. No effect in adults	Neurobiochemical changes are likely not biologically significant
IVA, 1994		Neurotoxicity of pyrethroids to developing animals: retrospective analysis	Alpha-cyp or cyp are not selectively toxic to developing offsprings : rearing, nursing, behavior of dams, social and sukling behavior of neonates not affected except at toxic parental doses	Majority of NOEL offspring ≥ NOEL parental tox. No functional or morphological changes in nervous system
Sheets, 2000	Rats, cypermethrin 9, 19, 38 mg/kg bw, 21 day old rats, comparison with adult rats	Auditory startle response	38 mg/kg bw: ↓ startle response of 50% comparable to adult 50% reduction	
Conclusion : No additional studies are necessary.				

Sheets (Neurotoxicology, 21(1-2): 57-64, 2000) showed that neonates are more sensitive than adults to acute lethal dose of certain pyrethroids but not to much lower levels that are relevant for dietary risk assessment. This higher sensitivity is not based on differences at the target sites in the brain of the neonates. Studies with Deltamethrin showed that at the respective LD50 dose, the same brain level was observed in adults and weaning rats, which received a seven time lower dose. This indicates that the main age related difference only occur at dose levels that exceed the neonate`s capacity for detoxification.

Furthermore the vulnerable periods during ontogenesis of the CNS were discussed. They can be divided into 2 major courses of events:

1. Early brain development: brain acquires its general adult shape
2. Brain growth spurt: rapid fundamental changes including maturation of axonal and dendritic outgrowth;

In humans, the brain growth spurt occurs maximally at the 3rd trimester of pregnancy up to 2 years of life. In mouse and rat, this period is neonatal spanning the first 3-4 weeks of life. Therefore early postnatal exposure in the rodent (postnatal day (PND) 10-17) encompasses a time span equivalent to peri-neonatal exposure in the human.

Additional support which negates the likelihood of developmental neurotoxic activity is coming from the developmental toxicity studies with alpha-cypermethrin and the developmental and the 3–generation study with cypermethrin. Results indicate that neither alpha-cypermethrin nor cypermethrin is a selective developmental toxicant or a teratogenic agent in either the rat or rabbit. Because neither alpha-cypermethrin nor cypermethrin is a selectively toxicant to the developing fetus or offspring, there is no increased sensitivity of developing offspring following prenatal or postnatal exposure to alpha-cypermethrin or cypermethrin. In the absence of any selectivity or increased sensitivity to the developing fetus or offspring, a developmental neurotoxicity study with alpha-cypermethrin is not warranted.
This was also confirmed by a pyrethroid ad hoc working group sponsored by Industrieverband Agra e.V. which developed a white paper and discussed the potential neurotoxicity of pyrethroids to developing animals. Taken together, the retrospective analysis presented in this white paper provides strong evidence that treatment of lactating and/or pregnant females with pyrethroids is not associated with developmental neurotoxicity.

In the end it was concluded in the Review Report (SANCO/4335/2000 final from Feb. 2004 under the Header “List of studies to be generated:”
“*No further studies were identified at this stage considered necessary in relation to the inclusion of alpha-cypermethrin in Annex I under the current inclusion conditions.*
… As for other pyrethroids, confirmatory data to further address concerns related to potential developmental neurotoxicity should be generated, when internationally agreed testing protocols are available.”
Based on the available data, the following endpoint was determined during the last Annex I listing of Alpha-Cypermethrin concerning neurotoxicity/delayed neurotoxicity:

Neurotoxicity / Delayed neurotoxicity

Effects observed	Alpha-cypermethrin is toxic for CNS and peripheral motor nerves; neurobehavioral changes are reversible within 3 days following single dose
Acute rat study	NOAEL = 4 mg/kg bw (in corn oil)
4 week oral rat study	NOAEL = 10 mg/kg bw/day (DMSO)

Studies submitted in this AIR 3 dossier (Part I: peer-reviewed studies from other DARs):
To address the request of a developmental neurotoxicity study expressed in the Review report of alpha-cypermethrin (2004) when internationally agreed testing protocols are available, it is considered appropriate to bridge to the dietary developmental neurotoxicity study with zeta-cypermethrin. This study has been summarized and evaluated in the DAR of zeta-cypermethrin (2008) by the rapporteur Member state Belgium. This study as well as a dietary placental and lactational transfer study in rats (presented in CA 5.8.2) are not data protected anymore and fulfill the criteria to wave a developmental neurotoxicity study with direct pup dosing because zeta-cypermethrin has been shown to be transferred in utero as well as via milk. Thereby a continuous exposure of the developing offspring is guaranteed and direct pup dosing should be not needed. Based on the previously presented general bridging approach (see CA 05.00) this study is considered to be valid for alpha-cypermethrin, too.

Within the EFSA conclusion of zeta-cypermethrin (EFSA Scientific Report (2008) 196, p. 15) it is stated: *"A developmental neurotoxicity study in rats was summarized in the DAR showing a maternal and developmental toxicity NOAEL of 9 mg/kg bw/day based on reduced bodyweight gain. Zeta-cypermethrin did not show any developmental neurotoxic potential.*

Placental and lactational transfer was investigated after dietary exposure of dams. Zeta-cypermethrin was identified in milk following dietary administration indicating that a transfer occurred from food to milk and that exposure of pups occurred via milk."
Based on this study it is concluded that the related alpha-cypermethrin is not suspected to show any developmental neurotoxic potential.

This conclusion is furthermore supported by evaluations published by different authorities that investigated the developmental neurotoxic potential of pyrethroids and that all came to the conclusion that possible DNT effects induced by pyrethroids are covered by the acute neurotoxicity and medium term studies, since DNT effects from acceptable OECD TG 426 performed studies are taking place at higher LOAELs than acute neurotoxicological effects. Therefore additional DNT study according to OECD TG 426, if such a study is not present, is not necessary.

- EFSA Scientific Opinion: Potential developmental neurotoxicity of deltamethrin; EFSA Journal (2009) 921, 1-34; (online available under the following link: http://www.efsa.europa.eu/de/efsajournal/doc/921.pdf)

However, in 2013 the Rapporteur UK published the DAR of Beta-cypermethrin with a developmental neurotoxicity study (Vol. 3, B.6.7 d) split up into 2 administration szenarios:
Szenario I consisted of an oral gavage study of dams from GD 6 to PND 21 and pup exposure via milk (a transfer of beta-cypermethrin into milk was shown in the corresponding 2-generation study). The dams within the developmental neurotoxicity study showed clinical signs and body weight reduction at 12 mg/kg bw whereas pups showed increased motor activity only at the maternal toxic dose of 30 mg/kg bw and only on PND13. The study clearly indicated that although pups are sensitive to the neurotoxic effects of beta-cypermethrin, direct lactational transfer through milk is not at sufficient quantities to induce adverse effects in pups.
Szenario II consisted of an oral gavage study of dams from GD 6 to PND9 and direct pup dosing from GD10 to GD16 at 0.5 mg/kg bw. The direct dosing of pre-weanling pups produced sever clinical signs of toxicity, body weight reduction, clonic convulsions, altered grooming and deaths already at a dose of 0.5 mg/kg bw, but only at the time of direct pup treatment.

Based on the results the rapporteur UK concluded: *"Direct dosing of pre-weanling pups with beta-cypermethrin is a highly unrealistic exposure technique and* ***the findings in this section of the study are not considered relevant to a human risk assessment for infants*** *who will be either breast or bottle fed."*

However, this opinion was changed within the Peer review meetings on beta-cypermethrin where it was argued that relevance for human risk assessment is given because

1. today babies are not only breastfed but receive additional exposure via bottle milk, baby food or air drift as residents.
2. Neurological development of infants and toddlers partly corresponds to early post-natal development in rodents

Taking a look into the Meeting minutes (3717prr public.pdf available online via: http://registerofquestions.efsa.europa.eu/roqFrontend/outputLoader?output=ON-3717) it appears that mainly 2 member states were arguing for the use of these endpoints.

Finally, the EFSA conclusion on beta-cypermethrin (EFSA Journal 2014; 12 (6):3717) reported: *"The majority of the experts agreed that the findings after gavage of pups were relevant for human risk assessment. It is noted that the toxicity of the other cypermethrins might need further evaluation on the basis of these new data of developmental neurotoxicity with beta-cypermethrin."*

In the following Table 5.7-3 the results of developmental neurotoxicity studies with zeta- and beta-cypermethrin are summarized as presented in the respective DARs.

Table 5.7-3: Developmental neurotoxicity endpoints for beta- and zeta-cypermethrin

Study	Test substance information	Endpoints		Reference
		NOAEL (mg/kg bw/day)	**LOAEL (mg/kg bw/day)**	
Developmental neurotoxicity, rat				
Rat developmental neurotoxicity Dams/pups (study I): 3, 12, 30 mg/kg bw/day Pre-weanling pups (study II): 0.5 mg/kg bw/day oral, gavage vehicle: 1% methylcellulose/ 0.1% polysorbate 80	Beta-cypermethrin: batch No. PL9511038; 97.6%	Dams: 3 mg/kg bw/day	12 mg/kg bw/day clinical signs, body weight	Adapted from DAR beta-cypermethrin (2013) and supplemented by EFSA conclusion (2014) data
		Pups: 12 mg/kg bw/day	30 mg/kg bw/day increasing motor activity count	
		Pre-weanling pups direct dosing: <0.5 mg/kg bw/day	0.5 mg/kg bw/day Clinical signs, decreased body weight, tremors, clonic convulsions, altered grooming and death	
Rat developmental neurotoxicity 50, 125, 300 ppm (3.6, 9, 21.1 mg/kg bw/day) (dietary administration)	Zeta-cypermethrin: batch No. PL03-0427; 81.8%	Dams: maternal: 9 mg/kg bw/day neurotoxic: 21.1 mg/kg bw/day	Dams: maternal: 21.1 mg/kg bw/day body weight, body weight changes and food consumption neurotoxic: > 21.1 mg/kg bw/day	Adapted from DAR zeta-cypermethrin (2008) and supplemented by EFSA conclusion (2008) data
		Pups: developmental: 9 mg/kg bw/day neurotoxic: 21.1 mg/kg bw/day	Pups: 21.1 mg/kg bw/day body weight, body weight changes neurotoxic: > 21.1 mg/kg bw/day	

While the exposure via the dam showed for zeta- and for beta-cypermethrin comparable results with no increased sensitivity of developing offspring following prenatal or postnatal exposure, the direct gavage of pups showed drastically higher susceptibility of the pups.

BASF is of the opinion that this higher sensitivity is predominantly due to a substantial double exposure and the artificial test system which is a highly unrealistic scenario for human exposure as it is a bolus administration. There are many reasons why such an exposure leads to artificial findings at low doses that are not relevant under normal conditions and we fully share the scientific opinion of UK that this study is designed for hazard assessment in case of non exposure of pups within the lactation phase and should not be relevant for human risk assessment.

Studies submitted in this AIR 3 dossier (Part II: not peer-reviewed studies)
However, in bilateral discussions with the Rapporteur Belgium it was agreed to perform a targeted DNT study with direct dosing of alpha-cypermethrin to pups focusing on the effects seen in the developmental neurotoxicity studies performed with beta-cypermethrin in order to address the concerns of the Rapporteur. The findings of this study are comparable to those described in the beta-cypermethrin study and demonstrate the drastic increase of toxicity by this artificial form of administration which is not considered relevant for the human risk assessment.

In addition a 90-day study performed in 1994 that was not submitted in the former registration process under the aegis of Cyanamid is now presented for completeness in detail.

Table 5.7-4: Not peer-reviewed neurotoxicity studies with alpha-cypermethrin

Study	Dosages (mg/kg bw/ day) Test substance information	NOAEL (mg/kg bw/day)	Effect at LOAEL (mg/kg bw/day)	Reference
90-day feeding study Crl:CD(SD) BR rat 0, 50, 250, 500 ppm	M: 0, 3.7, 17.9 and 36.1 F: 0, 4.2, 21 and 42	systemic: 3.7 / 4.2 (50 ppm) neurotoxic: 36.1 / 42 (500 ppm)	17/ 21 (250 ppm) Transient reduced food intake, altered hematology parameters neurotoxic: > 36.1 / 42 (500 ppm)	1994 CA 5.7.1/4 AL-425-007 **New data**
Rat developmental neurotoxicity with direct pup dosing PND 10-21 Wistar rats; oral, gavage; vehicle:1% CMC	cohorte I: 0.5, 2, 5 mg/kg bw/day dams and pups; cohorte II-IV: dams: 0.5, 2 mg/kg bw/day pups: 0.25 mg/kg bw each alpha-cypermethrin; 99.2%; PMAM000622	Dams: 5 mg/kg bw	Dams: > 5mg/kg bw No clinical effects	CA 5.7.1/3 ~~2014/1275121~~ 2015/1001621 & Results of the Analytical Report 2015/1175543 (CA 4.1.2/3) **New study**
		Pups (lactational exposure): 5 mg/kg bw	Pups (lactational exposure): >5mg/kg bw No clinical effects (PND 1-9)	
		Pups (direct dosing) Approx.. 0.25 mg/kg bw; (in case dams are dosed < 0.5 mg/kg bw) Calculated: 0.22 mg/kg bw	Pups (direct dosing): 0.25 mg/kg bw; (dose of dams 0.5 mg/kg bw) Calculated: 0.262 mg/kg bw Effect: neurotoxic signs (slight tremors & twitching)	

The **90 day feeding study** in SD rats showed systemic toxicity in form of reduced food intake and altered hematological parameters at the mid dose but no neurotoxicity was observed up to the highest dose of 36 mg/kg bw.

In the rat developmental neurotoxicity study with direct pup dosing the data of beta-cypermethrin were confirmed. Alpha-cypermethrin did not induce neurotoxicity in dams or in pups prior to the onset of direct pup dosing up to a dose of 5 mg/kg bw/day. With the onset of direct pup dosing clinical signs of acute neurotoxicity were induced in pups at a dose level of 0.5 mg/kg bw while higher doses (2 and 5 mg/kg bw) induced mortality after the first bolus application. A high rate of pups that died revealed necropsy observations (gas bubble in the stomach or blood coagulum in renal pelvis). A 50% reduction of the pup dose to 0.25 mg/kg bw/day - while remaining the pre-treatment of dams until PND 8 at 0.5 and 2 mg/kg bw/day - resulted in similar signs of neurotoxicity, however reduced in incidence and severity in a maternal-dose dependent manner. This is indicative for a substantial exposure via milk. Apart from these acute neurotoxic symptoms, pup development was unaffected in all test groups. The transient character of clinical signs with no other indication of developmental changes is furthermore a proof of acute and not developmental neurotoxicity.

The analytical determination of alphacypermethrin in PND 4 and PND 10 pups confirmed the lactational transfer and substantiated the lack of neurotoxic effects prior to direct dosing: it could be demonstrated that the pup body burden is maternal-dose dependent and measureable amounts were still detectable after a 2 day period without maternal treatment. Furthermore, alphacypermethrin was shown to be primarily stored in the carcass with no relevant findings in the brain after lactational transfer. Based on the quantitative determination of the alphacypermethrin in PND 4 and PND 10 pups, under consideration of the bioavailability of 46 %, the LOAEL is calculated to be 0.265 mg/kg bw, while the NOAEL is calculated to be 0.22 mg/kg bw.

A further indication that double exposure via milk is crucial for the reported clinical signs of neurotoxicity comes from the open literature with cypermethrin and is discussed in CA 5.8.2/8 (Doc ID 2007/1070386). This publication reports lack of any neurotoxic clinical signs in pups gavaged with 1.5 mg/kg bw Cypermethrin from PND 10 to PND 16. The main difference in this report is that pups were reared by unexposed dams.

Due to clear indications for substantial double exposure in this study and based on the extreme form of application, BASF does not consider the DNT study endpoint after direct gavage as relevant for risk assessment but will use the endpoint generated in the dietary DNT study with zeta-cypermethrin based on the following reasons:

Reasoning for the appropriateness of dietary DNT studies for cypermethrins

What was the argument for demanding pup exposure via direct gavage with beta-cypermethrin? It was the example of Carbofuran which was mentioned exemplarily within the peer review meetings of beta-cypermethrin that was assessed on the basis of such a study.
Carbofuran shows nearly no accumulation potential in fat and therefore extremely low amounts in milk. Residue levels in fat and milk of ruminants amount for 0.0003 and 0.000083 mg/kg, respectively. So, lactational transfer is highly limited with carbofuran and the investigation of the impact of this substance on newborns within the most vulnerable phase of brain growth sprint is not possible without direct dosing. Here, a DNT study with direct pup dosing is reasonable to investigate the hazard. According to the OECD Guideline 426 for DNT studies it is stated that: "*direct dosing of pups should be considered in those cases where there is a lack of evidence of continued exposure to offspring*."

The case is different for the group of cypermethrins. Both zeta-cypermethrin and beta-cypermethrin are mentioned in the respective EFSA conclusions to have accumulation potential in fat. Residue levels in fat and milk of ruminants amount for ≤0.02 and <0.005 mg/kg for zeta-cypermethrin; and 0.044 and ≤0.002 mg/kg for beta-cypermethrin, respectively. Thereby the residue levels are approximately 66-133 fold higher than for Carbofuran.
In utero and lactational transfer in rats has been shown both for zeta-cypermethrin and beta-cypermethrin, and there is no reasonable argument that a lactational transfer would not also be expected for alpha-cypermethrin.
Indirectly a lactational transfer has been shown with the current DNT study with alpha-cypermethrin because the maternal pre-exposure with 0.5 or 2 mg/kg bw resulted in a dose dependent exacerbation of the clinical symptoms of the pups at the start of direct gavaging, although all pups were dosed at the same level of 0.25 mg/kg bw. This is only explainable under the assumption that the exposure via milk resulted in a dose-dependent pre-exposure of the pups. Further indications of lactational transfer are coming from cattle studies with alpha-cypermethrin (see CA 6.4.2)

As mentioned before, the two major concerns with regard to the beta-cypermethrin developemental neurotoxicity study (direct pup dosing) were:

1. Neurological development of infants and toddlers partly corresponds to early post-natal development in rodents
2. today babies are not only breastfed but receive additional exposure via bottle milk, baby food or air drift as residents.

These concerns are addressed in the following:

Point 1:
A bolus administration in rat at PND 10-17 covers a timespan of human brain development that to a great extent takes place already in utero and that is mainly completed up to birth. For example is the extent of neurogenesis, synaptogenesis or myelination of early postnatal rodents less developed and partly comparable to the respective extent found in humans at birth [see KCA 5.7/2 2006/1051313]. The predominant purpose of direct pup dosing is to ensure pup exposure in those cases where exposure during lactation in animal testing is definitely not given, i.e. exposure of the animal (rat) during the most vulnerable time of brain spurt (PND8 to 14) is not given and therefore effects in humans until birth are not covered. The aim of direct pup dosing is therefore a hazard based approach to get valuable information about substance-related impairment of the brain development during pregnancy and not to simulate the “bolus administration” during breast feeding. In cases where lactational exposure is given, this continous exposure is more relevant to investigate a substance induced effect than the artificial pup dosing with all its secondary consequences.

Point 2:
The concern that babies may be exposed to a relevant extent in a residential situation should be ruled out. Exposure via the inhalation route will be limited. Given the low application rate (maximum of 30 g active substance/ha) in combination with the low vapour pressure of alpha-cypermethrin (3.8 x 10^{-7} Pa at 20°C) inhalation exposure is considered irrelevant. This has also been demonstrated by air concentration measurement in an environmental setting which suggests air concentrations higher than should ever be expected outdoors. Detailed information has been provided in MCP 7.2.2 of the representative preparation BAS 310 55 I.
Exposure via the dermal route is considered negligible too, because babies will have limited activities outdoors in areas that may have experienced contamination via spray drift. Therefore both kinds of exposure scenarios are considered of low relevance which is in full detail addressed in the risk assessment of bystanders and residents (see MCP 7.2.2).

Quite interesting is a comparison of rat exposure vs. human exposure via milk.
The study of dietary lactation transfer of zeta-cypermethrin at 50, 125, 300 ppm in rats from Gestational day (GD) 6 to PND 21 revealed plasma levels half as high as the corresponding dams at PND5 and 21 [see CA 5.7.1/2 2013/1418020]. The measurement of zeta-cypermethrin in milk following dietary administration at 125 and 375 ppm from GD 6- LD17 [see CA 5.7.1/2 2013/1418020] revealed the following mean concentration in milk (see Table 5.7-5). These mean milk concentrations can be used to roughly estimate the mean substance uptake following the equation and parameters used in model simulation for lipophilic substances in rats, published by Lehmann et al., 2014, [see KCA 5.7/3 2014/1320560].

Table 5.7-5: Rough estimation of mean zeta-cypermethrin uptake based on mean concentrations in milk (ppm)

Endpoints/dose	***0***	***125 ppm***	***375 ppm***
Compound ingestion *during gestation Day 6-20 (mg/kg bw/d)*	*0*	*8.59*	*24.38*
Compound ingestion *during lactation Day 1-17 (mg/kg bw/d)*	*0*	*16.71*	*47.73*
Mean zetacypermethrin in milk (ppm)			
Day 4; *Pup ingestion week 1: 3 gr milk/day;* *Mean pup weight week 1: 6,6 gr*		*0.58*	*7.86*
Day 11; *Pup ingestion week 2: 5.4 gr milk/day* *Mean pup weight week 2: 14 gr*		*3.9*	*10.46*
Day 17; *Pup ingestion week 3: 5.9 gr milk/day* *Mean pup weight week 3: 28 gr*		*3.17*	*11.55*
Mean zetacypermethrin uptake (mg/kg bw/day)*			
Day 4		0.26	3.57
Day 11		1.50	4.03
Day 17		0.67	2.43

*Mean zeta-cypermethrin uptake is calculated as mean concentration in milk (ppm) x ingestion rate [kg milk /day]/ pup body weight [kg]

Based on these values, which are in comparison with the data generated in the range finder study for the developmental neurotoxicity study rather underestimations at day 4 and day 17 ([see KCA 5.7/1 AL-901-031], Table 5.7.1-1 the dietary maternal exposure at 375 ppm is considered the NOAEL for developmental neurotoxic effects) resulted in peak levels at around PND 11 of up to 1.5 mg/kg bw/day and 4.03 mg/kg bw. The main developmental neurotoxicity study, which was performed at the same dose levels, showed reduced litter weight and "*occasional statistically significant differences were obtained in some offspring behavioral parameters and in one of 32 brain morphometric measurements of top dose pups, but these apparent alterations did not occur to a degree or in a manner suggesting a compound-related pattern of developmental neurotoxicity" [see KCA 5.7/2 2006/1051313 and Table 5.7.1-2]*. In conclusion the uptake of doses up **to 4.03 mg/kg bw/day** did not induce developmental neurotoxic effects.

In comparison to that, human exposure scenarios via lactation or bottle milk / baby food show a definite lower level of exposure. According Commission Directive 99/39/EC baby food is required to contain no detectable levels of pesticide residues, meaning not more than 0.01 milligrams of pesticide residues per kilogram. Data from the "2011 European Union Report on Pesticide Residues" (EFSA Journal 2014; 12(5):3694, online available: http://www.efsa.europa.eu/de/efsajournal/doc/3694.pdf) indicate that from 1796 surveillance samples of baby food only 3 samples showed cypermethrin residues at a level of 4-5 µg/kg.

Human breast milk concentrations of cypermethrin are available in the open literature from areas where pyrethroids have been widely used for agriculture and disease control. In Table 5.7-6 human breast milk concentrations from Brazil and Colombia (from Corcellas et al., 2012; [see KCA 5.7/4 2012/1367722]) as well as Mozambique (taken from Feo et al., 2012, [see KCA 5.7/5 2012/1367723]) are presented together with concentrations found in baby food. Two of the given milk concentrations, namely Rondonia (2003) and Mosambique (2002), are pool data considered to represent a worst case scenario because the milk samples were taken after epidemic years in which pyrethroids were applied for dengue control at an extensive level. According to the WHO's practitioner's guide (WHO, 2003: Space spray application of insecticides for vector and public health pest control – a practitioner's guide. Geneva, World Health Organization, online available at: http://whqlibdoc.who.int/hq/2003/WHO_CDS_WHOPES_GCDPP_2003.5.pdf) the frequency of indoor treatments can vary widely with the country or geographical area, from annual or occasional treatment to weekly treatments in epidemic situations and disease outbreaks. In addition, the milk concentration from human breast milk samples is given for Columbia and Rondonia in 2006, which were taken in the years after installation of approved guidelines of pesticide use to control dengue in a national program. In all situations, the use and the exposure is considered to be higher than that considered realistic in case of agricultural use.

Table 5.7-6: Lactational exposure levels in humans*

Human situation	Cypermethrin						
data	Baby food	Brazil, Rondonia (2003)*	Brazil, Rondonia (2006)*	Columbia*		Mosambique (2002) **	
		mean	mean	mean	max	mean	max
Concentration of Cypermethrin in milk fat (ng/g fat)		96	4.14	4.25	16.4	54	160
Mean lipid weight in milk [%]		4.0%	4.0%	2.48%	6.43%	4.4%	
Milk levels [µg/kg milk]	5	3.84	0.17	0.11	1.05	2.4	7.0
Estimated daily intake [µg/kg bw]	0.87	0.67	0.02	0.02	0.18	0.42	1.23

*Corcellas et al., 2012; Env. International 47, 17-22, [see KCA 5.7/4 2012/1367722]
**Feo et al., 2012, Env. International 38, 67-72 [see KCA 5.7/5 2012/1367723]
Baby food data: EFSA Journal 2014;12(5):3694; online available; see link in text above

The highest mean cypermethrin residue value was found in the post epidemic Brazilian pool data (10 individuals) from 2003 with a mean concentration in milk fat of 96 ng/g fat (see Table 5.7-6). An estimation of the **maximal value** in this pool sample, considering the highest ratio between mean and max value found in the dataset (Columbia: 16.4 / 4.25 = 3.8), leads to an **estimated maximum value of 370 ng/g fat**. Applying a mean lipid weight in human breast milk of 4% ends up in an **estimated max value of 15 µg/kg milk**.

The estimated daily intake (EDI) for infants of 1 month age can be calculated following WHO recommendations based on the following equation: EDI = C*F*Mb;
with C=concentration in milk fat [ng/g lipid weight]; F =fraction of fat in breast milk [%]; Mb= daily consumption of milk taken as 0.175 kg milk / kg bw / day (WHO parameter).

The EDI is calculated for the pool data and given in Table 5.7-6 in the last line. The worst case exposure for infants of 1 month age based on the estimated max value of 15 µg/kg milk would result in an **EDI_{max} of 2.6 µg/kg bw/day**. This highest estimated daily intake for human infants is by a factor of 1500 below the estimated pup exposure of 4 mg/kg bw realized in the developmental neurotoxicity study with zeta-cypermethrin at 375 ppm that did not induce neurotoxicity.

Further human breast milk pool data from years after installation of approved guidelines of pesticide use to control dengue in a national program demonstrate the drop in cypermethrin concentration in human breast milk when application is done controlled but still with the objective of effective disease control (see Table 5.7-6: Rondonia, 2006 and Columbia). The highest value is represented by the Columbia dataset with a maximal content of 16.4 ng Cypermethrin/g fat. This maximal value is in addition by a factor of 22 lower than that considered as worst case scenario calculated above.

Otherwise, **babies fed with bottle milk will**, even in the hypothetic case of daily exposure to contaminated bottle milk, stay below an **EDI of 1 µg/kg bw/day.** This value is calculated based on the highest residue level found according to the "2011 European Union Report on Pesticide Residues" in 0.2% of probed bottle milk samples. In this respect also here the dietary DNT study can be assumed to be already a worst case scenario that completely covers the human lactational exposure via the different sources.

In conclusion, the concern that babies are exposed not only via breast milk but receive additional exposure via bottle milk, baby food, hand to mouth exposure or air drift as residents is adequately addressed via a normal DNT study in which the exposure of rat pups is at least 1500 times higher than that expected for newborns under worst case scenarios.
Further arguments are discussed in the following that substantiate the limitations of direct pup dosing for the use in human risk assessment of cypermethrins:

- While babies are normally breast- or bottle-fed all 2-4 hours, direct pup dosing is done once a day as bolus administration. This bolus administration leads to artificially high plasma peaks, which is crucial in a case where an effect is related to peak concentrations at the target organ.
- By this bolus administration the complete metabolic system is easily overwhelmed, especially for CYP P450 enzymes which are only little active in the rat at birth and are mainly responsible for cypermethrin detoxification ([see KCA 5.7/7 2009/1130987] Scollon et al., 2008). In humans, 1/3 of the adult enzyme capacity of CYP P450 enzymes is already available at birth [see KCA 5.7/2 2006/1051313] so that low levels of exposure are detoxified.
- The development of the blood brain barrier in humans starts in utero and is considered present at birth, whereas in rats the permeability of the blood brain barrier decreases during the first few weeks after birth to exert full maturation not before PND20.
- The volume of distribution of cypermethrins in neonates is related to the body fat content and rat newborns have less body fat than babies.
- The kind of administration in combination with removal from the dams is highly stressful to the pups and can negatively affect their susceptibility and potentially shows effects on the behavior of the pups [see CA 5.8.2/8 2015/1001752].
- Further critical points with bolus administration of cypermethrins are the volume- and vehicle- dependent toxicity which is also found in adult animals.
- Last but not least there are investigations that indicate that the relevant $Na_v1.3$ sodium channel, which is the principal isoform expressed in the developing brain, is significantly more sensitive in rats than in humans [see Reference in CA 5/2 2012/1367222].

In conclusion, direct pup dosing in rats is prone to produce artificial high plasma concentrations with all its worst case consequences but does not reflect the relevant exposure for human risk assessment.

Consequences of artificial high plasma concentrations with regard to metabolic capacity in rat and a comparison with humans:

The plasma concentration of alpha-cypermethrin is the most important factor for its neurotoxic action because the concentration at the sodium channel relates to the extent of toxicity. Two physiological processes contribute to the concentration: a) distribution and b) metabolic degradation. Distribution within the body mainly happens in fat, and alpha-cypermethrin molecules that are stored in fatty tissue are not available to interact with the sodium channels. Therefore sensitivity to alpha-cypermethrin can be considered to decrease within the first 2 month of child growth due to the steady increase of body fat. Pyrethroid metabolism is mainly based on carboxylesterases and P450 enzymes in general. Age-dependent differences in metabolic capacity are largely responsible for the juvenile susceptibility.

In rats the capacity to detoxify Typ II pyrethroids increases steadily within the first 90 days. This was exemplarily shown with deltamethrin in postnatal day 10, 21, 40, and 90day old Sprague Dawley rats [see KCA 5.7/6 2010/1232432]. Doses of 0.4, 2, 10 mg/kg bw led to dose dependent increase but a age dependent decrease of brain concentrations. The following two figures are taken directly from the literature.

Brain DLT Toxicokinetic Parameter Estimates in Orally-Dosed PND 10, 21, 40 and 90 Rats

	Age (PND)	Dosage (mg/kg)	C_{max} (μg/ml)	T_{max} (h)	Half-life (h)	AUC_0^6 (μg·h/ml)	AUC_0^∞ (μg·h/ml)
Brain	10	0.4	0.04 ± 0.02[a]	2 – 6	28.3	0.2	0.8
		2	0.11 ± 0.04[a]	2 – 6	22.5	0.5	3.6
		10	0.38 ± 0.12[b*]	2 – 6	NA	1.5	NA
	21	0.4	0.05 ± 0.02[a]	2	28.9	0.2	0.5
		2	0.06 ± 0.03[a]	2	32.6	0.3	3.0
		10	0.25 ± 0.04[b]	4 – 6	NA	1.0	NA
	40	0.4	0.02 ± 0.01[a]	2	NA	0.1	0.2
		2	0.05 ± 0.01[a]	2	23.5	0.2	0.9
		10	0.14 ± 0.07[b]	4	22.9	0.6	2.5
	90	0.4	0.02 ± 0.00[a]	2	NA	ND	NA
		2	0.04 ± 0.01[a]	1	12.5	ND	0.8
		10	0.18 ± 0.02[b]	2	19.5	ND	2.2

C_{max} values are means ± SE. All others are means. n = 3 – 5
NA – Sufficient time-course data not available to estimate parameter due lethality or lack of DLT detection.
ND – Not determined.
C_{max} group means for each age-group with different letters are significantly different from one another at $p \leq 0.05$.
* Significantly different from PND 40 and 90 values at the same dosage ($p \leq 0.05$).
Values for PND 90 rats are from Kim *et al.* (2008).

The age dependent decrease of brain concentrations was clearly attributed to the increasing capacity of metabolism as shown in the following table for hepatic CYP and esterase dependent clearance.

Age- and Pathway-Dependent Intrinsic Clearance

Age (PND)	Liver Weight[a] (g)	Hepatic CYP[b] Vmax (nmol/h) per g liver	Hepatic CYP[b] Km (nmol/ml)	Hepatic CYP[b] Intrinsic Clearance (ml/h)	Hepatic Esterase[b] Vmax (nmol/h) per g liver	Hepatic Esterase[b] Km (nmol/ml)	Hepatic Esterase[b] Intrinsic Clearance (ml/h)	Liver Intrinsic Clearance[c] (ml/h)	Liver Blood Flow[d] (ml/h)	Liver Extraction Ratio[e] (0-1)
10	0.55	185.30	37.79	2.7	23.78	73.69	0.18	2.87	125.6	0.02
21	2.08	381.33	23.40	33.9	114.25	74.76	3.2	37.1	282.9	0.11
40	6.98	1231.73	34.15	224	296.65	118.78	17.4	269.2	588.4	0.21
90	13.6	2611.30	74.90	474	1981.80	172.5	156.3	630.4	1093	0.34

[a] Liver weights were are from Mirfazaelian et al. (2007).
[b] Metabolic rate constants are from Anand et al. (2006a). Intrinsic clearance is computed on a whole liver basis.
[c] Total hepatic intrinsic clearance (Cl_h) is sum of CYP and CaE intrinsic clearance.
[d] Liver blood flows (Q_h) were estimated as a fixed fraction (17%) of cardiac flow (QC) (Delp et al., 1991). The QC (L/h) was based on body weight (kg): 14.1 x $kg^{0.75}$ (Delp et al., 1991). Body weights (g) were 19.6, 57.9, 153.7, and 351, respectively, for PND10, 21, 40, and 90 rats.
[e] Calculated according to Gabrielsson and Weiner (2000).

Scollon et al, 2008 [see KCA 5.7/7 2009/1130987] confirmed that rat hepatic microsomes show mainly oxidative (85%) and to a minor extend hydrolytic (15%) cleavage. In contrast human hepatic microsomes show mainly hydrolytic cleavage of cypermethrin. The enzymes relevant for hepatic metabolism in humans are mainly Carboxylesterase 1 (hCE1) and 2 (hCE2) and only to a minor extent CYP 1A2, 2C8, 2C9 and 3A4.

Already in 2005 Pope et al., [see KCA 5.7/8 2005/1043480] investigated the carboxylesterase activity in 5 infant and 5 adult human liver samples. In this study esterase activity of liver S9 fractions from 4 - 8 month old infants and older ones were comparable to those of 20 years old adult ones whereas samples of younger (2-3 month old) showed definitely lower activity. The relative density of carboxylesterase 1 and 2 in human liver samples was reduced only in the sample of 2 month old infants. All other samples starting from 3 month onwards showed no significant changes to samples of adult ones. While this study is limited by the number of samples investigated, the findings suggest that if maturational expression of liver carboxylesterase contributes to age-related sensitivity of alpha-cypermethrin in humans, it may only be important during very early postnatal maturation. A further study (Yang et al., 2009; Doc ID 2009/1131242) with 104 samples (48 fetal probes, 34 0-10 year old, 22 adult) investigated the age-dependent expression of hCE1 and hCE2 mRNA. The data indicates a significant increase of hCE1 and hCE2 mRNA expression in the first and second months after birth and thereafter a less steep increase up to the age of 10 years. The inter-individual variability of mRNA levels for hCE1 in fetus and child samples was fairly high (218 fold for children and 431 fold for fetuses) whereas for hCE2 it was less variable (21 fold). On protein level the data were given as pooled data for the 0-10 years old and the adult ones, thereby a conclusion on the time point of highest increase on protein level within the group of the very young ones (0-2 years) compared to 6 years and older was not possible. However, it was shown that deltamethrin is 3 times faster hydrolyzed in microsomal preparations from adults compared to 0-10 year old.

Although the mRNA expression level increases mainly within the first weeks after birth and thereby it is likely that the found protein level differences between the group of 0-10 year and >18 year old is mainly due to differences found in the early postnatal phase of the first months this was not adequately shown in this study.
More differentiated investigations are expected within the next time under the aegis of the council for the advancement of pyrethroid human risk assessment (CAPHRA) which has initiated research projects to learn more about factors that may contribute to age-dependent sensitivity to pyrethroids but which are not yet published.

In conclusion, based on the already available literature findings, it is evident that a maturational expression of liver carboxylesterases and CYP P450 enzymes contributes to age-related sensitivity of alpha-cypermethrin in humans and rats. While rats develop their full metabolic capacity within 90 days -humans display a significant increase of metabolic capacity within the first few months of life and a full maturation within childhood. Main source of dietary exposure of infants is milk and supplemental baby food products, which are not considered to cause relevant exposure in humans compared to the significant exposure in the dietary DNT study of zeta-cypermethrin. Further non-dietary exposure via drift, vapour, dermal route and hand to mouth exposure are also not considered to represent a relevant risk based on low vapour pressure / application rate and low ability for locomotion of very young babies.

Therefore the endpoint coming from the dietary DNT study with zeta-cypermethrin is considered relevant for human risk assessment and can be considered as sufficient and realistic case scenario.

Based on the already peer reviewed studies of alpha-cypermethrin, complemented with the DNT study with zeta-cypermethrin and the 90 day dietary study with alpha-cypermethrin, the following EU endpoints are considered relevant.

Neurotoxicity / Delayed neurotoxicity

Effects observed	Toxic for CNS and peripheral motor nerves; neurobehavioral changes are reversible within 3 days following single dose
Acute rat study	NOAEL = 4 mg/kg bw (in corn oil)
4 week oral rat study	NOAEL = 10 mg/kg bw/day (DMSO) **STOT RE 2**
13 week dietary rat study	NOAEL > 36 mg/kg bw/day (dietary)
Developmental neurotoxicity	Maternal and developmental NOAEL: 9 mg/kg bw /day based on reduced bw gain (zeta-cypermethrin) No developmental neurotoxic potential

Remark: Decisions from other authorities: EPA
The generation of a guideline developmental neurotoxicity study with dietary administration of alpha-cypermethrin was clearly not recommended based on the huge database available for pyrethroids as evaluated by the EPA in the Memorandum "Pyrethroids: Evaluation of Data from Developmental Neurotoxicity Studies and consideration of Comparative Sensitivity" [see KCA 5.7/9 2010/1232203]. In this Evaluation, including zeta-cypermethrin and three other Typ II pyrethroids, it was concluded, that guideline DNT studies with dietary administration do not provide useful toxicity data beyond that available from the developmental and reproductive guideline studies, and therefore proposed that future submissions cite currently available data rather than conducting additional DNT studies with pyrethroids. It was concluded that available DNT and reproduction studies do not indicate that juveniles are more susceptible to pyrethroid toxicity compared to adults.
In a second step EPA targeted on study proposals to identify and quantify potential juvenile sensitivity. In the Memorandum "Re-evaluation of the FQPA Safety Factor for Pyrethroid Pesticides" [see KCA 5.7/10 2011/1269851] this was done via PBPK modelling and in-vivo behavioural tests. A comprehensive discussion of the age dependent pharmacodynamic and pharmacokinetic differences of alpha-cypermethrin toxicity was done.
Based on this evaluation EPA used an acute neurotoxicity study generated with cypermethrin and retained a 3X FQPA Factor for children from birth to 6 years of age, whereas all other population groups were considered adequately protected with an FQPA Safety Factor of 1X. It is stated that: "*The enzymes which metabolize and detoxify the pyrethroids are present in rats and humans at birth. As a result, both juveniles and adults are able to tolerate low doses of pyrethroids when the internal dose, or the amount of pyrethroid at the sodium channel, is low. However, the activity of these enzymes increases with age, conveying in adults a greater capacity to detoxify pyrethroids compared to juveniles.*"(EPA, 2011; [see KCA 5.7/10 2011/1269851]

CA 5.7.1 Neurotoxicity studies in rodents

Copy from the Literature data discussed within the ECCO Peer review meeting - Full Report on alpha-cypermethrin [see KCA 5.7/1 AL-901-031, page 164-172 of 222].

Neurodevelopmental toxicity of pyrethroids:

In a first draft of the monographs of cypermethrin and a cypermethrin, the Belgian authorities concluded that both cypermethrin and alphacypermethrin may induce neurodevelopmental effects based on data reported in open literature and more specifically the papers of Cantalamessa et al (1998), which reported an impairment in expression of renal dopaminergic receptors in Wistar rats following gavage at dose of 1 mg/kg bw/d from PND 10 to PND16. Additionally, we cited the papers of Husain et al (1992) which reported delays in the onset of several neurobehavioral parameters in pups following oral (gavage) administration of cypermethrin to female rats at 15 mg/kg bw from GD 5 to GD 21 and finally the paper of Malaviya et al (1993) which reported neurobiochemical changes in brain, including reductions in AchE and Na^+ - ATPase activities in 3 week old rat following gavage treatment of female rats with cypermethrin at 15 mg/kg bw during lactation days 1 to 21.
The applicant gave a critical evaluation of the different studies as well as an additional report of studies from open literature which support the lack of consistency in results obtained from neurobiochemical assays with different pyrethroids, as well as the lack of neurobehavioral correlates to apparent small changes in neurobiochemical parameters. Papers of Eriksson were evaluated.

Summary of the discussion:

Study of Cantalamessa et al: the authors reported a reduced affinity and increased density of dopamine D1-like receptors in kidneys of rats by treatment with cypermethrin (d10-d17 post natal) (1 mg/kg bw/d) suggesting that the compound impairs dopamine DI like receptors mediated function.
According to the authors, these receptors show a developmental pattern similar to that of central dopamine receptors.
Dopamine exerts important renal action, including diuresis, via binding to dopaminergic receptors in the kidney.
Comments from the applicant: in the 3 generation reproduction study with cypermethrin, no clinical signs related to changes in urinary output were noted for animals exposed *in utero* and during lactation period at concentration up to 500 ppm (25 mg/kg bw/d).
Following the termination of one litter interval, animals were 126 days of age and rats were observed in the Cyanamid study at ages comparable to the ages at which changes in dopaminergic receptors were reported in the paper by Cantalamessa et al. It is noteworthy that potential exposure to developing offspring in the 3-generation study with cypermethrin was significantly longer than the 6 day postnatal treatment period in the study by Cantalamessa et al. The absence of any functional correlates (i.e.changes in the volume of urinary output) to the reported changes in dopaminergic receptors in the kidney following postnatal exposure of pups to cypermethrin undermines the biological significance of the data reported by Cantalamessa et al.

Study of Husain et al, 1992: the authors reported that cypermethrin at 15 mg/kg bw/d had morphological developmental effects in rats such as delayed incisor eruption, ear opening, eye opening, primary coat and delayed grip strength.
Comments from the applicant: in this study, it is likely that deliveries were only recorded during a typical 8-hour workday. As such, pups from different litters born on the same day may be considered by laboratory technicians to be one day apart in age, because one litter may have been born in the morning and another litter may have been born in the later part of the evening following the 8-hour working day. Moreover, the day of occurrence of neurobehavioral parameters was likely evaluated only once per day. As such, if a large percentage of control litters was born in the evening, prior to the next 8 hour work day, one could predict that the day of occurrence for a given neurobehavioral parameter for these control litters was recorded as one day earlier than, rather than the same day as, that for litters in cyp treated group born in the morning. Thus, a one-day increase in day of occurrence of neurobehavioral parameters in cyp exposed animals should not be considered treatment related. In another study of Kavlock et al (Journal Environ. Pathol. Toxicol., 2 : 751-765, 1979), no treatment related increases in day of occurrence of neurobehavioral parameters (pups evaluated for survivability, litter size, body weight and day of occurrence of neurobehavioral parameters including startle response, eye opening, righting reflex) were observed for pups following exposure of dams to decamethrin, another type H pyrethroid, at 2.5 or 5 mg/kg bw/d from gestation day 7 to lactation day 15, an exposure period substantially longer than that utilised by Husain et al.

The study reported by Malaviya et at (1993) suggest that disturbances in dopaminergic and cholinergic pathways may lead to a functional delay in brain maturation after cypermethrin or fenvalerate. Effect on neurotransmitter receptors was examined by In utero exposure to cypermethrin at 15 mg/kg , or fenvalerate at 10 mg/kg bw from day 5 of gestation until day 21.Fenvalerate decreases significantly H^3 spiroperidol or 3H QNB binding to striatal brain membranes in pups and cypermethrin was without effect. An increase of 3H —QNB binding and spiroperidol binding was observed in pups exposed to Fv or Cyp during the lactation period (15 mg/kg cyp day 1 Post natal to 3 week).

These effects suggest, according to the authors, a delayed maturation of cerebral cortex.

Comments from the applicant: it is unlikely that cypermethrin would elicit no changes in enzyme activity in the brain of 3 week old rats following gestation exposure, while a second type II pyrethroid, fenvalerate would increase or decrease enzyme activities following the same pattern of exposure. Changes (increases or decreases) in receptor binding noted for cyp or fenv appear dependent on the period of exposure to either pyrethroid and it is unlikely that these changes in receptor binding are biologically significant. The ligand used (H-QNB) is a non-selective ligand because it does not distinguish between various subtypes of muscarinic receptors. As five different subtypes of muscarinic receptors have been identified and selective radioligands are available for several subtypes, these results should be interpreted with caution. Finally, it is unlikely that modulation of muscarinic receptor binding is relevant or causal endpoint for potential pyrethroid induced neurotoxicity. Because Ac binds to muscarinic receptors, changes in muscarinic receptor binding of acetylcholine may be a more relevant endpoint for cholinesterase inhibitor induced neurotoxicity.
Results from the 3 generation reproduction study with cypermethrin indicate no neurobehavioral effects (clinical signs of neurotoxicity) for animals which had been exposed to cyp in utero and during the lactation period at dietary cc up to 500 ppm. However, at 500 ppm (25 mg/kg bw/d), a statistically significant reduction in parental bw for all generations during the premating treatment period were observed. Animals were likely evaluated for clinical signs of toxicity from approx. 3 weeks of age, the age at which changes in enzyme activity and /or receptor binding were reported in the study of Malaviya et al. As such, the slight changes in enzyme activity and receptor binding in the brain following gestation or lactation exposure to cypermethrin do not appear to be correlated with any neurobehavioral finding.

Results from additional studies with pyrethroids:
Paper of Eriksson and Fredriksson (toxicology and applied pharmacol, 1991, 108, 78-85): the authors reported a decrease in the density of muscarinic receptors in the brain of the adult NMRI mice and an increase in motor activity in these mice following following gavage of pups with either 0.7 mg/ kg bw/d bioallethrin (type I) or 0.7 mg/kg bw/d of deltamethrin (type II) administered in a fat emulsion vehicle from PND 10 to PND 16.
In an attempt to repeat these findings, Muhammad and Ray (study in addendum) conducted a study in which bioallethrin and delatmethrin was administered to neonatal NMRI mice from PND 10 to 16. The test material was administered by gavage as a fat emulsion at 0.7 or 3.5 mg/kg bw/d for bioallethrin and 0.7-mg/kg bw/d for deltamethrin. Muscarinic receptor binding and motor activity were evaluated in 4-month mice. Results from this study showed changes in muscarinic receptor density in adult mice, which had received bioallethrin during the postnatal period. However, these changes were small, inconsistent across 3 trials (increase in one and similar to controls in the 2 other), and not clearly dose related. For animals which had received deltamethrin during postnatal period, muscarinic receptors density at 4 months of age was significantly decreased in one trial, but not in another trial, when compared to controls. Adult animals, which had been exposed to either bioallethrin or deltamethrin during postnatal period, exhibited minimal changes in motor activity in some experiments but not in other experiments. Moreover, the behavioural results for mice that had been exposed to bioallethrin were not dose-related.

The collective results from the paper by Muhammad and Ray show that neurobiochemical and neurobehavioral findings are not reproducible for the same pyrethroid in different experiments conducted at the same laboratory. Moreover, the neurobiochemical findings reported were inconsistent for the two pyrethroids tested (i.e. increased muscarinic receptor binding density in one trial for bioallethrin and decreased muscarinic receptor density in one trial for deltamethrin). Further, the increase in muscarinic receptor density observed by Muhammad and Ray in one trial following exposure of postnatal mice to bioallethrin was in opposition to that observed by Eriksson and

Fredriksson (i.e. decreased muscarinic receptor density) following exposure of postnatal mice to this identical pyrethroid.

The lack of consistent and reproducible findings from the muscarinic receptor binding assay (i.e. density determinations) reported by Eriksson end Fredriksson and Muhammad and Ray suggest that small changes in neurobiochemical parameters are likely not related to treatment with pyrethroids, as these changes were **not sufficiently robust to survive minor intra- and inter-laboratory variations** in experimental conditions. Even if exposure to pyrethroids did result in small changes in neurobiochemical parameters i.e. receptor densities, these changes would be expected to have little functional consequence given the rather large receptor reserve capacity of the brain. In fact, correlation's between changes in muscarinic receptor density and changes in motor activity reported by Eriksson and Frederiksson were **not confirmed** in the experiments conducted by Muhammad and Ray.
Results from inhalation studies conducted by Bayer AG with several pyrethroids support the lack of correlation between changes in muscarinic receptor density and neurobehavioral findings following postnatal exposure to pyrethroids. In these studies, neonatal NMRI mice were administered one of five different pyrethroids via inhalation exposure (6 hours/day) from PND 10 through 16, and animals were evaluated for spontaneous motor activity and muscarinic receptor density at both 17 days and 4 months of age. Data from these studies showed that for the majority of compounds tested, slight increase in muscarinic receptor density were noted for mice on PND 17 with no correlating changes in spontaneous motor activity for these animals. As no consistent neurobehavioral changes could be correlated with the subtle, inconsistent and non-reproducible neurobiochemical changes reported, the neurobiochemical changes, even if treatment related, are likely not biologically significant.
Importantly, results from inhalation studies by Bayer AG showed no changes in muscarinic receptor density or spontaneous motor activity in adult (4 month old) mice for the majority of pyrethroids following postnatal inhalation exposure. These data from adult (4 month old) mice further refute the findings by Eriksson and Fredriksson.
The data reported by Bayer AG are noteworthy as the inhalation route of exposure can be considered as worst-case route of exposure compared to the oral route. This is because the inhalation route of exposure bypasses the first-pass effect of the liver (i.e. detoxification) and generally results in complete (i.e. 100%) absorption of a chemical into the systemic circulation.
The detailed analyses of neurobehavioral findings and biochemical changes in the brain and kidney, as presented in the above sections, indicate that prenatal and post natal exposure to pyrethroids does not result in any significant changes in neurotransmitter release or receptor number in the brain or kidney which can be correlated with adverse effects on neurobehavioral or physiological function. Based on the lack of conclusive (i.e. reproducible and consistent) evidence from the open literature, which suggests that pyrethroids are developmental neurotoxicants, a developmental neurotoxicity study with alphacypermethrin is not scientifically justified.

Additional support which negates the requirement for a developmental study with alphacypermethrin:

An evaluation of the collective results from the developmental toxicity studies with alphacypermethrin and the developmental and the 3-generation reproduction studies with cypermethrin also negates the requirement for a developmental neurotoxicity study with alphacypermethrin. Results from the developmental toxicity study in Sprague-Dawley rats with alphacypermethrin technical support a NOAEL for maternal toxicity of 9 mg/kg bw/d, based on clinical signs of neurotoxicity, decreased food consumption, and a weight gain reduction of 22% for dams during the treatment period (gestation day 6 to 15) at 15/18 mg/kg bw/d, the highest dose tested. The NOEL for developmental toxicity in this study was also 9-mg/kg bw/d, based on decreased foetal weights at 15/18-mg/kg bw/d.

In New Zealand rabbits with alphacypermethrin a NOAEL for maternal toxicity of 15 mg/kg bw/d is based on reductions in food consumption and body weight loss of 0.03 kg during treatment period (gestation day 7 to 19) at 30 mg/kg bw /d, the highest dose tested.
Results from the developmental toxicity study in Sprague Dawley rats with cypermethrin support a NOEL for maternal toxicity of 17.5 mg/kg bw/d, based on a 12% reduction in body weight gain during the treatment period (gestation day 6 to 15) at 35 mg/kg bw/d, the next highest dose tested. Results from developmental toxicity study with rabbits with cypermethrin support NOELs for maternal and developmental toxicity of 120-mg/kg bw/d, the highest tested dose.
Lastly, results from the 3 —generation reproduction study with cypermethrin in Wistar rats support NOELs for parental and offspring toxicity of 100 ppm (5 mg/kg bw/d), based on reductions in food consumption and mean body weights during the premating treatment periods for all parental

generations and reduced mean pup weights on PND 21 for F3B males at 500 ppm, the highest tested dose.

The results from these studies demonstrate that neither alphacyp nor cyp is a selective developmental toxicant or a teratogenic agent in either the rat or rabbit. Because neither alphacyp nor cyp is selectively toxicant to the developing fetus or offspring, there is no increased sensitivity of developing offspring following prenatal or postnatal exposure to alphacyp or cyp. In the absence of any selectivity or increased sensitivity to the developing fetus or offspring, a developmental neurotoxicity study with alphacyp is not warranted.

A pyrethroid ad hoc working group sponsored by Industrieverband Agra e. V. developed a white paper which discussed the potential neurotoxicity of pyrethroids to developing animals. This paper was submitted to the German regulatory authorities (BBA/BGA) in June 1994. A retrospective of the multigenerational and developmental toxicity studies conducted with many different pyrethroid insecticides was included in this paper. Results from this analysis support the conclusions drawn from the developmental toxicity and reproductive toxicity with alphacyp and cyp, namely, that neither pyrethroid is selectively toxic to developing offspring. A summary of the results from reproductive toxicity studies with numerous pyrethroids, including deltamethrin and zetacypermethrin, is included (table 1), appendix C and a summary of the results is included in table (2) appendix C. Finally a comparison of the results from the rat reproductive toxicity and rat developmental toxicity studies conducted with these pyrethroids is included in table 3 of appendix C

The results presented in table 1 of appendix C show that the majority of NOELs for offspring's toxicity are equal or higher than the NOELs for parental toxicity. Moreover, results from the majority of these studies show no functional or morphological changes in the nervous system of offspring. Although the multigenerational studies were not specifically designed to assess potential peri- or postnatal neurotoxicity following pyrethroids, these studies can, in fact, be used to identify any potential effects on the developing nervous system. Specifically, if pyrethroids were developmental neurotoxicants, pups exposed to pyrethroids in utero and during lactation would be expected to show impairment of physical development and growth and maturation, as well as inadequate nestbuilding (for rearing of subsequent generations) and lactation. In fact ad hoc working group reported that rearing and nursing behaviour of dams from all parental generations, as well as social and suckling behaviour of neonates, were not affected by treatment and, except in cases where clearly toxic (i.e. sublethal) dose were tested, there were no disturbances in the physical development of offspring during lactation and post-weaning periods.

In table 2, the NOELs for embryotoxicity are generally equal to or higher than the NOELs for maternal toxicity for both rats and rabbits. These results presented in table 3 show that for nearly all pyrethroids, the NOEL for toxicity to offspring from reproduction study in rats is of similar order of magnitude as the NOEL for developmental toxicity from the rat developmental toxicity study. These data indicate that there is no enhanced toxicity to developing offspring following an extended exposure period (including exposure during postnatal development) as well as an evaluation of additional endpoints of potential offspring toxicity, in the multigenerational reproduction studies conducted with pyrethroids.

Taken together, the retrospective analysis presented in the white paper prepared by the pyrethroid ad hoc working group provides strong evidence that treatment of lactating and/or pregnant females with pyrethroids is not associated with developmental neurotoxicity.

Our evaluation:

Age-dependent differences in susceptibility to pyrethroid insecticides (Sheets, L. (Neurotoxicology, 21(1-2): 57-64, 2000).

The effect of pyrethroids on the startle response in 21-day-old animals (Long-Evans rats)was compared with effects in adult rats of same strain. The study was performed in the same lab. and results are summarised in table 1. The results indicate that there are no differences between pups and adults in startle response.

In this study a difference between pups and adults was seen: higher doses selected for startle responses generally evoked clinical signs in pups and not in adults. This age-dependent difference in response led to determinations of the LD50 for pups and adults. (Table 2) Differences were seen for deltamethrin and cypermethrin and for 21 day old rats, the LD50 was approximately 7 fold lower than for the adult with both Type II pyrethroids.

Deltamethrin was used as a model type II pyrethroid to investigate target tissue brain levels and cc of deltamethrin was measured in whole brain, the presumed target tissue under the circumstances that reduce the startle response by approximately 50% (2 h after 4 mg/kg bw):

The results showed that brain level adult deltamethrin conc. were << than brain level in weaning.

At the respective LD50 dose, the same brain level is observed in adults and weaning rats, which received a seven time lower dose.
The main age related differences that the applied dose associated with a lethal brain cc is much lower in pups than in adults and this difference only occur at high dose levels that exceed the neonate's capacity for detoxification. This difference seems to be specific for type II pyrethroids and is consistent with metabolism as basis for the difference since these compounds contain alpha cyano moiety that slow down their degradation to less toxic metabolites.

In conclusion, neonates are more sensitive than adults to acute lethal dose of certain pyrethroids but not to the much lower levels that are relevant for dietary risk assessment. Target sites in the brain of the neonates are not inherently more sensitive than in the adult over a wide range of exposure. These results indicate that susceptibility of neonates is associated with the neonate's relatively limited metabolic capacity for detoxification.

Table 1.

	control	Low dose	Middle dose	High dose
		% increase or decrease in response amplitude relative to control values		
Cismethrin	50±2	0 (3 mg/kg bw)	-16(6 mg/kg bw)	-24(12 mg/kg bw)
In adults		2 to 3 fold increase in startle response is observed at 6 or 12 mg/kg bw.		
Permethrin	38+4	+5 (30 mg/kg bw) no effect	+65 (60 mg/kg bw)	+22 (120 mg/kg bw)
In adults			in adult also increase 2-fold	in adult also increase 2-fold
Deltamethrin	58+6	-20* (1 mg/kg)	-39*(2 mg/kg)	-59*(4 mg/kg)
In adults		Decrease in response amplitude of 50% at 4 mg/kg		
cypermethrin	41±5	-40* (9 mg/kg)	-45*(19 mg/kg)	-55*(38 mg/kg)
In adults		Decrease in response amplitude of 50% at 38 mg/kg		

*P<0.05

Table 2. Lethality in neonatal, weaning and adult male rats

	PND11	PND21	PND72

Brain level at 4 mg/kg		0.052 tig/g brain	0.023 pg/g brain
Brain level after lethal dose		0.129 Rig after lethal dose of 12 mg/kg bw	0.145 tig/g after lethal dose of 80 mg/kg bw
cypermethrin	18	73	439

Neurobiology, Gomeza et al, PNAS, 1999, **96, 10483-10488.**

Coordinated locomotor activity depends on the proper balance of muscarinic cholinergic and dopaminergic neurotransmission in the **striatum.** The M4 muscarinic receptor is expressed abundantly in the striatum. **M4 receptor** deficient M4 -/- mutant mice showed a significant increase in basal **locomotor activity** (by about 30% as compared with their wild type littermates) as measured by the total number of consecutive photobeam interruptions during a 60-min test period. M4 receptor **KO** mice were more active than their wild type. The M4 receptor subtype is colocalised with D1 and D2 dopamine receptors on striatal projection neurons. D1 receptor —mediated increases in locomotor activity are potentiated in the absence of functional M4 receptors. In mice, **M2** receptor stimulation is primarily responsible for muscarinic receptor dependant **analgesia.** Muscarinic receptor mediated **salivation, tremor, and hypothermia** responses are dependent of **M3** subtype receptor. **M1** receptors may play a role in higher cognitive functions such as **memory and learning.** Antagonists that display high affinity for MI receptors also show high affinity for M4 receptors. Members of the muscarinic acetylcholine receptor family(M I -M5)are widely expressed in the central nervous system and in body

periphery. Central muscarinic receptors are known to play key roles in memory and learning as well as in the regulation of many sensory, motor and autonomic processes. In the periphery, muscarinic receptors mediate the well known activities of acetylcholine released from parasympathetic nerves. The precise functional role of the individual muscarinic receptor species remain to be determined.
At the molecular level, the M4 subtype is expressed abundantly in the striatum (caudate-putamen) and are also present, though at lower levels, in several other brain regions including cerebral cortex and hippocampus. In the striatum, a region known to be critically involved in extrapyramidal motor control, the M4 as well as other muscarinic receptor subtypes are coexpressed with D1 and D2 dopamine receptors on striatal projection neurons. Considerable evidence suggests that complex interactions between these two neurotransmitter receptor systems are critical for the proper regulation of motor control.. in M4 receptor deficient mice an increase in basal locomotor activity and hypersensitivity to stimulatory locomotor effects of D1 receptor activation were observed, indicative of functional interaction between these two receptor systems.3 H QNB is a non selective muscarinic antagonist which labels all five muscarinic receptor subtypes. Olfactory bulb contains also high levels of QNB labeled receptors, comparable to striatum

Eriksson and Fredriksson, toxicol and applied pharmacol., 108, 78-85,1991.

Spontaneous behavior was tested in male mice at the age of 17 days and 4 months : motor activity, locomotion, rearing were measured. Receptor assay was performed in cerebral cortex, hippocamus and striatum measuring receptor density using 3H QNB as antagonist for labeling of all muscarinic receptors.
Results: neonatal exposure to bioallethrin or deltamethrin between day 10 and day 16 postnatal day produces significant behavioral deviations in the adult mouse at 4 months about 1 week after behavioral tests on 4 month mice, they were killed and MAChR were assayed in Ccortex, hippocampus and striatum. There was a significant decrease and tendency toward decrease in the amount of 3H QNB binding sites in cerebral cortex of mice receiving bioallethrin (0.7 mg)and deltamethrin (0.7 mg, at 10 days for 7 days)respectively. In the other brain regions, hippocampus and striatum, no significant changes were observed.

	Densities of muscarinic receptors in adult mouse		
	cortex	hippocampus	striatum
Control	1266 ±82	1332±134	1539±91
Bioallethrin	1132±188*	1377±108	1477±127
deltamethrin	1204±88*	1354±76	1546±122

Recently, the authors reported that neonatal exposure to bioallethrin and deltamethrin, administered in the same manner and at the same doses as in the present study, affected the MAChR in the 17 day old mouse. The bioallethrin exposure caused an increase in the density of MAChR in cerebral cortex and an increase and decrease in proportion of binding sites. Deltamethrin treatment also caused an increase in the density of MAChR, but the proportions of HA and LA binding sites were reversed.

Densities of muscarinic receptors in cerebral cortex and hippocamus of neonatal mice

		Deltamethrin mg/kg bw Type II		Bioallethrin mg/kg bw Type I	
	control	0.71	1.2 clinical signs	0.71	72 clinical signs
Cortex	805±60	869±78*	815±48	875±47*	801±66
Hippocampus	923±110	890±73	854±51*	875±77	907±65

(toxicol. Applied Pharmacol, 102, 456-463)

Malaviya et al, 1993: pregnant rats were given 15 mg/kg bw cypermethrin daily from day 5 until day 21 of gestation. Synaptosomal membranes were prepared from corpus striatum. Binding was assayed with spiroperidol or QNB. No clinical signs were noted. QNB binding was markedly *decreased* ; no significant changes in binding in spiroperidol to striatal membranes in 4 week of age pups exposed during gestation day 5-21.
Another group was exposed during lactation from day 1 to 3 week to 15 mg/kg bw cypermethrin. ^{3}H QNB binding to striatal membranes was statistically significantly *increased.* Spiroperidol binding was not modified.

In the developing rat brain, mAChRs appear between gestational day 16 and 18. Their density increases gradually after birth, reaching adult levels at approximately 30-45 days of age. MeHg which increases mAChR density (up-regulation) in adult rat brain (hippocampus and cerebellum) decreased temporaly binding in the immature rat brain. MeHg inhibits development of mAChRs when administered before they appear (Coccini et al, environ.health perspect. 108, 2000, 29-33).

Our conclusion: coordinated locomotor activity depends on the proper balance of muscarinic cholinergic and dopaminergic neurotransmission in the striatum. M4 receptor subtype is particularly abundant in the striatum and receptor deficient M4 -/- mutant mice showed a significant increase in basal locomotor activity, It is *likely* that increased locomotor responses are a result of altered striatal activity.
In the paper of Eriksson, a slight decrease (statistically significant ?) is observed in the cortex. Therefore, a correlation between locomotor activity modification and decrease in receptor density in striatum is not established.
In the paper of Malaviya, exposure to cypermethrin at 15 mg/kg bw/d during gestation, 3H QNB binding is decreased and during lactation, 3H QNB binding is increased. The results reported with fenvalerate are not in the same direction. (!)
Based on this study, the NOAEL is < or = 15 mg/kg bw/d .
In the 3 generation rat study, the NOAEL = 10 mg/kg bw/d.

Vulnerable periods during ontogenesis of CNS can be divided into 2 major courses of events :

1. early brain development : brain aquires its general adult shape and precursors of glial cells and neurons proliferate.
2. Brain growth spurt : rapid fundamental changes including maturation of axonal and dendritic outgrowth; establishment of neural connections; synaptogenesis, cell, axon and dendrite death proliferation of glial cells with accompanying myelinization = cytoarchitectural changes are accompanied by a vast number of biochemical changes. Fetal-neonatal brain -+ mature adult. Stage of development when animal acquire many new motor and sensory faculties and spontaneous motor behavior. In adult animal, induction of behavioral and cholinergic disturbances is limited to a short period namely around post natal day 10.

In human, BGS occurs maximally at the 3rd trimester of pregnancy up to 2 years of life. In mouse and rat: this period is neonatal spanning the first 3-4 week of life.
Early postnatal exposure in the rodent encompasses a time span equivalent to peri-neonatal exposure in the human. Therefore, by administering substances to mice during the 10-16 postnatal day period, there will be a situation, which is not identical to that in humans but still involves a sensitive period of postnatal life. Although the rodent seems to be an appropriate model for testing the postnatal neurotoxic effects of pyrethroids to make extrapolations to human, the use of only one single mouse strain gives a rather narrow view.
In order to affect brain receptors, the compound must in a first time reach brain ; no specifically high level of radioactivity was observed in rat brains. It should be important to know if cypermethrin accumulates in brain and more specifically in a particular brain region (cortex ?)
Adaptative changes involving mACHrs in target organ may occur after prolonged overexposure and neurotransmitter receptors are regulated by homeostatic mechanisms that compensate for changes in the amopunt of agonist or antagonist to which they are exposed. For example, although mAChRs overstimulation induces a receptor density decrease (down-regulation), prolonged treatment with muscarinic antagonists cause receptor increase and supersensitivity to muscarinic agonists. It is increasingly evident that adaptation of neurotransmitter receptors may be a primary mechanism mediating the long term actions of drugs and chemicals in the CNS. In the developing rat brain, mAChRs appear between gestation day 16 and 18. Their density increases gradually after birth, reaching adult levels at 30-45 days of age. It seems however that the postulated up regulation mechanism which in the adult compensates for the complex interactions of compounds with cholinergic system is not functional in the immature brain. (Coccini et al, 2000).

Which kind of animal study should be designed to gain more information relevant for clarifying the mechanisms of action and the endpoints for determining a dose effect relationship ?

End of Copy from the Literature data discussed within the ECCO Peer review meeting report
Alpha-cypermethrin, hens, route not given, 0, 70, 140 and 700 mg/kg bw. Reversibility after 700 mg/kg bw ([redacted] 989c) (Dossier Gharda)

Guidelines:	Partly in compliance with the test method OECD 418 (1984)
Deviations:	Test should include a positive control group and a concurrent control group of animals. Route of administration is not given. Statistics were not performed. Absence of complete raw data.
GLP:	No
Acceptance:	not stated

5 Young adult female domestic white leghorn hens received a single dose alpha-cypermethrin (99.0%) at 0, 70, 140 and 700 mg/kg bw /d in DMSO. One group exposed to 700 mg/kg bw was observed for reversibility of toxic effects.
Findings: no effect was seen on behavior (no ataxia developed), food consumption or body weight. Histopathology revealed a dose-related pattern of effects on brain, spinal cord, and sciatic nerve. Inflammatory reaction in the brain accompanied with astrocytic proliferation (140 mg/kg bw) or vacuolated neuron cells with astrocytic activation, slight changes in certain fields, and edema (700 mg/kg bw).
Conclusion: At high doses, alpha-cypermethrin is toxic for the CNS and peripheral motor nerves. The NOAEL for neurotoxicity under the conditions of this study was <70 mg/kg bw.

Alphacypermethrin, rat. oral by gavage 0, 4, 20 and 40 mg/kg bw (1993b, see CA 5/13 AL-451-004) (Dossier Cyanamid)

Guidelines:	The study was performed according to the EPA Pesticide guideline subdivision F. Addendum 10. Neurooxicity Series (1991) and is therefore not in compliance with OECD guideline 418 (1984)
Deviations:	Hens must be used and observed during 21 days. There is no positive control.
GLP:	Yes
Acceptance:	The study was recommended to be used for acute reference dose setting.

10 Charles River (Crl:CD:BR)rats /sex/dose received by gavage a single dose alpha-cypermethrin(ST91/243) at 0, 4, 0, and 40 mg/kg bw/d in corn oil. Animals were observed 14 days following treatment.
Findings: In the range-finding study for the acute neurotoxicity study in rats deaths were observed at 50 and 60 mg/kg bw. Profound signs of neurotoxicity were observed at 40, 50, and 60 mg/kg bw. In the main study each one animal died in the 20 and 40 mg/kg bw dose groups. Effects observed included severe clinical and neurobehavioural changes shortly after dosing. Most changes were completely reversed by 3 days after dosing in the surviving animals. The only histopathological finding showing a relationship to treatment was sporadic fibre degeneration in the sciatic nerve, which occurred in the control and dose groups, but with an incidence that was statistically significant at 20 and 40 mg/kg bw only. Fore and hind limb gripstrength, hind limb landing footsplay, motor activities were not affected.

Table B.5.7.1-1 : Neurotoxic effects of alpha-cypermethrin: FOB conducted 5 hours post-dosing observations showing overall statistical significant difference.

Endpoint/dose	0	4 mg/kg bw/d		20 mg/kg bw/d		40 mg/kg bw/d	
		♂	♀	♂	♀	♂	♀

Table B.5.7.1-2 : Occurrence of fibre degeneration in proximal and distal sciatic nerves of rats dosed with alpha-cypermethrin (number affected animals/number examined)

Fibre degeneration in sciatic nerve			4 mg/kg bw/d		20 mg/kg bw/d		40 mg/kg bw/d	
	♂	♀	♂	♀	♂	♀	♂	♀
proximal :	0/5	0/5	0/5	0/5	5/5	4/5	5/5	0/5
distal:	0/5	0/5	0/5	0/5	2/5	0/5	3/5	0/5
proximal or distal:	0/5	0/5	0/5	0/5	5/5	4/5	5/5	0/5

Conclusion: At high doses alpha-cypermethrin is toxic for the CNS and peripheral motor nerves, but does not produce signs similar to the OP-induced delayed neuropathy. A single oral dose of 4 mg/kg bw (NOAEL) did not cause neurotoxicity. The NOAEL is 4 mg/kg bw.

Remark from BASF: Below is the supplemental study which was discussed in the DAR of alpha-cypermethrin (1999) in chapter 5.8.2.1. Based on placing this study in the list of endpoints in the EFSA conclusion (2004) under the point "Neurotoxicity study" it is shifted to this chapter with the hope to support clarity.

- Rat, oral administration by gavage:
-Phase I: 10 doses (37.5 mgtkg) + 10 doses (25 mg/kg), 4 weeks
-Phase II: 10, 20,40 mg/kg, 4 weeks (1983, AL-451-002)
(Dossier Cyanamid)

Guidelines: MOA-study, no guideline
GLP: No
Acceptance: The study was accepted

Phase I: 40 Wistar rats/sex/group received alpha-cypermethrin (b.n.°7; 96.6%) in DMSO by intubation. 1 dose per day, 5 day /week for 2weeks (37.5 rng/kg bw) and in arachis oil for 2 weeks (25 mg/kg bw). Control rats received DMSO for 2 weeks (l0 doses) fofollowed by a further 10 doses of arachis oil.
Phase II: 10 Wistar female rats /roup received 20 doses of alpha-cypermethrin (b.n.° 7; 96.6%) in DMSO by intubation over a 4 week period (5 dav/week) at 10, 20 or 40 mg/kg bw.

In Phase I over 80% of the treated animals ahowed some signs of intoxication . 21% of the treated animals died. Signs of intoxication were abnormal gait, ataxia, piloerecion, lethargy, chromodacryorrhoea, salivation and hypersensitivity to sensory stimuli. The glucuronidase and beta-galactosidase activities in the sciatic posterior tibial nerve (SPTN) were increased at 5.6 and 8 weeks after commencement of dosing, elevated maximal at week 5 and had recovered by the end of the 12 week study. No significant enzyme changes were found in the trigeminal ganglia and trigeminal nerve.
In Phase II signs of intoxication were similar to those reported in Phase I at 20 and 40 mg/kg bw. No signs of intoxication were at 10 mg/kg bw and enzyme activity was also not different from control. Dose dependent enzyme changes in the SPTN and in the trigeminal ganglia and nerve were seen in the 20 and 40 mg/kg bw group.
Conclusion: Biochemical changes consistent with sparse axonal degeneration were found in the SPTN of rats which had received 20 doses of alpha-cypermethrin at 40 mg/kg bw . At 20 mg/kg bw no consistent biochemical changes were found in the SPTN of animals. The enzyme changes in the trigeminal nerve and ganglia were smaller than in the SPTN, would therefore, not be expected to be related to any patholgical change.
The NOAEL = 10 mg/kg bw;

Taken from the DAR of Zeta-cypermethrin:

Report: CA 5.7.1/1
Anonymous, 2006a
Draft Assessment Report (DAR) Zeta-Cypermethrin - Volume 1 to volume 3 - Initial risk assessment provided by the RMS Belgium of the third stage (part A) of the review programme referred to in article 8(2) of council directive 91/414/EEC
2006/7013990
Guidelines: none
GLP: no

Development neurotoxicity study of zetacypermethrin in rats [redacted] 2005)

Page 6-80 to -84

Remark: **This already peer-reviewed and on European level accepted study is considered accurate to address the request for DNT investigations with alpha-cypermethrin based on the bridging rationale presented in CA 5.00.** An additional conversion factor is not considered necessary. Based on the proven lactational transfer of zeta-cypermethrin within this study and via the study presented under CA 5.8.2/5 the demand for direct pup dosing with any cypermethrin in general is not justified according to the OECD Guideline for the Testing of Chemicals No. 426. In paragraph 21 it is stated that direct dosing of pups should be considered in those cases where there is a lack of evidence of continued exposure to offspring. Continuous exposure is definitely shown for zeta-cypermethrin, it is supported by data generated with beta-cypermethrin (see DAR beta-cyperemehrin, multigenerationstudy) and transfer into milk was shown for alpha-cypermethrin in goat and cow (see chapter CA 6.2.3) and is indicated in the DNT study with alpha-cypermethrin (see CA 5.7.1/3). Based on this study it is concluded that lactational exposure to zeta-cypermethrin does not occur at sufficient quantities to induce adverse effects in pups up to maternal toxic doses. Based on the bridging approach this is considered valid for alpha-cypermethrin as well.

Development neurotoxicity study of zetacypermethrin in rats [redacted] 2005)

Executive Summary

Neurotoxicity of zetacypermethrin in rats was evaluated in a developmental neurotoxicity study. 25 female rats per group were exposed to zetacypermethrin from gestation day 6 through lactation day 21 at dietary concentrations of 50, 125, 300 ppm. On PND 4, surplus pups were selected for culling and litters were standardized to 20 pups/litter.
No mortality and no abnormalities at necropsy were observed in the maternal rats and the offspring. Body weight, body weight gain, and food consumption were reduced in the F0 females of the 300 ppm group at various time points. Mean body weight for F1 male and female offspring in the 300 ppm group were lowered. No effects were seen on F1 age of attainment of balanopreputial separation or vaginal patency or on mean bw at the age of attainment. Occasional statistically significant differences were obtained in some offspring behavioral parameters and in one of 32 brain morphometric measurements, these apparent alterations did not occur to a degree or in a manner suggesting a compound-related pattern of neurotoxicity. In conclusion, a NOAEL for maternal and developmental toxicity was set at 125 ppm considering the decreased body weight, body weight changes and food consumption in dams and decreased body weight and body weight changes in litters.

I. MATERIAL AND METHODS

A. MATERIALS

1 Test Material:

B. STUDY DESIGN AND METHODS

Range-finding study:
10 females rats per group received zeta-cypermethrin at dietary concentrations of 0, 50, 80, 300, 350 ppm on gestation day 6 through lactation day 21. On PND 4, surplus pups were selected for culling and litters were standardized to 8 pups/litter. All F1 pups were observed daily and motor activity was assessed for 1 pup/sex/litter on PND 21. Milk samples were collected on LD 4, 11 and 17/18 and the same dams were used for blood collection on LD 5 and 21. The culled pups from the same five dams were utilized for blood collection on PND 5. Quantification of zetacypermthrin in plasma was performed with GC/μECD. The remaining F0 females were euthanized and necropsied on LD 21. A storage stability study has shown that cypermethrin was stable in milk and liver for at least 3 months under frozen conditions. Rat milk and plasma samples were analyzed within 30 days of receipt.

25 female rats per group were exposed to zetacypermethrin from gestation day 6 through lactation day 21 at dietary concentrations of 50, 125, 300 ppm. On PND 4, surplus pups were selected for culling and litters were standardized to 20 pups/litter. Homogeneity and stability of zetacypermethrin in diet was demonstrated. The study was perfomed under GLP (no attest of competent authority) and in compliance with OECD guideline 426 (adopted 2003).

II. RESULTS AND DISCUSSION

A MATERNAL OBSERVATIONS

Range-finding study:

No clinical signs were observed at any dose. Lower mean lactation bw and bw gain was observed at 300 and 350 ppm.
Body weight: in the 350 ppm group were slightly reduced throughout gestation period, without affecting statistically the mean gestation body weight.
Food consumption was decreased at 350 ppm during gestation. Lower mean food consumption was observed during lactation at 300 and 350 ppm.
No compound-related effects were seen on mean number of pups born, former implantation sites and unaccounted sites. Mean live F1 litter size, % male at birth, postnatal survival and general physical condition of pups were unaffected.
Main study:

Mortality: all F0 treated females survived until the scheduled necropsies.
Body weight and body weight gain in F0 females were lowered at 300 ppm beginning late in gestation and continuing through lactation day 21.
Food consumption: was reduced for F0 females at 300 ppm during the first three days of treatment and throughout lactation period.
Necropsy: no abnormalities were seen in F0 females.

B LITTER DATA

Range-finding study:

Mean male and female pup body weight gains in the 350 ppm group were lower during preweaning, and post weaning.
There was a decreasing trend in motor activity patterns (total activity and/or ambulatory activity counts) in all exposed males and females on PND 21.

Main study:
No compound-related effects were seen on mean number of offspring born, live litter size or % males /litter at birth. Offspring survival throughout the postnatal period was unaffected by the compound. Mean body weight for F1 male and female offspring in the 300 ppm group were lowered. No effects were seen on F1 age of attainment of balanopreputial separation or vaginal patency or on mean bw at the age of attainment. No effects were seen at necropsy.

FOB:
No consistent dose-related trends were noted when components of the FOB were evaluated on PND 4, 11, 22, 45 and 60. Forelimb grip strength value for males at 300 ppm was lower on PND 22. They were however within the historical control data of the company (174.8±35; 146.8±30.86; 109±35, control; 300 ppm and historical control respectively). Such an observation was not seen at subsequent intervals and there were no indications of neuromuscular deficits in other aspects of FOB assessments or in other behavioral tests. A higher number of females from the 50 ppm group were observed with eyelids wide open on PND 22, and lower urination counts were noted for males from the 50 and 125 ppm groups on PND 45. These isolated findings were not considered treatment related as no effects were recorded at top dose.

Motor activity:
On PND 17, significant treatment group by time interactions were found for both ambulatory and total activity counts in animals of both sexes. In males at 300 ppm, significantly higher levels compared to control values were noted only during the fourth session interval (45-60 minutes) in both measures of activity. For females on PND 17, significantly lower levels of activity were noted during the first interval (0-15 min) in rats of the 300 ppm group and during the second interval (16-30 min) in offffsprings from 125 and 300 ppm. Statistically significantly mean overall lower ambulatory and total activity counts were noted in females from the 300 ppm group on PND21. Apparent decrease in motor activity in females on PND 21 were considered more likely due to a slight shift in the timing on the normal inverted U-shaped developmental activity pattern, than to the zetacypermethrin effect of maternal and/or direct offspring consumption during pre-weaning period.

On PND 61, there were no changes in ambulatory or total activity counts that were considered biologically meaningful. No statistically significantly effects were seen in females. In males, an overall higher interval mean value was noted in total session counts (13% > control) and a significant treatment group by time interaction occurred in ambulatory counts for males at top dose (15% > control). These slight changes were not considered to be biologically significant.
Acoustic startle response was performed on PND 20 and 60. Vmax was not altered but on PND 20, the overall Tmax was longer for females at 300 ppm (26.5±3.36 ms compared to control 24.9±3.24 and historical data of 22.3-27.3 mean of 24.2±1.44 ms). This isolated finding was not considered biologically meaningful.
Neuropathology: no gross findings were seen in brain or spinal cord on PND 21.
Brain weight/brain measurements: no compound related findings were seen.
Histopathology: a statistically significant increase in the mean height of the vertical thickness of the cortex (5.6%) in the 300 ppm females was not accompanied by any alteration in cortical height nor was there any changes in cortical thickness or height, or any other morphometric measurements for either male or females at PND 72.

C ANALYSIS OF ZETACYPERMETHRIN IN MILK

Range-finding study:

Zetacypermethrin was present in dam milk and plasma, increasing with increasing dose level. Litter plasma indicated similar dose proportionality on PND 5 and PND 21 and levels were similar to those observed in dams. Milk concentration of zetacypermethrin was proportional to administered dose. The presence of zetacypermethrin in maternal milk indicates that zetacypermethrin is transferred from maternal vasculature into milk, and thus, milk is a route of excretion. Milk concentrations increased from lactation day 4 to 11 and remained relatively constant from day 11 to day 17.

III. CONCLUSION

Range-finding study:

The analytical determinations of zetacypermethrin concentrations in milk samples of dams exposed to diets containing 50, 80, 300 and 350 ppm and in plasma samples from pups confirmed that pups were adequately exposed to the compound during lactation. Based on lower F0 body weights and/or food consumption during gestation and/or lactation in the 300 and 350 ppm groups, lower mean F1 male and female pup weights in the 300 and 350 ppm groups, and a decreasing trend in motor activity at all dose levels for males and at 300 and 350 ppm for female pups, dietary concentrations of 50, 125 and 300 ppm zetacypermethrin were selected for the main study.
Although occasional statistically significant differences were obtained in some offspring behavioral parameters and in one of 32 brain morphometric measurements, these apparent alterations did not occur to a degree or in a manner suggesting a compound-related pattern of neurotoxicity. According to the applicant, the results of the behavioral testing battery and the neuropathology assessments suggested no CNS domain-, age- or dietary-related adverse pattern of developmental neurotoxicity in the offspring.

The RMS agrees with the setting of NOAEL maternal and developmental toxicity at 125 ppm and consideres that the few measures affected at top dose in conjunction with other signs of toxicity including systemic toxicity, such as decreased body weight and body weight changes are not persuasive evidence of a direct neurotoxic effect.
NOAEL maternal and developmental toxicity = 125 ppm (9mg/kg bw/d) based on the decreased body weight, body weight changes and food consumption in dams and decreased body weight and body weight changes in litters.

Additional data taken from the open literature:

Report: -456003
A dose range-finding oral toxicity study of beta-cypermethrin in rat pups (listed in the DAR of beta-cypermethrin under Annex B.6.7 c

Report -456005
An oral (gavage) developmental neurotoxicity study of beta-cypermethrin in rats (listed in the DAR of beta-cypermethrin under Annex B.6.7 d)

Remark: In bilateral discussions with the Rapporteur Belgium it was agreed to perform a targeted study with alpha-cypermethrin to address the critical endpoints found for beta-cypermethrin and thereby address the concerns of the rapporteur. At this point it is referred to the range finder and the main DNT study in the DAR from Beta-cypermethrin, the executive summary as given in the DAR is presented, and the relevant endpoints found in the beta-cypermethrin study are summarized in table form to specify the critical endpoints to be addressed in the screening DNT study with alpha-cypermethrin. The study with alpha-cypermethrin is presented under CA 5.7.1/3.

Report -456003*: A dose range-finding oral toxicity study of beta-cypermethrin in rat pups (listed in the DAR of beta-cypermethrin under Annex B.6.7 c*

Executive summary

Beta-cypermethrin was administered by oral gavage to CRl:CD(SD)BR strain pre-weanling, rat pups from postnatal day (PND) 10-16. Initially (Phase I)doses of 0,3, 12, and 30 mg/kg bw/day were administered to 10 pups/sex/group, however following mortalities at the top two doses this phase of the experiment was terminated. In Phase II, new pups were assigned to treatment groups and dosed from PND 10 to 16.
Treatment related mortalities occurred between PND10-13 and were observed in pups at doses ≥4 mg/kg bw/day. Of the 4 males receiving 12 mg/kg bw/day, thee were found dead on PND11 and the remaining male was euthanized and discarded without examination on day 11.

Report -456005: ***An oral (gavage) developmental neurotoxicity study of beta-cypermethrin in rats (listed in the DAR of beta-cypermethrin under Annex B.6.7 d)***

Executive Summary

The developmental neurotoxicity of beta-cypermethrin in Crl: (SD)Br strain rats was investigated in two separate phases. In Phase I, 25 dams/dose were dosed by oral gavage from gestation day (GD) 6 through to PND 20 with 3, 12, 30 mg/kg bw beta-cypermethrin in aqueous CMC. Pups of this group were potentially exposed in utero and through nursing during lactation. In Phase II, 25 dams/dose were dosed by oral gavage from GD 6 through to PND 9 with 0.5 mg/kg bw. Pups in Phase II were potentially exposed in utero and through nursing until day 9 and were then administered 0.5 mg/kg bw/day by oral gavage from PND 10-16. No mortality and no abnormalities at necropsy were observed in the maternal rats. Dams of the 30 mg/kg bw dose group showed treatment related effects including clinical signs of toxicity and reduction in body weight gain during lacation at doses >= 12 mg/kg bw. Treatment related effects in pups of Phase I were limited to increased motor activity at 30 mg/kg bw/day on day 13 after lactational exposure. Pups of Phase II (direct gavage group) produced clinical signs of toxicity, decreases in body weight during direct treatment, clonic convulsions, altered grooming and deaths.

Determination of endpoints considered relevant to be addressed within a targeted screening DNT study with alpha-cypermethrin

The DNT study with beta-cypermethrin has induced a limited set of target parameters which are characteristic for acute neurotoxicity. A summary of effects is listed in the following table.

Table 5.7.1-3: Summary of effects found in the DNT study performed with beta-cypermethrin as taken from the respective DAR

Substance	Beta-cypermethrin (CA 5.7.1/2)	
Strain of rats	SD rats	
Exposure of dams administration route vehicle dose [mg/kg bw/day] Period of exposure	 gavaged aqueous CMC 0-3-12-30 GD6-PND20	 gavaged aqueous CMC 0-0.5 GD6-PND9
Exposure of pups administration route vehicle dose [mg/kg bw/day] Period of exposure	No direct exposure but via milk	 gavage aqueous CMC 0-0.5 PND10-16
Mortality	-	yes (see Range finder in not-pre-exposed pups at a dose ≥ 4mg/kg bw)
Detailed clinical observations n pups	No clinical signs	PND10-16: tremors, clonic convulsions, carangiform ataxia, straub tail
Litter weight	-	PND 10-17:↓ **BW 93%,** PND 10-17:↓ **BWG 91%**

Substance	Beta-cypermethrin (CA 5.7.1/2)	
FOB (PND 4, 11, 21, 35, 45, 60)	-	↑ grooming counts (PND11)
Total motor activity counts:	30 mg/kg bw: PND13: trend for ↑MA PND 21: - PND 61:-	PND13: trend for ↓MA ♂/ ↑MA ♀ PND 21: ↑ MA ♂
Sensory function - Acoustic startle response (PND 20 & 60)	-	↓ startle response (PND 20 & PND 60)
Biel maze test (PND 22 & 62)	-	↓ mean time and error ♀ (PND 62)*
Neuropathology (PND21 & 72)	-	-
Brain weight and dimension (PND21/72)	-	-
Histopathology CNS / Peripheral NS (PND 21/72)	-	-

-: parameter was not affected in the study;
*: a reduction of mean time and error in the biel maze test is not considered adverse but reflects normal variability of this parameter.

Beta-cypermethrin induced mainly acute neurotoxic effects in the direct dosing phase and on PND21 combined with some changes of body weight / body weight development. Effects seen at a later stage around PND60 were effects of questionable relevance as for example the effects seen in the Biel maze test which indicated reduced time and error in females (not considered adverse), or reduced startle response, which was also seen on PND20. Furthermore, no macroscopic or microscopic changes of the central or peripheral nervous system or changes of the brain weight and dimension were induced.

Based on the request of the rapporteur, BASF agreed to perform a targeted developmental neurotoxicity study copying the study design of beta-cypermethrin with the exception to go not over the period PND21 as the data suggest main . In the following the data on alpha-cypermethrin are presented.

Report:	CA 5.7.1/3 [redacted] ~~2014~~ 2015 a BAS 310 I (Alphacypermethrin) - Developmental neurotoxicity screening study in Wistar rats - Oral administration of the dams and pups (gavage) 2015/1001621
Guidelines:	~~OPPTS~~ EPA 870.6300, OECD 426
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Remark (Jan-2015): ~~The study is not finalized yet and data on stability, homogeneity and concentration control, pathological examinations of animals and neuro-histopathology are missing. The data were summarized by the author of the dossier to the best of knowledge from the raw data. Due to the change of dose regimen within the dose groups the values were manually split to present the data of Cohort 1 and Cohort 2-4 independently. Statistic was performed. The data are not QAU-checked and might change slightly in the QAU-checked final report.~~

Update (Nov- 2015): The update adds data on stability, homogeneity and concentration control, pathological examinations of dams and pups and examination of pups brain (weight, length and width). Furthermore, in a separate study (Doc ID 2015/1175543, included in the dossier in Chapter CA 4 /Analytical methods) data on the alphacypermethrin content in the pups, separated into brain and carcass, are presented. The update is highlighted in yellow.

Executive Summary

The aim of this study was to investigate the clinical effect of BAS 310 I (alpha-cypermethrin) on the embryonic, fetal and pre-weaning development of the nervous system. For this purpose, 25 pregnant female Wistar rats were treated with BAS 310 I by oral gavage in aqueous CMC from gestation day (GD) 6 through postnatal day (PND) 8 and their offspring from PND10 to PND 21. The study was splitted in two phases: Cohort 1 dams and pups were administered 0.5, 2, or 5 mg/kg bw/day. Because of excessive toxicity and lethality in the high-dose pups (test group 3: 5mg/kg bw/d) after direct dosing, the high dose test group was terminated. As the directly dosed mid- and low-dosed pups still exhibited adverse clinical symptoms in a dose-dependent fashion, the dose in cohort 2-4 pups was reduced to a constant dose of 0.25 mg/kg bw, irrespective of the pre-treatment of dams at 0.5 or 2 mg/kg bw/day. Furthermore, the body burden of PND4 and PND10 pups prior to direct treatment was determined.

Neurotoxicity was neither induced in dams nor in pups prior to the onset of direct pup dosing. This is in line with the analytical determination of alpha-cypermethrin in PND 4 and 10 pups, which revealed that alphacypermethrin is mainly deposed in the carcass of the pups, but does not reach the brain in relevant amounts.
Acute treatment-related mortality was induced by direct pup dosing at 2 and 5 mg/kg bw/day starting on PND10 while signs of neurotoxicity were observed down to 0.5 mg/kg bw/day. A 50% reduction of the pup dose to 0.25 mg/kg bw/day - while remaining the pre-treatment of dams until PND 8 at 0.5 and 2 mg/kg bw/day - resulted in similar signs of neurotoxicity, however reduced in incidence and severity in dependence of the maternal pretreatment.

Apart from the clinical symptoms, pup development was rather unaffected in the surviving animals in all test groups as shown by unchanged pup weights/weight gain and absence of necropsy findings. Motor activity measurements did not reveal any significant treatment-related changes. Regarding neuropathology, no treatment-related findings in brain weights, gross pathology and length and width measurements of the brain were found in any of the groups.

The analytical investigations of PND 10 pups revealed a body burden of 7 µg/kg bw in low dose pups. This internal body burden, corrected for bioavailability of 46%, together with the external dose of 250 µg/kg bw can be considered as **calculated LOAEL at 265 µg/kg bw/day**. Considering the internal dose of 101 µg/kg bw at PND4 as systemic NOAEL, and corrected for bioavailability of 46% ends up in a **calculated NOAEL of 220 µg/kg bw**.

Altogether, the data show that there occurs exposure via milk which still leads to measureable amounts of alphacypermethrin after a two-days treatment-free interval. However, direct pup dosing is an extreme method for pre-weanling pups, and of no direct relevance to the overall human or ecotoxicological risk assessment. Therefore, as discussed in the "Reasoning for the appropriateness of dietary DNT studies for alpha-cypermethrin" (see above) this study is not used for the human risk assessment but the dietary developmental neurotoxicity study with zeta-cypermethrin is considered adequate.

(DocID 2015/1001621)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	BAS 310 I (Alphacypermethrin)
Test substance:	01/0265-5
Description:	solid / white
Lot/Batch #:	PMAM000622
Purity:	99.2%
Stability of test compound:	The test substance was stable under storage conditions over the test period (expiry date 12 Dec 2015)
2. Vehicle:	CMC (1%)
3. Test animals:	
Species:	Rat (animals time-mated by the breeder)
Strain:	Crl:WI(Han)
Sex:	Female
Age:	About 10-12 weeks (at arrival)
Weight at dosing (range of means):	females: 200.3 – 204.9
Source:	Charles River Laboratories, Research Models and Services, Germany GmbH
Acclimation period:	6 days
Diet:	Ground Kliba maintenance diet mouse/rat "GLP", ad libitum

Water:	water, ad libitum
Housing:	single housing in polycarbonate cages type III (exception: during rearing up to weaning 1 dam with her litter)
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	15 per hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 08-Sep-2014 – 22 Sep 2015
(In life dates: 14-Sep-2014 (start of administration) to 02-Dec-2014 (necropsy)

Analytical report Doc ID 2015/1175543:
Dates of experimental work: 21-Jul-2015 - 11-Sep-2015

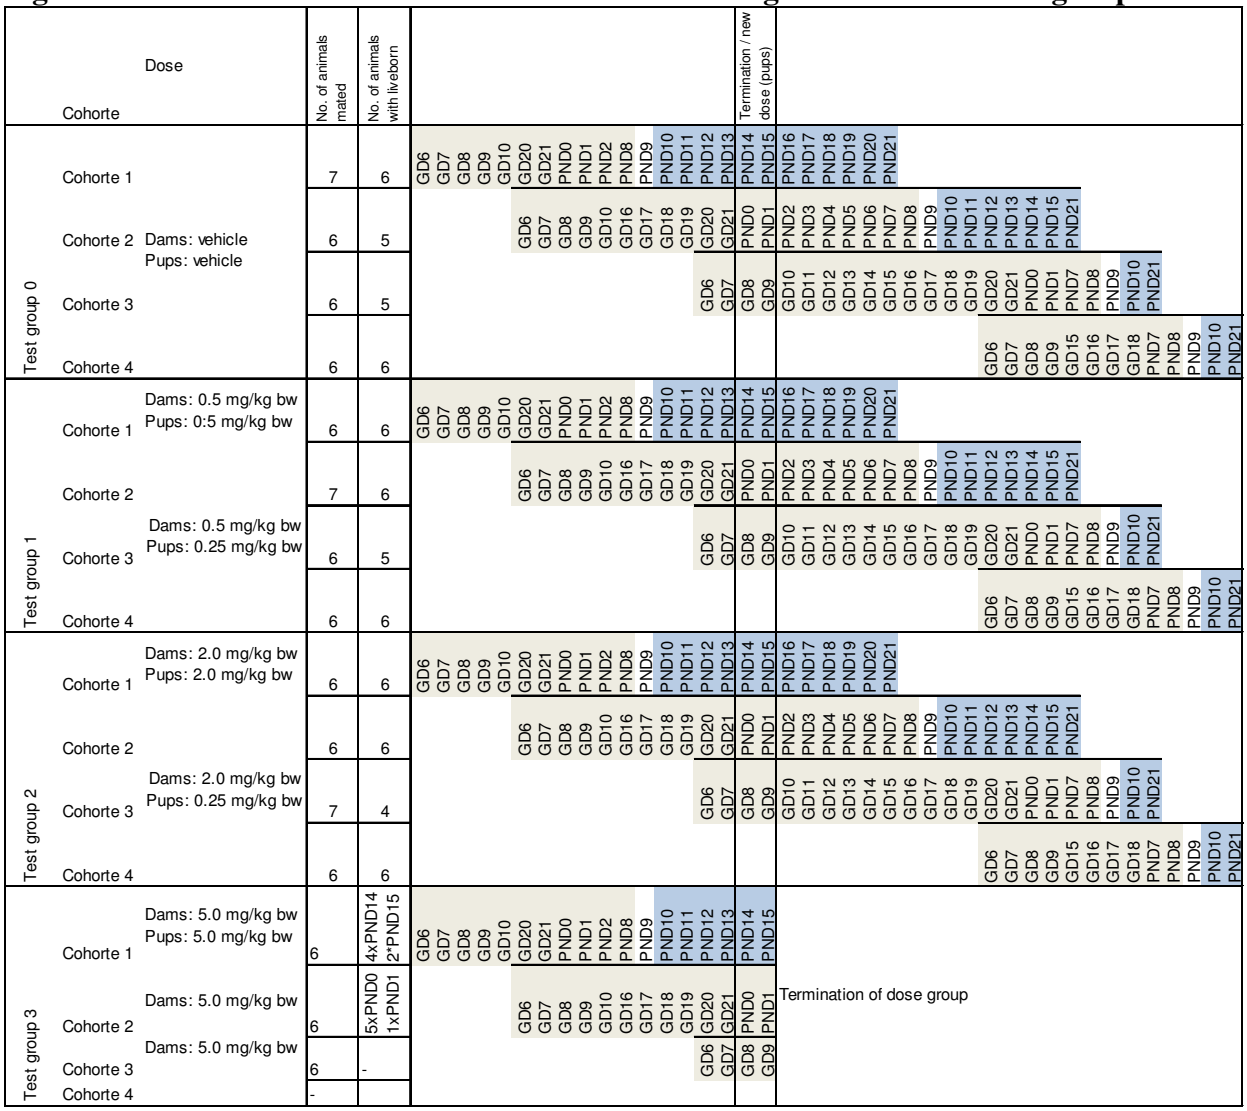
2. Animal assignment and treatment:
The animals paired by the breeder (time-mated animals) were supplied at noon on the day of evidence of mating; this day is referred to as GD 0 and the following day as GD 1. The dams were allowed to deliver and rear their pups until postnatal days (PND) 4 or 22. BAS 310 I was administered by oral gavage to groups of 25 dams at concentrations of 0.5, 2, and 5 mg/kg bw/day from GD 6 to PND 8. The administration volume was 2 mL/kg bw. Animals during parturition were not treated. Thereafter, pups of Cohort 1 were dosed by oral gavage with 0.5, 2, and 5 mg/kg bw from PND 10 onwards. Based on the severe clinical findings in the pups of dose group 3 (5 mg/kg bw/day) all group 3 animals were killed for humane reasons. Furthermore the dose in group 1 and 2 was reduced in a way, that the pups of cohorts 2, 3 and 4 were dosed equally with 0.25 mg/kg bw.

Table 5.7.1-4: Overview on dam assignment to cohorts and applied doses

Cohort 1					
	Group	**0**	**1**	**2**	**3**
	Dose dams	**0 mg/kg**	**0.5 mg/kg**	**2 mg/kg**	**5 mg/kg**
	Dose pups	**0 mg/kg**	**0.5 mg/kg**	**2 mg/kg**	**5 mg/kg**
	Cohort 1 dams	1-7	26-31	51-56	76-81
Cohort 2-4					
	Group	**0**	**1**	**2**	**-**
	Dose dams	**0 mg/kg**	**0.5 mg/kg**	**2 mg/kg**	**-**
	Dose pups	**0 mg/kg**	**0.25 mg/kg**	**0.25 mg/kg**	**-**
	Cohort 2 dams	8-13	32-38	57-62	82-87
	Cohort 3 dams	14-19	39-44	63-69	88-93
	Cohort 4 dams	20-25	45-50	70-75	-

Figure 5.7.1-1 shows the chronological order of the Cohort 1-4 treatment. The time point of termination of group 3 is marked and illustrates that PND14 and PND15 as well as PND0 and PND1 pups and dams of GD8 and 9 were affected by the test group 3 termination.

Figure 5.7.1-1: Schematic illustration of animal assignment to treatment groups



3. Test substance preparation and analysis:
For the test substance preparations in 1% Carboxymethylcellulose suspension in drinking water, the analytical results of the stability verification were taken into account. The specific amount of test substance was weighed, topped up with 1% Carboxymethylcellulose (CMC) suspension in drinking water in a calibrated beaker and intensely mixed with a homogenizer. During administration, the preparations were kept homogeneous with a magnetic stirrer.
The stability of the test substance in 1% CMC suspension in drinking water at room temperature over a period of 7 days had been verified prior to the start of the study (Project No.: 01Y0265/01Y014) for the concentration 0.025 g/100 mL and after study commencement for the reduced concentration of 0.0125 g/100 mL (Project No.: 01Y0265/01Y016). From the low- and high-dose formulations each, 3 samples were withdrawn from the top, middle and bottom of the preparation vessel for homogeneity and concentration control analyses. In addition, three samples each were withdrawn from the adapted dosing formulations for pups (test group 1 and 2).

4. Statistics:
Means and standard deviations (S.D.) of each test group were calculated for several parameters whenever possible. The following statistical analyses were carried out or will be carried out in the final:

Parameter	Statistical test
Food consumption (parental animals), body weight and body weight change (parental animals and pups; for the pup weights, the litter means were used), duration of gestation, number of pups delivered per litter,	DUNNETT test (two-sided)
Different indices (e.g. mating, fertility, gestation index), Females with liveborn, stillborn, all stillborn pups; Number of live, stillborn, dead pups, pups cannibalized, sacrificed moribund and different indices (e.g. viability index, lactation index) and number of litters with necropsy findings in pups	FISHER´s exact test
Proportion of pups with necropsy findings per litter	WILCOXON test (one-sided)
Motor activity, brain weights	KRUSKAL-WALLIS test (two-sided) and WILCOXON test (two-sided)
Brain measurements length, width, separately for cohort 1 and cohort 2-4	WILCOXON-test (one-sided-) with Bonferroni-Holm-Adjustment

C. METHODS

1. Observations:

Clinical examinations of dams

During the study, all animals were observed for any clinically abnormal signs. A check for moribund and dead animals was made twice daily from Mondays to Fridays and once daily on weekends and public holidays. A cage side examination was performed at least once daily for any signs of morbidity, pertinent behavioral changes and/or signs of overt toxicity.
The parturition and lactation behavior was generally evaluated in the morning in combination with the daily clinical inspection of the dams.

Clinical examinations of pups

Status (sex, liveborn or stillborn) and number of all pups delivered were determined as soon as possible after birth. At the same time, the pups were also examined for gross-morphological changes.
Regarding viability/mortality a check was made for any dead or moribund pups twice daily on workdays or once daily on weekends or public holidays.
All live pups were examined daily for clinical symptoms (including gross-morphological findings) during the clinical inspection of the dams.

Detailed clinical examinations of pups

A detailed clinical observation (DCO) was performed in all pups on PND 4 after standardization and thereafter on PND 10, 12, 14, 16, 18 and 20. For observation, the animals were removed from their cages and placed in a standard arena (50x37.5 cm with a lateral border of 25 cm) for at least 15 seconds per animal. The examination was carried out about 3-4 hours after test substance administration based on the time of appearance of clinical findings during the daily clinical observations. The scope of examinations and the scoring of the findings that were observed were based on the current index of findings in GROSSE-Reprotox software and includes but is not limited to the following parameters listed:
Abnormal behavior in handling, fur, skin, posture, salivation, respiration, activity/arousal level, tremors, convulsions, abnormal movements, gait abnormalities, lacrimation, palpebral closure, exophthalmos, assessment of the urine discharged during the examination, pupil size.

Motor activity measurement of pups

10 males and 10 females per group were selected. The motor activity (MA) was carried out on PND 17 and 21 (in a randomized sequence on each examination day). For this purpose, the animals were placed in polycarbonate cages type III for the time of measurement. The examinations were performed using the TSE Labmaster System supplied by TSE Systems GmbH, Bad Homburg, Germany. Eighteen beams are allocated per cage. The number of beam interrupts was counted over 12 intervals of 5 min each. The sequence at which the animals were placed in the cages was at random. The animals were given no food or water during the measurements.

2. Body weight:

Body weight of the parental females was determined on GD 0, 6, 8, 10, 13, 15, 17, 19, and 20. Females with litter were weighed on the day of parturition (PND 0) and on PND 4, 7, 9, 14, and 21.
The pups were weighed on the day after birth (PND 1) and on PND 4, 7, 10, 11, 13, 15, 17, 19, and 21.

3. Food consumption:

Food consumption of the dams was determined for GD 0-6, 6-13, and 13-20. Food consumption of the females, which gave birth to a litter, will be determined for PND 0-4, 4-7, 7-14 and 14-21.

4. Pathology and histopathology:

Necropsy

On PND 22, the dams were anesthetized with isoflurane and decapitated and assessed by gross pathology. Pups with scheduled sacrifice were anesthetized with isoflurane and sacrificed with CO_2, except for those 10 male and female pups necropsied with regard to the question of neuropathology, which were subjected to deep anesthesia with isoflurane and sacrified by perfusion fixation. SOERENSEN phosphate buffer was used as rinsing solution, and neutrally buffered 4% formaldehyde solution was used as a fixative.
Afterwards, the organs were assessed macroscopically, and in case of notable findings, were evaluated on a case-by-case basis, depending on the type of finding noted.

All stillborn pups and all pups that died before weaning were examined externally, eviscerated and their organs were assessed macroscopically.

The perfusion fixed pups were necropsied with regard to the question of neuropathology, and the visible organs were assessed by gross pathology as accurately as possible after a perfusion fixation. The cranial vault and the spinal cord were opened and the skin was removed from both hind extremities. In this state, the perfused animals were stored in neutrally buffered 4% formaldehyde solution for at least 48 h.

Pup brain weights, length and width

The terminal brain weight (including olfactory bulb) was determined after its removal but before further preparation. The terminal body weights were recorded to calculate the relative organ weights. The length and maximum width of the brain was measured in all animals (length: on a line extending from the rostral end of the frontal lobe to the caudal medulla oblongata of the cerebellum; width: pituitary region).

Pup organ/tissue fixation

The following organs/tissue specimens were carefully removed and processed histotechnically:

1. All gross lesions
2. Brain with olfactory bulb
3. Eyes with retina and optic nerve
4. Nose (nasal cavity)
5. Pituitary gland
6. Trigeminal ganglia (s. Gasserian)

The animals and the tissues or organ material remaining after trimming were stored in neutrally buffered 4% formaldehyde solution.

Neurohistopathology

The histotechnical processing of brain (olfactory bulb, prosencephalon with frontal lobe, diencephalon with parietal lobe, mesencephalon with occipital lobe and temporal lobe, pons, cerebellum and medulla oblongata) and brain-associated organs/tissues (eyes with retina and optic nerve), pituitary gland, trigeminus ganglia with part of nerve and nose were prepared in all animals per sex and group and gross lesions were prepared in all affected animals.

5. Blood/tissue sampling/

As many male and female surplus pups per group as available on PND4 and each 10 male and female pups on PND10 before treatment were sacrificed after isoflurane anesthesia with CO2, shock-frozen on dry-ice and stored at -80°C. From the thus collected frozen pups the brains were dissected in toto and brains as well as bodies were shipped frozen to PTRL Europe GmbH (Helmholtzstr. 22. Science Park I, 89081 Ulm, Germany) for the concentration investigation of the test substance.

These analyses were conducted as a separate GLP-study (PTRL Europe Study ID P3731G, BASF Doc ID 2015/1175543) but the results are reported here:

Analytical determination of alpha-cypermethrin in pup brain and body sample

The analytical determination of the concentrations of alpha-cypermethrin (Cis II) and possibly its isomers Cis I, Trans III and Trans IV in the pups brain and body samples was performed at PTRL Europe. The procedure was developed and validated at PTRL Europe based on QuEChERS extraction with subsequent clean-up and LC/MS/MS. All body samples were homogenized frozen using a knife mill. Brain samples from PND10 were homogenized frozen by hammering the respective samples in a plastic bag. Brain samples from PND 4 were homogenized frozen by pestling the tissue samples with a spatula.
The method used for analyzing the test material in the samples involved extraction and fortification with a solvent followed by LC/MS/MS analysis with an external standard.

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSES

Based on analytical results the stability of BAS 310 I in 1% CMC in drinking water over a period of 7 days at room temperature is given at a concentration of 0.2 mg/ml and for the reduced concentration of 0.125 g/L. All determined concentrations were in the range of 90 % - 110 % of the nominal concentration.

Concentration control analysis of all dose levels were determined at the beginning of the dam administration period and at the beginning of the F1 pup dosing.
The homogeneity of the low and high dose as well as of the dose used for F1 pup dosing (Cohorte 2-4) was determined with the samples used for concentration control analysis. Three samples (one from the top, middle and bottom in each case) were taken from the beaker with a magnetic stirrer running. Additional reserve samples were retained.

Table 5.7.1-5: Analysis of test-item concentration and homogeneity

BAS 310 I nominal conc. [g/100 mL]	Date of sampling	Date of analysis	Sample [#]	Analytical concentration [g/100mL]	% of nominal concentration	Mean ± RSD
0	14-Sep-2014	21-Oct-2014	2	0		
0,025	14-Sep-2014	21-Oct-2014	3	0,022	88,3	85,9 ± 3,4
			4	0,021	82,6	
			5	0,022	86,8	
0,10	14-Sep-2014	21-Oct-2014	6	0,092	92,5	
0,25	14-Sep-2014	21-Oct-2014	7	0,226	90,3	89,4 ± 0,9
			8	0,223	89,1	
			9	0,222	88,9	
0	23-Oct-2014	10-Dec-2014	11	0		
0,0125	23-Oct-2014	10-Dec-2014	12	0,012	95,2	87,2 ± 13,9
			13	0,01	73,2	
			14	0,012	93,1	
0,025	17-Nov-2014	10-Dec-2014	17R	0,021	83,8	
0,10	17-Nov-2014	10-Dec-2014	18R	0,075	74,7	
0,0125	02-Dec-2014	10-Dec-2014	19	0,012	93,5	

No test substance was detected in the vehicle control samples (samples 2 and 11).
The mean values of the test-item concentrations in the homogeneity samples were in the range of 85.9 – 89.4% of the target nominal concentrations and thus within the acceptable range of ± 15% of the target concentration for liquid suspensions.
The concentration in the single samples (6,17R, 18R and 19) was in the range of 74,7- 93,5% of the nominal concentration and two (17R, 18R) were below the 15% trigger of acceptable range for liquid suspensions. However, they still can be considered acceptable when all results are taken into account during the course of the study.

The relative standard deviations (RSD) of the samples 3-5 and samples 7-9 of 3.4% and 0.9% indicated the homogenous distribution of BAS 310 I in 1% CMC in drinking water. The RSD of the pup dosing samples for Cohorte 2-4 (sample 12-14) with a nominal concentration of 0.125 mg/ml was slightly higher with 13,9%. However, this slight deviation from the acceptance criterion (RSD up to 10%) is considered acceptable given the very low test substance concentration.

It is concluded that the results demonstrate the correctness of the concentrations of BAS 310 I in 1% CMC in drinking water.

B. OBSERVATIONS OF DAMS

1. Mortality

No dam died treatment-related during gestation or lactation. Due to premature termination of Group 3 based on severe pup toxicity 18 dams were premature sacrificed (Cohort 3 dams on GD 8 (6 dams); Cohort 2 dams on LD 1 (5 dams) and 2 (1 dam) and Cohort 1 dams on LD 14 (4 dams) and 15 (2 dams)). Cohort 4 animals of Group 3 were not started. All other dams survived until scheduled necropsy.

2. Clinical signs of toxicity

No treatment related clinical signs of toxicity were reported in dams during the entire study period up to the highest dose of 5 mg/kg bw.
Two high-dose dams (Nos.: 78 and 79) had no more pups alive on PND 11.

Comparison with beta-cypermethrin data as presented in the DAR 2013: Treatment related clinical signs of toxicity were observed in dams at doses ≥ 12 mg/kg bw. Therefore the data of alpha-cypermethrin are comparable at 5 mg/kg bw.

C. BODY WEIGHT AND BODY WEIGHT GAIN OF DAMS

Bodyweight was not affected in any treatment group compared to control neither during gestation nor during lactation phase (see Table 5.7.1-6).

The body weight change of the high-dose parental females was statistically significantly below the concurrent control values during GD 19 - 20 (about 25%, 9.4 g compared to 12.5 g in control (3.1 g less)) and during PND 8 - 14 (-11.4 g [vs.] 9.5 g in control).
The significantly reduced BWG from GD 19-20 is not considered treatment related but incidental because the BWG in the complete treatment phase GD6-20 was unaffected and the lower BWG of group 3 in the period GD 19-20 is a compensation of the higher body weight increase in the phase GD 6-19, which is 3g higher than the respective control. So the difference of 3 g is exactly that what group 3 dams have not gained in the period GD19-20.

Body weight gain during the lactation phase showed no significant change in the treatment phase between LD 0-8. There was no dose-related consistent trend observable between the treatment groups.

The significantly reduced body weight gain during PND 8 - 14 reflects the reduced food intake during this time period which is considered to be subsequent to reduced caloric needs (due to the low number of breast-fed pups), rather than an adverse effect of its own. In addition, this episode of reduced body weight gain fell into the treatment–free period of the dams from PND 8 onwards, which also indicates that this apparent effect is not treatment-related or adverse.
The body weight change of the mid- and low dose parental females was comparable to the concurrent control values throughout the entire study period.

#The number of animals which were pregnant and used for value derivation is given for the different groups. Based on the subdivision into 4 cohorts and the premature termination of group 4 only a variable number of animals were available for group 3 value determination. Any change in number of animals used for value derivation is given in square brackets.

Figure 5.7.1-2: Mean body weight of F0 parental females during gestation of F1 litters

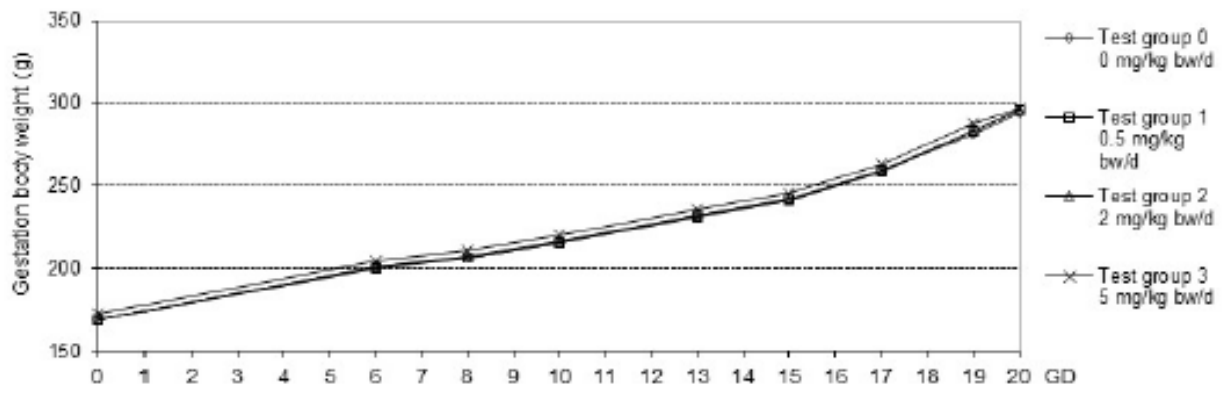

Figure 5.7.1-3: Mean body weight of F0 parental feamles during lactation of F1 litters

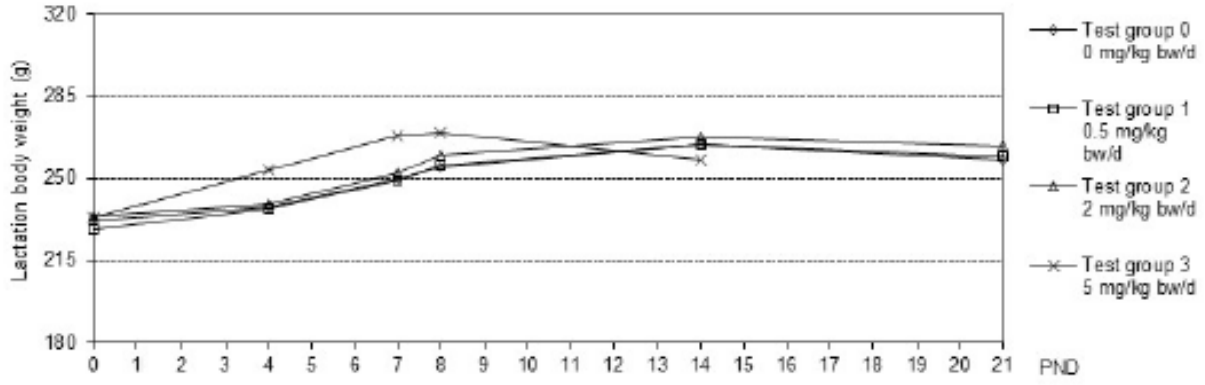

Comparison with beta-cypermethrin data as presented in the DAR 2013: Beta-cypermethrin showed as well no treatment related changes of body weight or body weight gain.

D. FOOD CONSUMPTION OF DAMS

No treatment-related or adverse differences of food intake were observed in any group during gestation and lactation .

The statistically significantly reduced food consumption in the high-dose parental females during LD 7-14 (-27%) clearly correlates with the corresponding number of breast-fed pups, keeping in mind that 2 out of 6 dams did not have any pups from PND11 onwards. Therefore this reduced food consumption is considered to reflect an adaption of food intake subsequent to reduced caloric needs rather than an adverse effect on its own. In addition this episode of reduced food consumption fell into the treatment–free period of the dams from PND 8 onwards, which also indicates that this apparent effect is not treatment-related or adverse.

day 14-21	60.8	63.5 / 104	63.1 / 104	- / -
day 0-21	44.3	46.5 / 105	46.1 / 104	- / -

*: $p \leq 0.05$; **: $p \leq 0.01$ (Dunnetts´ test; two-sided)

#The number of animals which were pregnant and used for value derivation is given for the different groups. Based on the subdivision into 4 cohorts and the premature termination of group 4 only a variable number of animals were available for group 3 value determination. Any change in number of animals used for value derivation is given in square brackets.

Comparison with beta-cypermethrin data as presented in the DAR 2013: Beta-cypermethrin showed as well no treatment related changes of food consumption.

E. FEMALE REPRODUCTION AND DELIVERY DATA

Female reproduction and delivery was unaffected up to the highest dose. As all females delivered by the breeder had successfully paired (plugs detected) the mating index was assumed to be 100% in all test groups. No effect on fertility index, or gestation index or duration of gestation was seen, number of live born or stillborn pups was comparable as well as the pup sex ratio.

Table 5.7.1-8: Summary of female reproduction and delivery data after administration of alpha-cypermethrin in the screening DNT study[#]

*: $p \leq 0.05$ ** : $p <= 0.01$ (Fisher´s exact test; one-sided)

[#]The lower number in Test group 3 is based on the premature termination of this group. The 7 animals of the 4th (last) cohort were not placed into the study and the 6 animals of the 3rd cohort were terminated in early pregnancy. Thus only 12 gestating females were available for the delivery of pups. The raw data indicated that the parameter "females with liveborn pups" is significantly reduced resulting in an gestation index of 71%, but this is based on study termination and no substance related effect, therefore the data were adapted to the number of females allowed to deliver. Due to termination of the study all parameters addressing a PND observation were not available.

n.a.: not applicable due to termination of the group 3

Comparison with beta-cypermethrin data as presented in the DAR 2013: The data are comparable showing in both cases no effect on reproduction and delivery data.

F. OBSERVATIONS OF PUPS

1. Mortality

In test group 3 (5 mg/kg bw/d) 42 pups died or were cannibalized, 41 of the decedents died after pup dosing commencing on PND 10. This high mortality rate and the severe clinical observations after direct dosing of the pups led to the termination of the high-dose group. Therefore, no viability or lactation indices were calculated for test group 3.
For test group 1 and 2 the viability index and the lactation index were comparable with the concurrent control (see litter data in Table 5.7.1-9 and Figure 5.7.1-4).

Table 5.7.1-9: Summary of mortality in pups

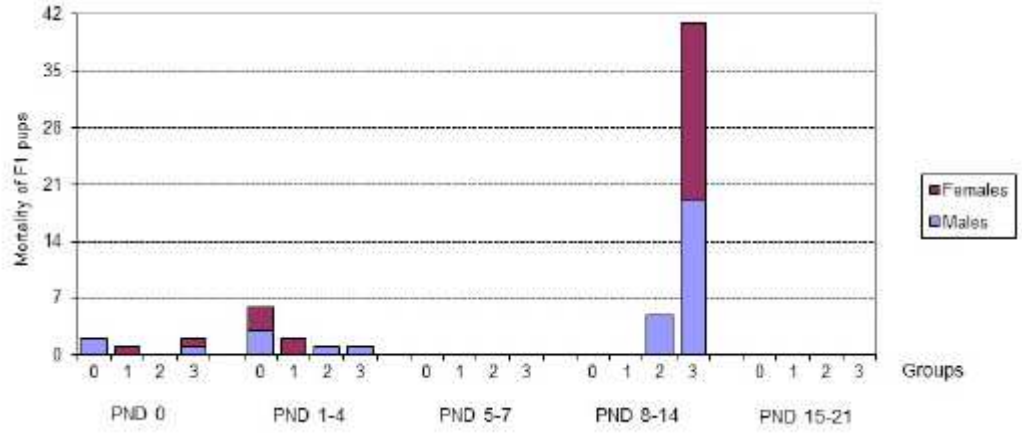
Figure 5.7.1-4: Mortality of F1 pups



The increased mortality was restricted to Cohort 1, where dams (dosed from GD6-PND8) and pups (from PND10 onwards) were gavaged with the same dose. The treatment-related mortalities in pups occurred between PND10 and PND14 and were observed in male pups at doses ≥ 2 mg/kg bw/day and in female pups at doses ≥ 5 mg/kg bw/day. Around 40% of the high dose pups died on PND 10 in both sexes. On PND11 additionally 7-8 % died and around 20 % were found cannibalized, followed by some further cannibalized pups on PND12 and 14. Based on the equal distribution of dead pups between high dose males (73%) and females (82%) a definite sex dependent susceptibility is not anticipated although already some mortality was seen in the mid dose males. However, on PND10 and 11 each 1 male pup died whereas 3 male pups suffered cannibalism on PND11. No mortality was seen in the group receiving 0.5 mg/kg bw/day.

[#] The cohort 1 contained each 6 pregnant animals of each dose group. Based on the mortality seen the treatment was changed for cohort 2-4; no statistical evaluation was performed on these data.

d- died; z-cannibalized

Based on the high mortality in cohort 1 the study design was changed: The high dose group was terminated while the dams dosed with 0, 0.5, and 2 mg/kg bw were continued. Though the pup doses were reduced to a constant dose of 0.25 mg/kg bw.

With this study design cohort 2-4 pups, treated with 0.25 mg/kg bw/day, showed no more treatment-related mortality either with dams pre-exposure to 0.5 or 2 mg/kg bw.

Pups died	0	0	1	1	1	0

* no. of pups not considering pups culled on PND4 or with scheduled sacrifice on PND10;

#Cohort 2-4 were those pups from litters #8-25, 32-50, and 57-75.

In conclusion, taking all the data of Cohort 1-4 together, it can be stated that no mortality occurred in pups after bolus administration of 0.25 or 0.5 mg/kg bw/day subsequent to a pre-exposure of dams to a dose of 0.5 mg/kg bw. In addition no mortality occurred when pups were administered 0.25 mg/kg bw and pre-exposure in dams was increased to 2 mg/kg bw.

Comparison with beta-cypermethrin data as presented in the DAR 2013: Mortality in pups with beta-cypermethrin was investigated at 1, 4 and 12/8 mg/kg bw/day in a range finder study. Mortality occurred in this test at a dose of 4 mg/kg bw/day (10% of animals died) and at 8 mg/kg bw/day (5/6 died) and at 12 mg/kg bw/day on (3/4 animals died). The main study with pre-exposed pups was performed at 0.5 mg/kg bw/day and induced no mortality. This is comparable to alpha-cypermethrin.

2. Clinical signs of toxicity

Cohort 1 as well as Cohort 2-4 pups showed no clinical signs during the lactation period until direct treatment started. Therefore the lactation exposure up to PND 9 did not induce adverse effects in pups up to a maternal dose of 5 mg/kg bw/day.

In Cohort 1 all litters treated with 0.5, 2 and 5 mg/kg bw were affected after commencement of pup dosing (see Table 5.7.1-12). The number of affected pups and the severity of findings increased dose-dependently. The number of affected pups was 23/51 (45%) at 0.5 mg/kg bw and 100% at 2 and 5 mg/kg bw. Treatment-related signs were restricted to tremors, twitching, convulsions and excessive grooming in group 1 (0.5 mg/kg bw), while group 2 pups (2 mg/kg bw) showed in addition hypothermia, vocalization and lateral position. Dose groups 3 (5 mg/kg bw/day) was terminated based on severity of effects and is not further considered for clinical observation.

Interestingly, in group 1 (0.5 mg/kg bw) the highest incidence of clinical signs was not observed directly after first treatment but in the phase PND14-17. Half of the litters (3/6) were unaffected during the first 4 days of treatment and one third (2/6) were unaffected in the last third of treatment (PND17-21). Excessive grooming was more pronounced in the first third of treatment, while twitching was rather seen at the end of the treatment.

*Based on premature killing of Group 3 dams/pups on PND 14 and 15 the data were restricted on PND10-13; single data when available were disregarded
n.a. not applicable based on termination of dose group

In Cohort 2-4 only marginal differences were seen on litter base; with 3 litters were free of symptoms in group 1 and 2 litters were free of symptoms in group 2 (see Table 5.7.1-13). A clear dose dependency was seen on pup level, where 21.2 % of the pups were affected when dams were treated with 0.5 mg/kg bw and 44% of pups were affected when dams were pre-treated with 2 mg/kg bw alpha-cypermethrin. An early effect in the low dose group on litter base was twitching, while tremors increased in the mid third of treatment. 14 of the 17 litters (82%) were free of symptoms in the last third of treatment. Pups reared by 2 mg/kg bw-treated dams showed in addition convulsion and a much higher incidence of tremors and twitching directly in the first treatment interval (PND10-13), whereas in the last third of treatment the effects were comparable with the mid dose group (13/17 litters were unaffected).

The effects seen in the different treatment groups indicate that lactational exposure plays a major role in development of different characteristics at least up to PND17. In the later period of treatment the effects seen are comparable and might represent rather the direct exposure to the bolus administered dose of pups. Whether this later phase represents the real symptomatic induced by the bolus administration alone or is still interfered with lactation exposure, or whether metabolic capacity or adipose tissue ratio is increased, remains open.

3. Clinical signs in pups in chronological order

A more detailed look into the characteristics of the effects induced by bolus administration of pups to 0.5 mg/kg bw/day and 0.25 mg/kg bw/day is performed in the following.

Bolus administration of 0.5 mg/kg bw/day to pups pre-treated by dams treated with 0.5 mg/kg bw induced effects in 45% of cohort 1 pups (see Table 5.7.1-12). Effects were first observed on PND11 in one pup showing severe tremors, followed by 19 pups showing slight tremors between PND12 and 20 (37.3%). Tremors were the predominant symptom and were observable over the complete interval of treatment with a slightly higher occurrence from PND15-20. Under this dose regimen pups showed excessive grooming (11.8%) in the early phase of direct dosing, while twitching was seen rather at the end (seen in 9.8% of pups). The data indicate that symptoms were distributed over the whole treatment group and only a small number of animals was repeatedly seen affected during the observation period, often with varying symptom. The percentage of affected pups per observation day stayed below 14%.

Table 5.7.1-14: Overview clinical signs in F1-Cohort 1/ group 1 pups dosed with 0.5 mg/kg bw (dam dosed with 0.5 mg/kg bw): individual clinical observations in chronological order

	Affected pup in a litter at day of observation [# litter-pup]

Clinical observations after reduction of the pup dose to 0.25 mg/kg bw/day while keeping pre-treatment of dams at 0.5 mg/kg bw induced effects in 32 of 151 pups (21.2%) (see Table 5.7.1-11). Symptoms were clearly reduced and less severe than in Group 1 pups of Cohort1, as they were restricted to slight tremors and twitching, which is a less severe form of tremors (see Table 5.7.1-13). Both symptoms were directly observed on PND10 and remained mainly until PND16 which showed the highest incidence with 6.6% of pups showing clinical signs. The average percentage of affected pups was around 3% allocated to 2-6 litters each day. From PND17 onwards tremors disappeared and twitching was the only reported clinical sign with no more than 2% of the pups being affected.
Compared to the pups of Cohort 1 which got the double dose by bolus application the spectrum of clinical signs here and the severity was clearly reduced under this dose regime and pup incidence was reduced from 45% to 21.2%. The dominant phase of clinical sign was PND 10 – 16.

Table 5.7.1-15: Overview clinical signs in F1-Cohort 2-4/ group 1 pups dosed with 0.25 mg/kg bw (dam dosed with 0.5 mg/kg bw): individual clinical observations in chronological order

Affected pups in total (%) **Affected litters in total (%)**	**32/151 = 21.2% (12 females, 20 males)** **14/17 = 82.4%**											

The clinical sings in pups from dams pre-treated with 2 mg/kg bw were more frequent and more severe (see Cohort 2-4, group 2, Table 5.7.1-14) compared to those seen in pups from mothers predosed with 0.5 mg/kg bw/day. This increased incidence was mainly seen in the first part of direct pup dosing (PND10-17) and is most probably due to the higher amount transferred with the milk. The percentage of pups showing tremors increased from 10.6 % to 27.9% (slight and moderate tremor incidence added). The percentage of pups showing twitching increased from 13.9% to 24.7% (see Table 5.7.1-14). Additionally clonic tonic convulsions were reported in one animal. Symptoms were directly observed on PND10 and were predominant in the first interval until PND17 with around 4 to 10% of pups affected in slightly less than half of the litters. After PND17 tremors ceased completely and only single pups showed twitching. The percentage of affected pups after PND17 stayed below 1.3% and was thereby comparable with the pups of the same Cohort but with the lower pretreatment of dams (0.5 mg/kg bw, see Table 5.7.1-15). This indicates that rather the later part reflects the direct dosing of pups.

Table 5.7.1-16: Overview clinical signs in F1-Cohort 2-4/ group 2 pups dosed with 0.25 mg/kg bw (dam dosed with 2 mg/kg bw): individual clinical observations in chronological order

The different characteristics within the first interval (PND10-17) of Cohort 2-4 group 1 and 2 pups (both dosed at 0.25 mg/kg bw/day) are clearly attributed to double exposure via lactation exposure. The abrupt reduction of symptoms around PND 17 in pups dosed at 0.25 mg/kg bw/day in both, the 0.5 mg/kg bw/day pre-treated and the 2 mg/kg bw/day pre-treated dams to less than 2% affected foetuses might indicate the end or a lower level of lactation exposure to alpha-cypermethrin. It remains to be determined if not pre-treated pups or pups reared from 0.25 mg/kg bw/day pre-treated dams would show symptoms.

4. Detailed clinical observation (DCO) of pups

A detailed clinical observation of pups was performed on PND 4, 10, 12, 14, 16, 18, and 20 in a standard arena.
Cohort 1 mid and high dose pups showed toxicity resulting in mortality, so that these groups were only summarized in the following table but were not further discussed.
Low dose bolus administration of 0.5 mg/kg bw/day to pups delivered from dams pre-treated with 0.5 mg/kg bw (Cohort 1, Group 1) induced slight tremors in 8 male and 8 female pups (see

Table 5.7.1-18) from all litters. Tremors were seen from PND12 onwards in males, and from PND 14 onwards in females. No effect was seen in both sexes at PND20. No significant sex difference was obvious. The percentage of affected pups was slightly lower (31.4%) than that in the general clinical observations (45.1%). Control animals did not show any abnormal findings besides one animal that died before DCO on PND 4.

Cohorte 1 Group data:

Cohorte 2-4 Group data:

Bolus administration of 0.25 mg/kg bw/day to pups delivered from dams pre-treated with 0.5 mg/kg bw (Cohort 2-4, Group 1; see Table 5.7.1-19) revealed in 1 male pup twitching of both hindlimbs. No other effect was seen. Females did not show any signs of neurotoxicity. As both sexes showed no significant differences no sex difference was obvious and this dose is considered near to the no observed effect level with a percentage of affected pups in DCO of 0.6%. Whether this dose would be a NOAEL in case of dams would be pre-treated with 0.25 mg/kg bw/day remains open.

Bolus administration of 0.25 mg/kg bw/day to pups delivered from dams pre-treated with 2 mg/kg bw (Cohort 2-4, group 2; see Table 5.7.1-20) revealed slight tremors in 4 male pups between PND 10 and PND14. No effect was seen from PND 16 onward. The percentage of affected pups in the DCO was considerably lower (2.7%) than the percentage of affected pups in the general clinical observations (21.2%).

Comparison with beta-cypermethrin data as presented in the DAR 2013: The clinical signs in pups treated with beta-cypermethrin as described in the DAR 2013 were clonic convulsions, carangiform ataxia and straub tail at 0.5 mg/kg bw. With alpha-cypermethrin dosed to dams and pups equally at 0.5 mg/kg bw slight and moderate tremors, twitching, clonic convulsions, and excessive grooming were reported. However, no permanent seizures like straub tail were seen with alpha-cypermethrin.
Both alpha- and beta-cypermethrin are considered comparable in the development of neurotoxic symptoms.

G. BODY WEIGHT AND BODY WEIGHT GAIN OF PUPS

Body weights of male or female pups were not significantly affected in any treatment group of cohort 1 when compared to control (see Table 5.7.1-21 and Figure 5.7.1-5). The relative body weights of the treated pups were within 95% – 103 % at PNDs 1, 4, 7, 10, 11, 13, 15, 17, and 21, with the exception of the high dose male and female pups, which changed to 88% compared to control animals in males and 108% in females after the commencement of treatment.
Body weight gains of these high dose pups showed statistically significant reductions of mean body weight gains during PND 11-13 and corresponding increases during PND 11-15 which are related to the intoxication and death of a big proportion of high-dose pups after commencement of direct pup dosing.

The increased body weight gain in the mid-dose group during PND 15-17 is considered as incidental findings, as the respective body weight and the weight gain over the complete weaning period was unaffected. Further evidence is based on the litter weight, which was in addition unaffected at PND15 and 17 with 100 % and 102% of control (see Table 5.7.1-22).

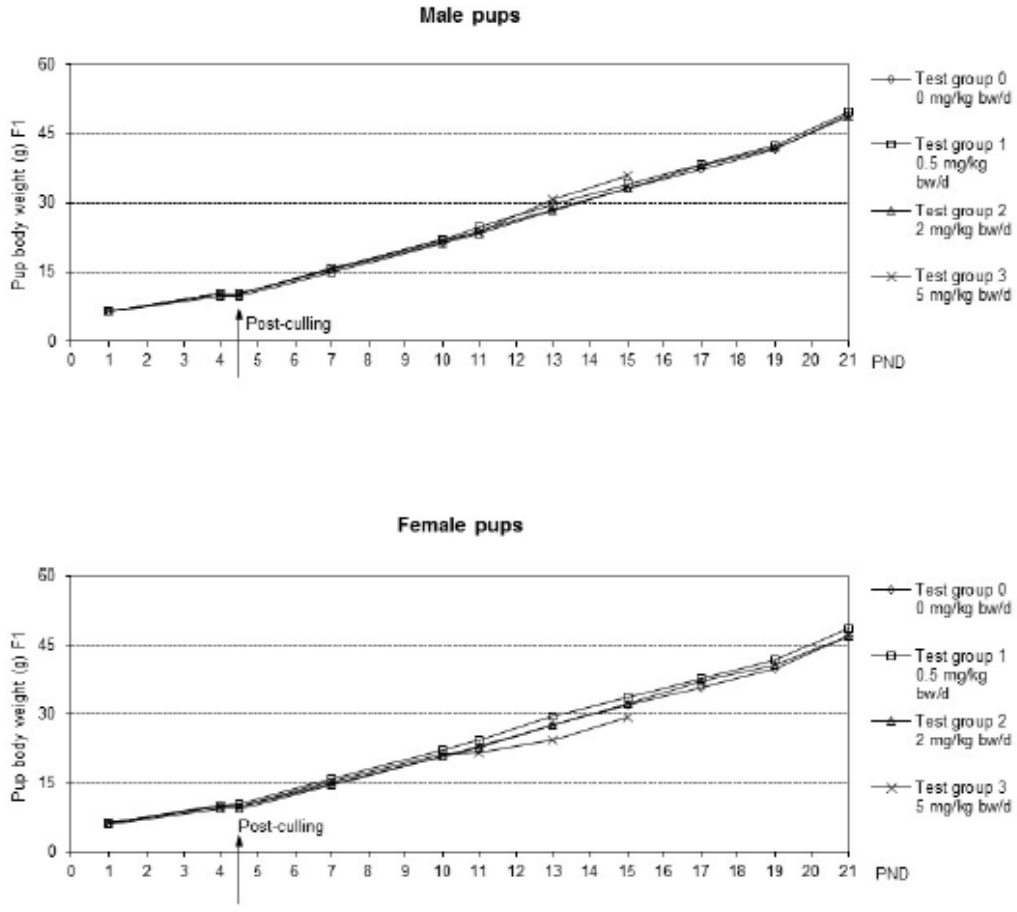
n.a.: not applicable due to termination of the group 3

Figure 5.7.1-5: Mean body weight of F1 pups (Cohort 1)



Bodyweights of male or female pups as well as litter weights were not affected in any treatment group of cohort 2-4 when compared to control (see Table 5.7.1-23, Table 5.7.1-27 and Figure 5.7.1-6). The relative body-/litter weights of the treated pups of groups 1 and 2 were within 99% - 105% and 99% - 103% of the body-/litter weights of the control animals at PNDs 1, 4, 7, 10, 11, 13, 15, 17, and 21.

Furthermore, body weight gains as well as litter weight gain were also not affected by treatment. Body weight- and Litter weight gains ranged between 98% - 100% compared to control animals. There was no dose-related consistent trend observable between the treatment groups regarding body weight or body weight gain.

Data from treatment group 3 were not available for cohort 2-4 as the dose group was terminated at PND 1.

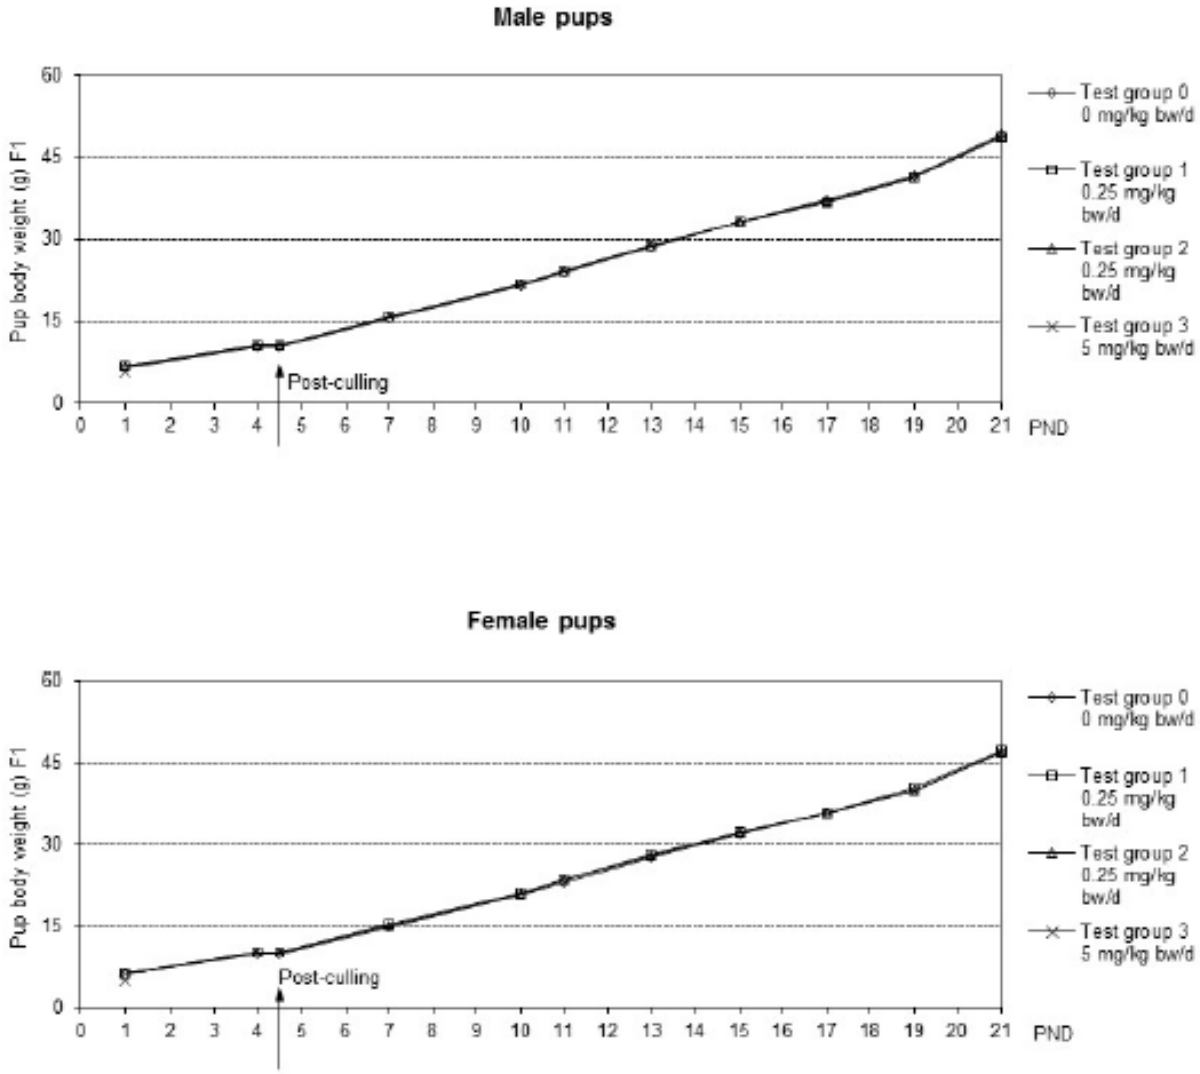
Figure 5.7.1-6: Mean body weight of F1 pups (Cohort 2-4)



Comparison with beta-cypermethrin data presented in the DAR 2013: Body weight reduction was seen in pups treated with 0.5 mg/kg bw/day beta-cypermethrin during direct administration of the test substance (PND10-16) but restored after cessation of dosing to values within historical control. With alpha-cypermethrin at 0.5 mg/kg bw no effect on body weight or bodyweight gain was seen during the treatment period (PND 10-21).

H. Clinical assessment of neurotoxicity

MOTOR ACTIVITY (MA)

Motor activity measurements of Cohort 1 (low and mid dose) and Cohort 2-4 pups on PND17 and PND 21 revealed two significantly reduced individual values (see Table 5.7.1-25). One significant lower MA was seen reduced at the onset of measurement on PND21 in Cohort 2-4 female pups from group 1 (dosed with 0.25 mg/kg bw/day; dams pre-dosed with 0.5 mg/kg bw). The other lower MA was seen at interval 7 on PND21 in Cohort 2-4 female pups from group 2 (dosed with 0.25 mg/kg bw/day; dams pre-dosed with 2 mg/kg bw). Both changes are isolated findings. These two alterations did not occur to a degree or in a manner suggesting a compound-related pattern of neurotoxicity.
No significant change as indication of treatment-related effect was seen in the mean total motor activity counts (see Table 5.7.1-26). The respective graphs are listed below.

Table 5.7.1-25: Mean motor activity on PND 21 in female pups of Cohort 2-4 (N = 7 pups)

I. NECROPSY

1. Necropsy

Necropsy of dams on lactation day 21

No treatment related findings were observed.

Necropsy of Cohort 1 Pups on PND 21

In the high-dose F1 pups increased affected pups per litter rates were observed for gas bubble (31.2% vs. 0% in control), blood coagulum in renal pelvis (15.2% vs. 0% in control) and hemorrhagic testis (1.9% vs. 0% in control). This resulted in a higher rate of total pup necropsy observations (39.7% vs. 7.3% in control).

A few F1 control pups showed spontaneous findings at gross necropsy, such as incisors sloped, hemorrhagic thymus, empty stomach, dilated renal pelvis and fluid-filled thoracic cavity.

Table 5.7.1-31: Summary of Pup Necropsy Observations in cohort 1 pups

Statistics: F= fisher's exact test; W= Wilcoxon-test, *: p<=0.05; ** = p<=0.01;

Necropsy of Cohort 2-4 Pups on PND 21
No treatment related findings were observed.

A few F1 pups showed spontaneous findings at gross necropsy. Incisors sloped, hemorrhagic thymus, empty stomach and fluidfilled thoracic cavity were seen in control animals only while dilated renal pelvis showed no relation to dosing. Diaphragmatic hernia was an isolated finding in one group 2 pub. Although the incidence is slightly above the historic control (pup incidence 0.7% vs. 0.5% HCD, Litter incidence 5.9% vs 4.2% HCD) the affected Pups/litter incidence is within the Historic control data (0.7% vs. 2.1% HCD). Furthermore this finding was not seen in Cohort 1 animals despite higher dose levels. Therefore all these findings were not considered to be associated with the test substance.

2. Gross lesions

No gross lesions were observed in Cohort 1 and Cohort 2-4 pups.

3. Organ weight

Neither cohort 1 nor cohort 2-4 pups showed significant differences of brain weight or brain to body weight when compared to the control group (see Table 5.7.1-38).

Table 5.7.1-32: Absolut and relative Brain Weights of Cohort 1 and Cohort 2-4 pups

Sex		Males					Females				
Organ weight	Dose Dam/Pup [mg/kg bw]	Absolute weight	Δ%	Relative weight [% of bw]	Δ% #	Note	Absolute weight	Δ%	Relative weight [% of bw]	Δ% #	Note
Cohort 1; 3 pups

Statistics: Kruskal-Wallis and Wilcoxon test (two-sided): *: p<=0.05; ** = p<=0.01;

4. Length and width of brain

No statistical differences were found between control and treated pups regarding brain measurements of width and length, neither for Cohort 1 nor Cohort 2-4 pups (see Table 5.7.1-33).

Table 5.7.1-33: Brain width and length of Cohort 1 and Cohort 2-4 pups

Brain measurement		Males				Females			
	Dose Dam/Pup [mg/kg bw]	Length	Δ%	Width	Δ%	Length	Δ%	Width	Δ%

Statistics: Wilcoxon test with Bonferoni-Holm-Adjustment (one-sided): *: p<=0.025; ** = p<=0.005;

5. Histopathology / Neurohistopathology

Neurohistopathology was not investigated as this was not affected in the DNT studies with Beta- and Zeta-cypermethrin.

J. Analytical determination of BAS 310 I in PND 4 and PND 10 pups before treatment

The residues of alpha-cypermethrin in the pups brain and residual body at PND 4 and PND10 are summarized in Table 5.7.1-39 given as mg alphacypermethrin per kg tissue. The measurement was done before the direct pup dosing started, therefore the Cohort 1 and 2-4 animals could be taken together as they were up to this timepoint treated equally. However, due to the termination of the high dose group after excessive toxicity seen in cohort 1 pups, there were less animals available for high dose investigations. Therefore, the high dose group at PND 10 consists only of 3 instead of 10 animals /sex, while the PND4 groups were determined by the number of superplus animals.

Table 5.7.1-34: Concentration of BAS 310 I in brain and body of pups

Maternal Dose [mg/kg bw/day]	Sex of pups	PND4			PND10		
		Number of pups	Body [mg/kg]	Brain [mg/kg]	Number of pups	Body [mg/kg]	Brain [mg/kg]
0 Group 0	♂	3	nd	0.000	10	nd	0.000
	♀	4	nd	0.000	10	nd	0.000
0.5 Group 1	♂	6	0.011	0.000	10	0.007	0.000

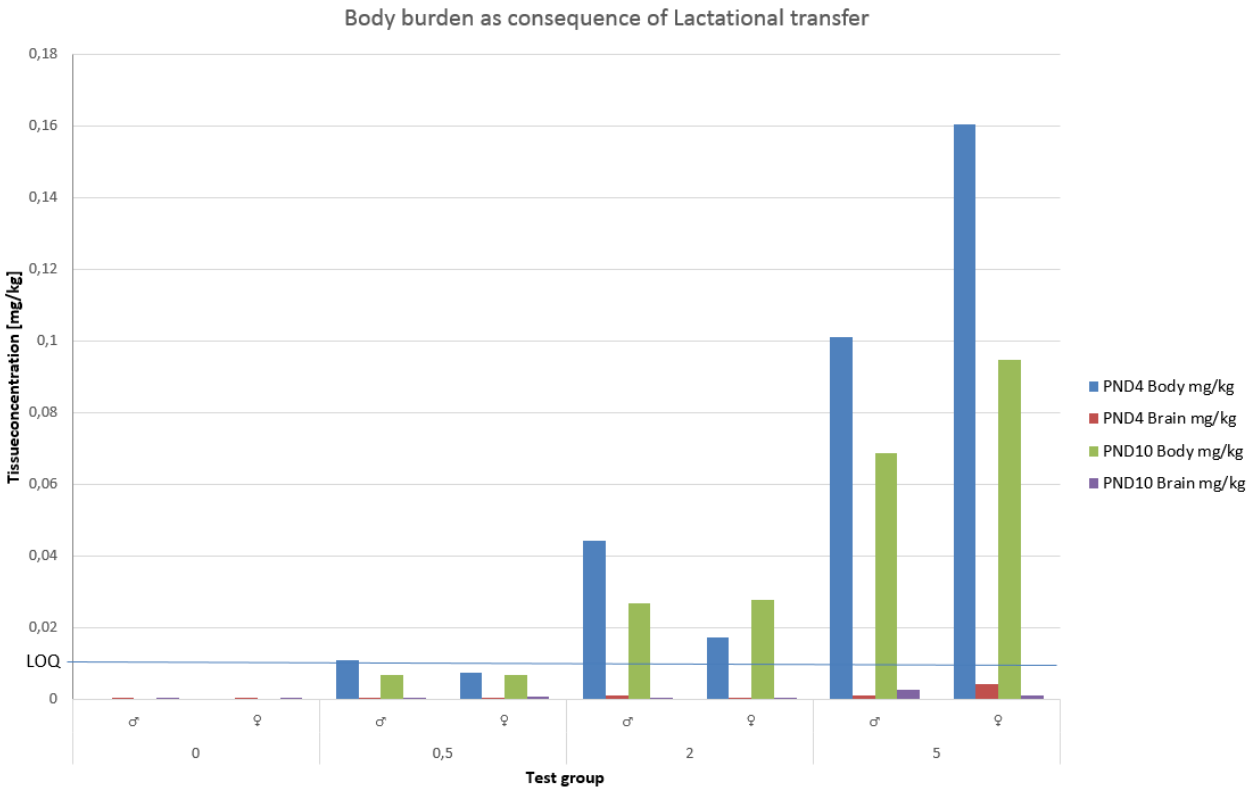
5 Group 3	♂	2	0.101	0.001	3	0.069	0.003
	♀	1	0.160	0.004	3	0.095	0.001

nd: < LOD; LOD= 0.0002 mg/kg for rodent brain and 0.001 mg/kg for rodent body ; LOQ=0.01 mg/kg;

Figure 5.7.1-7: Concentration of BAS 310 I in brain and body of pups PND 4 and PND 10



Alpha-cypermethrin was found at PND 4 and PND10 mainly in the **carcass specimen**.
The mean body burden at **PND4** was with one exception (low dose female pups) above the limit of quantification (10 µg/kg) and increased with the maternal dose up to values of 101/160 µg/kg tissue in the high dose pups without inducing any effects in the pups. The value of 160 µg/kg tissue is however based on one single female carcass and was with regard to the more conservative male value not used for NOAEL calculations. On **PND 10**, 2 days after the last maternal dosing, the carcass still exhibited measureable amounts of alpha-cypermethrin. The body burden with 69 / 95 µg/kg tissue in high dose males and female pups, respectively, was slightly lower compared to the level found at PND 4 (about 60-70%). The low dose pups on PND10 exhibited 7 µg/kg tissue, which is a value slightly below the LOQ used for LOAEL calculations below.

Only very low amounts of alpha-cypermethrin were detectable in **brain specimens** at PND 4 and PND 10, all below the limit of quantification, with the highest value found in the single high dose female pup at PND 4 with 4 µg/kg tissue.

No detectable isomerization of alpha-cypermethrin (Cis II) could be observed in all specimens.

A bioavailability of 46% is considered in order to transfer these body burden values into an external dose. The PND 4 level detected in high dose male pups (101 µg/kg tissue) is considered the systemic no observed effect levels, while the PND 10 low dose level (7 µg/kg tissue) was sufficient to lead to acute neurotoxicity in 21.2% of the pups after direct treatment with 250 µg/kg free alphacypermethrin in CMC. This ends up in a NOAEL of 220 µg/kg bw (101µg/kg / 46%) and a LOAEL of 265 µg/kg bw (7 µg/kg / 46% +250 µg/kg).

The robustness of this LOAEL calculation is questioned by the one high dose female at PND 4 which was free of any clinical signs despite a body burden of 160 µg alphacypermethrin/kg tissue, representing an calculated external dose of 350 µg/kg bw (160 µg/kg / 0,46). However, it demonstrates the conservatism of this calculation considering the Dose Response. Only 21.2% of the pups showed slight clinical signs, thereof 10.6% slight tremors after administration of 250 µg/kg bw to the low dose pups (external dose: 265 µg/kg bw). 44-45 % of the pups showed effects after administration of 250 µg/kg bw to the mid dose animals or 500 µg/kg bw to the low dose animals (external dose: 308-515 µg/kg bw). The effects increased with regard to the incidence of tremors from 29 % to 41% and in regard to severity from up to moderate to up to severe tremors. 100 % of the animals showed clinical sings in the mid dose after administration of 2000 µg/kg bw (external dose: 2059 µg/kg bw). Therefore, the high dose female pup with an systemic dose of 160 µg/kg bw (external dose of 350 µg/kg bw) can be considered as one animal of the 50% less sensitive animals in this dose range (perhaps due to a higher amount of fat or due to a higher metabolic capacity).

In summary, the detection of alpha-cypermethrin in pups at PND 4 and 10 prior to any direct contact to alpha-cypermethrin is the proof of lactational transfer. The availability of alpha-cypermethrin in pups 48 hours after the last maternal dosing indicates a rather slow elimination at least from some tissue compartments and a still ongoing lactational transfer. The extremely low amounts in brain correlates with the lack of adverse effects in pups during lactational exposure. Converting the systemic dose based on the bioavailability of 46% ends up in a NOAEL of 220 µg/kg bw (101µg/kg / 46%) while the LOAEL is 265 µg/kg bw (7 µg/kg / 46% +250 µg/kg).

III. CONCLUSIONS

The administration of BAS 310 I (alpha-cypermethrin) to pregnant female Wistar rats by oral gavage from gestation day (GD) 6 to postnatal day (PND) 8 at doses of 0.5, 2, or 5 mg/kg bw induced no clinical or neurotoxic signs in the dams or the offspring. The analytical processing of the pups on PND 4 and PND 10 confirmed that the body burden of the pups correlates with the maternal dose and that a two-days treatment-free interval between the last exposure of dams and the first exposure of offspring is obviously not enough to eliminate the test substance completely.

However, lactational exposure up to PND 10 did not induce adverse effects in pups up to a maternal dose of 5 mg/kg bw, which resulted in a pup body burden of up to 101/160 µg/kg bw on PND4 in male and female pups, respectively. Considering PND4 as at least similar sensitive as later time points based on the increasing metabolic capacity, 101 µg/kg bw can be considered as systemic NOAEL.

Substance administration via direct pup dosing from PND10 to PND21 induced acute treatment-related mortality at 2 and 5 mg/kg bw/day, while signs of neurotoxicity were observed down to 0.5 mg/kg bw/day (tremors, tonic-clonic convulsions, excessive grooming and twitching, together with hypothermia, lateral position and vocalization at the mid and high dose).
A 50% reduction of the pup dose to 0.25 mg/kg bw/day while remaining the pre-treatment of dams until PND 8 at 0.5 and 2 mg/kg bw/day resulted in similar signs of neurotoxicity, however reduced in incidence and severity.

Apart from the clinical symptoms, pup development was rather unaffected in the surviving animals in all test groups as shown by unchanged pup weights/weight gain and absence of necropsy findings. Motor activity measurements did not reveal any significant treatment-related changes. Regarding neuropathology, no treatment-related findings in brain weights, gross pathology and length and width measurements of the brain were found in any of the groups.

The analytical investigations of PND 10 pups after the two-days treatment-free interval still revealed a body burden of 7 µg/kg bw in low dose pups. This internal body burden, corrected for bioavailability of 46%, together with the external dose of 250 µg/kg bw can be considered as **calculated LOAEL at 265 µg/kg bw/day**. Considering the internal dose of 101 µg/kg bw at PND4 as systemic NOAEL, and corrected for bioavailability of 46% ends up in a **calculated NOAEL of 220 µg/kg bw**.

Altogether, the data show that there occurs exposure via milk which still leads to measureable amounts of alphacypermethrin after a two-days treatment-free interval. However, direct pup dosing is an extreme method for pre-weanling pups, and of no direct relevance to the overall human or ecotoxicological risk assessment. Therefore, as discussed in the "Reasoning for the appropriateness of dietary DNT studies for alpha-cypermethrin" (see above) this study is not used for the human risk assessment but the dietary developmental neurotoxicity study with zeta-cypermethrin is considered adequate.

Report: CA 5.7.1/4
[redacted] 1994a
WL85871 (Fastac): A 90 day dietary toxicity study in the rat - Volume 1 of 3
AL-425-007
Guidelines: none
GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Executive Summary

The aim of this study was to determine the effect of WL85871 (BAS 310 I) on neurotoxicity to rats after administration via the diet for 90 days. The test substance was administered to groups of 15 male and female Crl:CD(SD)BR rats at dietary concentrations of 50, 250, and 500 ppm. Clinical signs were recorded daily and functional observational battery (FOB) and measurements of motor activity, forelimb and hindlimb gripstrength and hindlimb landing footsplay were made before the start of dosing and in weeks 4, 8 and 13. At termination, 10 animals underwent a conventional necropsy and the remaining animals were subjected to whole body glutaraldehyde perfusion fixation in order to investigate central and peripheral nervous system tissues, eyes and muscle.
The administration of WL85871 at a dietary level of 500 ppm had an adverse effect on bodyweight gain and food intake and was associated with minor reductions in red blood cell parameters (RBC, HGB, HCT) and plasma total protein. Although relative liver weight was increased in males treated at this dose level, there was no microscopic evidence of hepatotoxicity and this response was therefore considered to be an adaptive one. Relative kidney weight was also slightly increased, but again, in the absence of morphological changes, this response and the not strictly dose related increases in blood urea nitrogen seen at 500 ppm and lower dose levels, were considered to be of no toxicological significance. At 250 ppm possible effects of treatment were limited to a transient reduction in food intake and slight reductions in red blood cell parameters and total plasma protein. No treatment related alterations in neurobehavior (FOB), motor activity or hind limb landing foot splay were observed. Lower forelimb grip strength in females fed 500 ppm at week 4 was considered attributed to a lower body weight.
In conclusion, the no observed effect level for neurotoxicity was concluded to be 500 ppm whereas that for general toxicity was 50 ppm WL85871.

(DocID 1994/7001607)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin (FASTAC, WL85871)

Description:	solid (powder) / white
Lot/Batch #:	02156
Purity:	95.6%
Stability of test compound:	The test substance was stable in the diet at room temperature for a period of 4 weeks, as determined in an earlier experiment with FASTAC (Report SBTR.93.002).

2. Vehicle and/or positive control: None

3. Test animals:

Species:	Rats
Strain:	Crl:CD(SD)BR
Sex:	Male and female
Age:	35 days (start of administration)
Weight at dosing (mean):	males: 208 g females: 173 g
Source:	Charles River Laboratories, Manston, UK
Acclimation period:	7 days
Diet:	pelleted diet (Rat and Mouse Maintenance Diet No. 1, Expanded, Special Diets Services)
Water:	water, ad libitum
Housing:	in groups (5 animals per cage) during acclimatization and single housing during the rest of the study period in grid bottomed polypropylene cages (pattern RB3R North Kent Plastics, Dartford)
Environmental conditions:	
Temperature:	19 - 23°C
Humidity:	45 - 70%
Air changes:	NA
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 06-May-1993 - 23-Mar-1994
(In life dates: 06/07-May-1993 (start of administration)
to 05/13-Aug-1993 (necropsy)

2. Animal assignment and treatment:
WL85871 was administered to groups of 15 male and 15 female mice at dietary concentrations of 0, 50, 250 and 500 ppm for at least 90 days.

3. Test substance preparation and analysis:
The test substance is applied via the oral route in the diet. Three batches of the substance preparations were prepared before the beginning of the study and twice during the study to assure stability of test substance preparations. For each dietary concentration separately, a weighed amount of test article was dissolved in acetone and poured over 50 kg of diet. The diet was mixed for 2 minutes in a high speed mixer. Control diet had an equivalent volume of acetone added (5 mL/kg) and was also mixed for 2 minutes.
The stability of the test substance in the diet at room temperature for a period of weeks was determined in an earlier experiment. Homogeneity was re-confirmed by taking sextuplicate samples in a semi-random manner from each of the first batch of treated diets prepared.
Concentrations of treated diets were assessed on a second occasion in this study by analysis of duplicate samples of the third batch of diets prepared. For control diet, a single sample of each of the first and third batches prepared was analysed. HPLC (all concentrations) and GC (50 and 250 ppm) analysis were performed.

4. Statistics:
For neurobehavioural responses the analyses were designed to identify effects in treated groups, relative to controls, taking into account changes over time. Analyses were first applied to test for differences in profiles over time for the various treatment groups. Secondly, differences between groups at each of the time points were tested so as to ascertain when in the experiment differences first became statistically significant.
Means and standard deviations (S.D.) of each test group were calculated for several parameters.

C. METHODS

1. Observations:
The animals were examined for clinical changes, for abnormal pattern of behavior and for gross deviations in food and water consumption and mortality twice daily on working days and once daily on weekends and public holidays.

2. Body weight:
Body weight was determined before the start of the administration period and and thereafter in weekly intervals.

3. Food consumption and compound intake:
Individual food consumption was determined in weekly intervals.

4. Clinical assessment of neurotoxicity:
Observations and activity measurements were made before the start of dosing and again in weeks 4, 8 and 13. These observations were applied to 10 male and 10 female animals and consisted of a Functional Observation battery (FOB), forelimb and hindlimb grip strength, a hindlimb landing footsplay test, and a motor activity assessment.

5. Hematology and clinical chemistry:
Blood samples were taken by orbital-sinus puncture from 10 males and 10 females of each group in week 12 after an overnight fasting.
The following hematological and clinical chemistry parameters were determined for all animals:

Hematology:		
Red blood cells	*White blood cells*	*Clotting Potential*
✓ Erythrocyte count (RBC)	✓ Total leukocyte count (WBC)	NA
✓ Hemoglobin (Hb)	✓ Differential blood count	
✓ Hematocrit (Hct)	✓ Platelet count (PLT)	
✓ Mean corp. volume (MCV)	✓ Plateletcrit	
✓ Mean corp. hemoglobin (MCH)	✓ Mean platelet volume	
✓ Mean corp. Hb. conc. (MCHC)	✓ Platelet distribution width	
✓ Reticulocytes (RET)		
✓ Red cell distribution width		

Clinical chemistry:		
Electrolytes	*Metabolites and Proteins*	*Enzymes:*
✓ Calcium	✓ Albumin	✓ Alanine aminotransferase (ALT)
✓ Chloride	✓ Albumin/globulin ratio	✓ Aspartate aminotransferase (AST)
✓ Phosphorus (inorganic)	✓ Bile acids	✓ Alkaline phosphatase (ALP)
✓ Potassium	✓ Bilirubin (total)	✓ γ-glutamyl transpeptidase (γ-GT)
✓ Sodium	✓ Cholesterol	
	✓ Creatinine	
	✓ Glucose	
	✓ Protein (total)	
	✓ Triglycerides	
	✓ Urea nitrogen	

6. Urinalysis:
For urinalysis the individual animals were transferred to metabolism cages during week 11 and urine was collected overnight from 10 males and females. No food or water was supplied during urine collection.

The following quantitative or semi-quantitative parameters were determined for all animals:

Urinalysis					
	Quantitative parameters:		*Semi quantitative parameters*		
✓	Urine volume	✓	Bilirubin	✓	Protein
✓	Osmolality	✓	Hemoglobin	✓	pH-value
		✓	Color and turbidity	✓	Urobilinogen
		✓	Glucose	✓	Sediment (microscopical exam.)
		✓	Ketones		

7. Ophthalmoscopy:
Both eyes of all animals were examined before the start of treatment and those of all control and high dose animals were examined again in week 12. Examinations were made using an indirect ophthalmoscope after instillation of a mydriatic agent.

8. Sacrifice and pathology:
Five males and five females of each group were assigned to while body perfusion fixation and the remainder were assigned to conventional necropsy and immersion fixation.

Perfusion fixation:
The animals were fasted before necropsy. They were each anaesthetized with an intraperitoneal injection of sodium pentobarbitone and the heart was exposed to allow incision in both the left ventricle and right atrium. Heparinised saline was first infused into the aorta via the left ventricle, followed by infusion of 2.5% buffered glutaraldehyde. There was no macroscopic examination of internal organs or organ weighing in these animals. Carcasses of perfused animals were stored refrigerated for at least one hour before the tissues listed overleaf were dissected into fresh fixative.

The following organs were examined after perfusion fixation:
- Brain (6 transverse slices taken between the frontal lobes and the medulla oblongata)
- Eyes with optic nerve (left and right)
- Sciatic nerve (right and left*, proximal and distal tibial, longitudinal and transverse)
- Skeletal muscle (left, femoral, gastrocnemius with sural)
- Spinal cord (cervical, thoracic and lumbar, longitudinal and transverse)
- Spinal ganglia (cervical and lumbar)
- Sural nerve (right and left, longitudinal and transverse)

*taken for resin embedding

Immersion fixation:
The animals were fasted before necropsy. They were a lethal intraperitoneal injection of sodium pentobarbitone, weighed and then exsanguinated.
Post mortem examination included physical examination of the external body surface, all orifices, carcass, cranial cavity, thoracic, abdominal and pelvic cavities with their associated organs and tissues and the neck with its associated organs and tissues.

The following organs were sampled, weighed and examined histopathologically after immersion fixation:

Pathology:

The following organs were collected (column C), weighed (W) and examined histopathologically (H, ✓: all groups, #: control and top dose).

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSES

Diets were found to be homogenous and of correct concentrations (within 7% of nominal).

B. OBSERVATIONS

1. Clinical signs of toxicity

No treatment related clinical signs of toxicity were reported. Those signs that were observed, generally minor skin lesions such as occasional scabs or fur thinning, were seen in control animals also and represented typical background clinical signs.

2. Mortality

No animal died during the study.

C. BODY WEIGHT AND BODY WEIGHT GAIN

Bodyweight gain was not adversely affected in either sex treated at 50 ppm or, in males treated at 250 ppm. Females dosed at 250 ppm showed marginally lower weight gain than controls from the onset of treatment. Over the last few weeks of the study the difference in bodyweight between these groups became statistically significant, with females treated at 250 ppm having a terminal bodyweight 7% lower than the control value.

A more marked reduction in weight gain was noted in both sexes at 500 ppm. In the first week of treatment bodyweights were 13% and 10% lower in males and females, respectively, when compared to the control. Weights were consistently lower than the control values throughout the study with reductions in mean final bodyweight of 8% and 9% for males and females, respectively.

Table 5.7.1-35: Mean body weight of rats administered WL85871 for 90 days

	Males				Females			
Dose level [ppm]	0	50	250	500	0	50	250	500
Body weight [g]								
- Week 0	207.6	213.6	210.3	208.9	173.1	177.7	174.0	172.0
- Week 1	265.8	270.0	254.8	231.7** (87.2%)	203.4	207.8	195.4	182,2** (89.6%)
- Week 7	456.8	466.6	454.6	412.2** (90.2%)	293.8	300.2	278.9	262.1** (89.2%)
- Week 9	488.0	496.8	488.3	446.1** (91.4%)	311.3	317.1	291.5* (93.6%)	277.9** (89.3%)
- Week 13	519.3	530.3	523.4	477.0** (91.9%)	323.0	332.8	301.3	293.2** (90.8%)

* = p≤0.05; ** = p≤0.01

D. FOOD CONSUMPTION AND COMPOUND INTAKE

No differences of food intake were observed in the 50 ppm group. At 250 ppm a moderate reduction of food intake of 16% and 11% during the first week was observed, but was similar to control in the following weeks. This pattern was considered consistent with the introduction of an unpalatable diet. At 500 ppm a moderate reduction of food intake of during the first week was observed, lasting until the last 2 (males) or 4 (females) weeks of the study, when differences were marginal and no longer statistically significant.

The calculated average test article intake at 50, 250 and 500 ppm over the study was 3.7, 17.9 and 36.1 mg/kg bw/day for males, and 4.2, 21 and 42 mg/kg bw/day for females.

E. CLINICAL ASSESSMENT OF NEUROTOXICITY

The FOB yielded no statistically significant alterations in animals given 50 ppm. Isolated observations (number of defaecations, faecal consistency, startle/"click" response, number of pools of urine passed) were seen, but were not dose related, not consistent for both sexes, and were only significant at the $p<0.05$ level, and given the large number of observations made, may have arisen purely by chance. It is concluded, therefore, that there were no toxicologically significant neurobehavioural differences manifested in the FOB.

Furthermore, there were no alterations in forelimb or hindlimb gripstrength for either sex at 50 or 250 ppm or for males dosed at 500 ppm. Females of the high dose group had significantly lower forelimb grip strength at week 4, but was normal at week 8 and 13. Overall hindlimb grip strength was also lower ($p<0.05$) than that of the controls but, when individual occasions were considered, no significant differences were apparent. Since females dosed at 500 ppm were lighter animals than controls, this initial difference in grip strength may simply have reflected the reduced bodyweight gain.

There were no significant intergroup differences in hindlimb landing footsplay.

No treatment related alterations in motor activity were observed. Although the total number of movements made by females treated with 50 ppm was significantly lower than the control values at week 4, the lack of dose response relationship as well as the between occasion variation in control values suggested that this single significant finding was fortuitous.

Table 5.7.1-36: Mean total number of movements for females

	Week number			
Concentration [ppm]	-1	4	8	13
0	140	361	377	266
50	191	242*	341	255
250	220	443	492	329
500	197	323	299	343

F. BLOOD ANALYSIS

1. Hematology

Males treated at 250 or 500 ppm had marginally (≤5%) lower mean red blood cell counts, haemoglobin concentrations and haematocrits than control animals. These minor differences, although statistically significant, were not associated with abnormal cell types or with alterations in other haematological parameters.

The minimal (3%) reduction in haemoglobin concentration alone in males dosed at 50 ppm was considered to be of no toxicological significance.

There were no significant haematological variations in female groups.

Table 5.7.1-37: Group mean haematology data in male animals at week 13

Concentration [ppm]	RBC [10E12/L]	HGB [g/dL]	HCT [%]
0	9.03	16.4	50.8
50	8.69	15.9*	49.4
250	8.63*	15.8*	48.9*
500	8.56*	15.7**	48.8*

* = p≤0.05; ** = p≤0.01

2. Clinical chemistry findings

With the exception of a raised mean blood urea nitrogen level in females, there were no treatment related alterations in blood chemistry at the 50 ppm dietary level.

In males dosed at 250 or 500 ppm and in all treated female groups, blood urea nitrogen levels were moderately raised, but not in a dose related manner. There was no accompanying increase in plasma creatinine or significant changes in concentration of plasma electrolytes to suggest a nephrotoxic effect. Furthermore, there were no histopathological changes related to treatment. The increases in BUN were therefore considered not related to treatment.

The plasma total protein levels of females (250 and 500 ppm) were slightly (≤6%) but significantly lower than the control values. For high dose females this reduction may ave reflected the lowered food intake of this group.

The apparent decreases in plasma bilirubin (females) and alkaline phosphatase (males) noted at 500 ppm were considered to be of no diagnostic significance since a rise in these markers is normally sought as evidence of hepatic dysfunction.

Table 5.7.1-38: Group mean clinical chemistry data at week 13

Concentration [ppm]	Urea N. [mmol/L]	Protein [g/L]	Calcium [mmol/L]	Alkaline phosphatase [I.U./L]	Bilirubin [µmol/L]
Males					
0	5.2	65.1	2.70	248	2.0
50	5.4	64.8	2.72	259	2.0
250	6.0*	65.2	2.72	212	2.0
500	5.8*	64.4	2.72	212	2.0
Females					
0	5.4	71.1#	2.80	175	1.9
50	7.0**	68.2	2.77	147	2.0
250	7.0**	67.5*	2.79	175	1.8
500	6.9**	67.0*	2.72*	139	1.5*

* = p≤0.05

** = p≤0.01; # = F19 excluded for statistical reasons

G. URINALYSIS

There were no toxicologically significant changes in urine cellularity or composition. Slight variations in urinary osmolality, pH and glucose in females of the 50 ppm dose group were considered spontaneous as no dose response was observed.
An apparent fall in urinary triple phosphates in males dosed 500 ppm was of doubtful toxicological significance.

H. Ophthalmoscopy

There were no ocular changes or abnormalities that could be attributed to treatment.

I. NECROPSY

1. Organ weight

When compared to the control group (set to 100%) the mean absolute weights were not significantly changed (see Table 5.7.1-39). Expressed as a percentage of bodyweight, a number of organs of animals treated at 500 ppm showed significant weight variations. The increase in relative testes weight noted in males was considered to be a direct effect of growth retardation. Not attributable to reduced bodyweight were the slight increases in relative kidney weight and the moderate increase in relative liver weight in males.

Table 5.7.1-39: Group mean relative organ weight data (% of bodyweight) for those organs showing statistically significant variations.

Concentration [ppm]	Brain	Kidneys	Liver	Adrenals	Testes
Males					
0	0.44	0.61	2.56	0.011	0.71
50	0.43	0.60	2.69	0.010	0.73
250	0.44	0.61	2.72	0.012	0.72
500	0.48*	0.67*	2.91**	0.012*	0.83*
Females					
0	0.67	0.64	2.79	0.024	-
50	0.64	0.62	2.72	0.023	-
250	0.72	0.65	2.88	0.027	-
500	0.72	0.69*	2.97	0.027	-

* = p≤0.05; ** = p≤0.01

2. Gross lesions

No macroscopic lesions were recorded.

3. Histopathology

There were no microscopic changes to account for the increased liver and relative kidney weights at 500 ppm and no evidence of neuropathological changes or other microscopic changes associated with the test substance.

III. CONCLUSIONS

The administration of WL85871 induced no treatment-related changes in FOB, motor activity or hindlimb landing foosplay. Changes in forelimb gripstrength were considered related to lower body weight of the 500 ppm females. Macroscopic and microscopic investigations revealed no neuropathological lesions at any dose.
At a dietary level of 500 ppm bodyweight gain and food intake were reduced and minor reductions in red blood cell parameters (RBC, HGB, HCT) in both sexes and total plasma protein was slightly lowered. Although relative liver and kidney weight was increased in males treated at this dose level, there was no microscopic evidence of morphological changes, both these responses were considered adaptive and not of toxicological relevance. Moderately but not strictly dose related increases in blood urea nitrogen seen in all females and in males at 250 and 500 ppm were considered to be not treatment related based on missing accompanying increases in parameters that suggest a nephrotoxic effect.
At 250 ppm effects of treatment were limited to a transient reduction in food intake and slight reductions in red blood cell parameters and total plasma protein.

The no observed effect level for neurotoxicity was concluded to be 500 ppm, which is equivalent to 36.1 and 42 mg/kg bw/day for males and females, respectively, whereas that for general toxicity was concluded to be 50 ppm WL85871 (3.7 / 4.2 mg/kg bw for males / females, respectively).

CA 5.7.2 Delayed polyneuropathy studies

As alpha-cypermethrin does not belong to a chemical class suspected to induce delayed neuropathies, no study is considered to be necessary and thus no further study was conducted.

EU Dossier update (Oktober 2015) contains data which were not present at the dossier submission in February 2015, these are: For the studies discussed in chapter CA 5.8.1/37 & 38 concerning the metabolite M310I011 (PBA) separate analytical reports (Doc ID 2015/1029517, Doc ID 2015/1003984 & 2015/1032402) are now available and the data are highlighted.

CA 5.8 Other Toxicological Studies

CA 5.8.1 Toxicity studies of metabolites

Studies evaluated in the monograph of the rapporteur member state Belgium of September 1999:

No toxicological studies were presented for metabolites during the former European assessment of alpha-cypermethrin. Thus, the following conclusion was drawn in the Annex I listing of alpha-cypermethrin:

Other toxicological studies	No data – not required

Meanwhile further insights into behavior of alpha-cypermethrin in plants, animals and in the environment has been obtained and thus several metabolites were identified which require further consideration (see section KCA 6.9).

With regard to potential toxicological relevance the following metabolites were considered and are addressed in this dossier section.

Table 5.8.1-1: Alpha-cypermethrin metabolites considered for potential toxicological relevance assessment

Metabolite	Structure	Reason for relevance assessment
Group A) Hydroxylated derivatives of alpha-cypermethrin and their conjugates		
M310I017 Reg. No. 6002320 WL 48394 (cis) CL 194198		Livestock metabolite (goat) Plant metabolite (wheat, cabbage)
M310I015		Livestock metabolite (goat)
M310I021		Livestock metabolite (goat)

Metabolite	Structure	Reason for relevance assessment
Group B) Conjugated hydroxy-(3-Phenoxy-phenyl)acetonitrils		
M310I005		Plant metabolite (lettuce)
M310I007		Plant metabolite (lettuce)
Group C) DCVA, hydroxylated DCVA and their conjugates		
M310I001 Reg. No. 4080830 CAS number: 59042-49-8 DCVA DCVC acid Cis-DVA CL 912554 CL 194198 (cis)		Livestock metabolite (goat, hen) Plant metabolite (wheat)
M310I003		Livestock metabolite (goat, hen)
M310I004		Livestock metabolite (goat)
M310I008		Plant metabolite (lettuce)
M310I009		Plant metabolite (lettuce)
Group D) Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates		
M310I024 CAS-No. 13826-35-2 Reg.No. 207323 PBAlc WL 40673 CL 206128		Plant metabolite (wheat, cabbage)
M310I006		Plant metabolite (lettuce)
M310I018 Reg.No. 4080665 CAS-No. 39515-51-0 EC No. 254-487-1 PBAld		Plant metabolite (wheat)

Metabolite	Structure	Reason for relevance assessment
WL 42049 CL 206969 3-PBAD 3-PBAD III m-PBAD CPBT		
M310I011 Reg. No. 130213 CAS No.: 3739-38-6 3-phenoxybenzoic acid PBA m-PB acid 3-PB acid WL 44607 CL 206128		Livestock metabolite (goat, hen) Plant metabolite (wheat)
M310I010 Reg. No. 4108084 N-(3-phenoxybenzoyl)glycine 3PBA glycine WL 46194 CL 117585		Livestock metabolite (goat) Plant metabolite (wheat)
M310I026 Reg.No. 4110960 3-phenoxy-benzoyl glutamic acid CL 949371		Plant metabolite (wheat)
M310I013 WL 46114 CL 213336		Plant metabolite (cabbage)
M310I025 Reg.Nr.4110493		Plant metabolite (wheat)
Group E) 3-Hydroxybenzoic acid		
M310I019 CAS-No. 99-06-9 EC-No. 202-726-5 FL-no. 08.132		Livestock metabolite (hen)

Thus, the conclusion for relevant endpoints for the current re-registration was drawn as follows:

Other toxicological studies (SANCO/11802 data point 5.8)

Toxicity studies of metabolites as referred to in the introduction	**Group A) Hydroxylated derivatives of alpha-cypermethrin and their conjugates:** **M310I017 (**livestock and plant metabolite) – by weight of evidence not genotoxic in vitro and in vivo – due to close structural relationship covered by the toxicological database of alpha-cypermethrin. Conclusion: **not toxicologically relevant** based on grouping approach **M310I015 (**livestock metabolite) – by weight of evidence not genotoxic in vitro and in vivo and exposure – below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. – due to close structural relationship covered by the toxicological database of alpha-cypermethrin. Conclusion: **not toxicologically relevant** based on grouping approach **M310I021 (**livestock metabolite) – by weight of evidence not genotoxic in vitro and in vivo based on data reported for the aglycone – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. – due to close structural relationship covered by the toxicological database of alpha-cypermethrin. Conclusion: **not toxicologically relevant** based on grouping approach **Group B) Conjugated hydroxy-(3-Phenoxy-phenyl)acetonitrils:** **M310I005** (plant metabolite) – not genotoxic in vitro based on data reported for the aglycone – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. Conclusion: **not toxicologically relevant** based on grouping approach

	M310I007 (plant metabolite) - not genotoxic in vitro based on data reported for the aglycone - exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. Conclusion: **not toxicologically relevant** based on grouping approach **Group C) DCVA, hydroxylated DCVA and their conjugates** **M310I001** (livestock & plant metabolite) - rat metabolite of alpha-cypermethrin. - not genotoxic in vitro - exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. - no relevant endocrine activity Conclusion: covered by toxicological testing of parent and **not toxicological relevant** based on grouping approach. **M310I004** (livestock metabolite) - major rat metabolite of alpha-cypermethrin. - not genotoxic in vitro based on data reported for the aglycone DCVA and for alpha-cypermethrin. - exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. Conclusion: covered by toxicological testing of parent and **not toxicological relevant** based on grouping approach. **M310I008** (plant metabolite) - expected cleavage to aglycone in mammalian gastrointestinal tract. - not genotoxic in vitro based on data reported for the aglycone DCVA and for alpha-cypermethrin. - exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. Conclusion: covered by toxicological testing of parent and **not toxicological relevant** based on grouping approach.

	M310I009 (plant metabolite) - expected cleavage to aglycone in mammalian gastrointestinal tract. - not genotoxic in vitro based on data reported for the aglycone DCVA and for alpha-cypermethrin. - exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. Conclusion: covered by toxicological testing of parent and **not toxicological relevant** based on grouping approach. **Group D) Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates** **M310I024** (plant metabolite) – not genotoxic in vitro (reported in DAR of lambda-cyhalothrin – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. – no relevant endocrine activity Conclusion: **not toxicological relevant** **M310I006** (plant metabolite) – not genotoxic in vitro based on data for the aglycone M310I024 – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compound. – no relevant endocrine activity based on data for the aglycone M310I024 Conclusion: **not toxicological relevant** **M310I018** (plant metabolite) – not genotoxic in vitro and in vivo – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. – Moderate acute toxicity – Not irritating to skin and eye – May be a skin sensitizer – 90-day rat study: NOEL 50 mg/kg bw/day, increased liver and kidney weights attributed to metabolic activation considered not adverse – no relevant endocrine activity Conclusion: **not toxicological relevant**

	M310I011 (livestock and plant metabolite) – by weight of evidence not genotoxic – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. – moderate acute toxicity – not acutely neurotoxic – no relevant endocrine activity Conclusion: **not toxicological relevant** **M310I010** (livestock and plant metabolite) – by weight of evidence not genotoxic based on data for the unconjugated derivatives – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. – moderatel acute toxicity based on data for the unconjugated derivatives – not acutely neurotoxic based on data for the unconjugated derivatives – no relevant endocrine activity based on data for the unconjugated derivatives Conclusion: **not toxicological relevant** based on grouping approach. **M310I026** (plant metabolite) – by weight of evidence not genotoxic based on data for the unconjugated derivatives – exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. – moderatel acute toxicity based on data for the unconjugated derivatives – not acutely neurotoxic based on data for the unconjugated derivatives – no relevant endocrine activity based on data for the unconjugated derivatives Conclusion: **not toxicological relevant** based on grouping approach.

M310I013 & M310I025 (plant metabolite)
- by weight of evidence not genotoxic based on data for non-hydroxylated M310I011
- exposure below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds.
- moderatel acute toxicity based on data for non-hydroxylated M310I011
- not acutely neurotoxic based on data non-hydroxylated M310I011
- no relevant endocrine activity based on data non-hydroxylated M310I011
- conjugates of hydroxylated M310I013 are rat metabolites

Conclusion: **not toxicological relevant** based on grouping approach

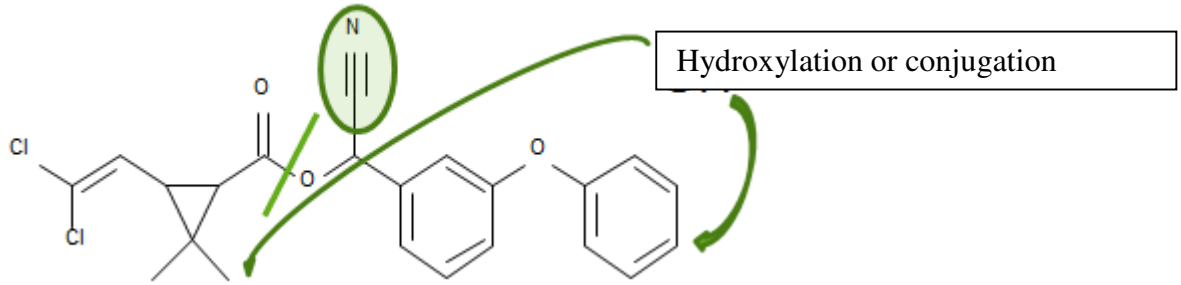
Group E) 3-Hydroxybenzoic acid

M310I019 (livestock)
- Evaluated by EFSA as food flavor being a Cramer Class 1 compound with low toxicity: TTC 1800 µg/person/day
- Toxicological evaluation by EFSA based on grouping approach:
  - By weight of evidence no safety concern with respect to genotoxicity
  - Acute toxicity, repeated dose toxicity data and developmental / reproductive toxicity data of group candidate and supporting substances were consistent with the group evaluation
- Low acute toxicity
- No relevant estrogenic activity

Conclusion: **not toxicological relevant** based on EFSA grouping approach for food flavours.

Strategy to assess metabolite relevance – grouping approach

Although there are differences in the metabolic pathways in plants, animals and the environment the formed degradation products are the same or closely related. Metabolism of alpha-cypermethrin in plants and animals is mostly characterized by cleavage of the cyano-group, ester cleavage and subsequent hydroxylation and/or conjugation of the degradates.



In order to avoid unnecessary animal testing and use of resources a grouping approach was setup.

The grouping proposal takes into account:

A) Chemical similarity,
B) Coverage by mammalian toxicity studies conducted with alpha-cypermethrin or other cypermethrins
C) Information on chemical reactivity (structural alerts)

In a further step key structures were selected for toxicological relevance assessment within every metabolite group.

D) Selection of key structures for hazard assessment

A Chemical Similarity

With regard to evaluation of chemical similarity the general proposals given by e.g. by the EFSA Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment [EFSA Journal 2012;10(07):2799] were followed. The following general molecular modifications were considered to probably not cause higher toxicity of the metabolites:

- Simple demethylation of the ring or side chain
- Simple hydroxylation of the ring system without any cleavage of the ring
- Hydroxylation of another ring position
- Conjugation of metabolites with amino acids

Comparison was made to parent as well as to the grouped metabolites in order to select key metabolites for testing. In addition consideration of increased hydrophilicity and thus considered faster excretion of the grouped metabolites as compared to the tested key metabolites and/or parent was taken into account. Conjugates were considered as their aglycons/parent metabolites if cleavability could be assumed, (e.g. for O-glucosides)

Generally there is some overlap between functional groups covered by metabolites of different metabolite groups. Therefore on a case by case basis only one of the metabolites with this functional group was considered for testing and considered suitable to allow evaluation of the metabolite with the same functional group included in another group, where such consideration was taken into account this is indicated in the respective grouping evaluation.

B Coverage of metabolites of concern by mammalian toxicity studies

An overlap exists in the metabolism of alpha-cypermethrin or other cyppermethrins in animals, plants and soil. Thus general conclusions drawn from the animal metabolism of the cypermethrins as well as overlaps of metabolite structures were taken into consideration when grouping the metabolites with regard to human exposure from the food residues. It was considered whether either the metabolites under consideration or similar structures were formed in the metabolisms studies conducted in mammals.
Moreover, it is taken into consideration that metabolites after uptake in to the body could be transformed by known metabolic pathways into structures that have been identified in the mammalian metabolism studies conducted.

C Presence of Structural alerts - QSAR evaluation of metabolites

For all unconjugated metabolites identified with potential relevance, the presence for potential structural alerts was evaluated with different SAR/QSAR models. Models used, were OASIS TIMES, and VEGA. However, the QSAR predictions obtained are limited in reliability as most of the structures evaluated were not in the prediction domain. Thus, given the structural relationship of the metabolites evaluated inter alia and in relation to the parent molecule alpha-cypermethrin, the predicted alerts were compared to those for the parent and those metabolites were toxicological data were available in order to overcome the limitations of the predictions made.

OASIS TIMES

OASIS TIMES is a hybrid statistical and knowledge-based model for toxicity prediction. The Tissue Metabolism Simulator (TIMES), developed by LMC (Bourgas University, Bulgaria; http://oasis-lmc.org/) integrates on the same platform a metabolic simulator and QSAR models for predicting toxicity of selected metabolites. The metabolic simulator generates plausible metabolic maps from a comprehensive library of Dettenbiotransformations and abiotic reactions. It allows prioritization of chemicals according to toxicity of their metabolites. Of OASIS TIMES the prediction models for Ames test and in vitro chromosome aberration were considered and therefore predictivity is limited to these test systems only. The reports for the evaluations made are available under [KCA 5.8.1/1 2014/1289314] for Ames mutagenicity and [KCA 5.8.1/2 2014/1289315] for prediction of chromosomal aberration in vitro. Q(SAR) Model Reporting Formats (QMRF) for both endpoints are provided in [KCA 5.8.1/3 2013/1414242 and [KCA 5.8.1/4 2013/1414460.

The reactivity model describing interactions of chemicals with DNA is based on an alerting group approach. Only those toxicophores extracted from the training set having clear interpretation for the molecular mechanism causing the ultimate effect included in the model. The mechanistic interrelation between alerts and related parametric ranges generalizing the effect of the rest of the molecules on the alert is also considered. The structural component of the model is based on the structural similarity between chemicals in the training set which were correctly predicted by the model. The structural neighborhood of atom-centered fragments is used to determine this similarity. The training set consists of 1514 chemicals for Ames and 808 chemicals for chromosomal aberration.

The derived model is combined with metabolic simulator TIMES used for predicting metabolic activation of chemicals with the S9 mix. The metabolic simulator is trained to reproduce documented maps for mammalian liver metabolism for 261 chemicals. Parent chemicals and each of the generated metabolites are submitted to a battery of models to screen for a general effect and mutagenicity mechanisms. Thus, chemicals are predicted to be mutagenic as parents only, parents and metabolites, and metabolites only. Mutagenicity could be due to the parent chemical only or as a result of its metabolic activation (i.e., the parent is inactive but it is transformed to a mutagenic metabolite), or both parent structure and metabolites could be mutagenic.

This OASIS QSAR system is also included in the OECD Toolbox (but not in combination with TIMES), in order to make use of (Q)SAR approaches also in the assessment of chemicals under REACH (http://www.oecd.org/chemicalsafety/risk-assessment/). The BASF-internal version has the advantage that it is capable to consider metabolic transformation.

VEGA

Using the VEGA platform, access to a series of QSAR (quantitative structure-activity relationship) models for regulatory purposes was obtained. Of the models offered by VEGA [http://www.vega-qsar.eu/] only the two independent statistical prediction models for mutagenicity (Ames) were selected. The data obtained for alpha-cypermethrin and its metabolite can be found in [see KCA 5.8.1/5 2014/1289317], [see KCA 5.8.1/6 2014/1319956] and [see KCA 5.8.1/7 2014/1320536]. This report includes all three models used (CAESAR, SarPy, Toxtree). CAESAR makes predictions based on the comparison of the structure of interest to the CAESAR database of mutagenicity data of substances in the structure database. A score is provided for the match of the structures, and the mutagenicity data of the closest related substances compared to the structure of interest. Consequently, if a structure is not adequately presented in the database, the prediction is only of very limited validity.

The second algorithm SarPy searches for isolated structural alerts of substructures in the molecule. Again this is based on the mutagenicity data provided in the structure database. Only predictivity for mutagenicity based on the Ames test was generated.

The third algorithm Toxtree is based on Benigni-Bossa Mutagenicity rules of structural alerts for mutagenicity. It works as a decision tree for estimating carcinogenicity, based on a list of structural alerts (SAs). The SAs for mutagenicity are molecular functional groups or substructures known to be linked to the mutagenic activity of chemicals. As one or more SAs embedded in a molecular structure are recognised, the system flags the potential mutagen of the chemical. The model goes through a first step in which a set of 12 SAs related to mutagenicty is checked The SAs are the following (SA numbers refer to the original Benigni/Bossa study):
- SA 1: Acyl halides
- SA 6: Propiolactones or propiosultones
- SA 11: Simple aldehyde
- SA 12: Quinones
- SA 13: Hydrazine
- SA 14: Aliphatic azo and azoxy
- SA 16: alkyl carbamate and thiocarbamate
- SA 18: Polycyclic Aromatic Hydrocarbons
- SA 21: alkyl and aryl N-nitroso groups
- SA 22: Azide and triazene groups
- SA 25: Aromatic nitroso group
- SA 28bis: Aromatic mono- and dialkylamine
- SA 29: Aromatic diazo

CAVEAT on reliability of QSAR modules implied

With regard to the QSAR evaluations as implied in OECD TIMES and in VEGA it should be noted that for nearly all analysis the algorithm reported an out of structural domain error. Each of this QSAR models is build on a set of chemicals that forms its chemical domain, space or applicability domain. That means that the prediction is best if a structure of interest is represented in the original baseline dataset. Substances outside of the dataset are evaluated in comparison to the chemical space, and only in case that the chemical space adequately covers all structural elements or the queried structure, the prediction is considered to be adequately covered by experimental data. Predictions outside of the applicability domain have far lower predictability. In addition all mentioned QSAR models check for structural alerts, like those identified by the Benigni-Bossa rules that have been implicated in mutagenic actions.

As a consequence, the predictivity is solely based on the proposed DNA-interaction via the structural alert, not (VEGA) or not appropriately (OASIS TIMES) taking into account possible functional group interaction and stereochemical hindrance. It is well established that structure elements have to be evaluated within the context of a structure.

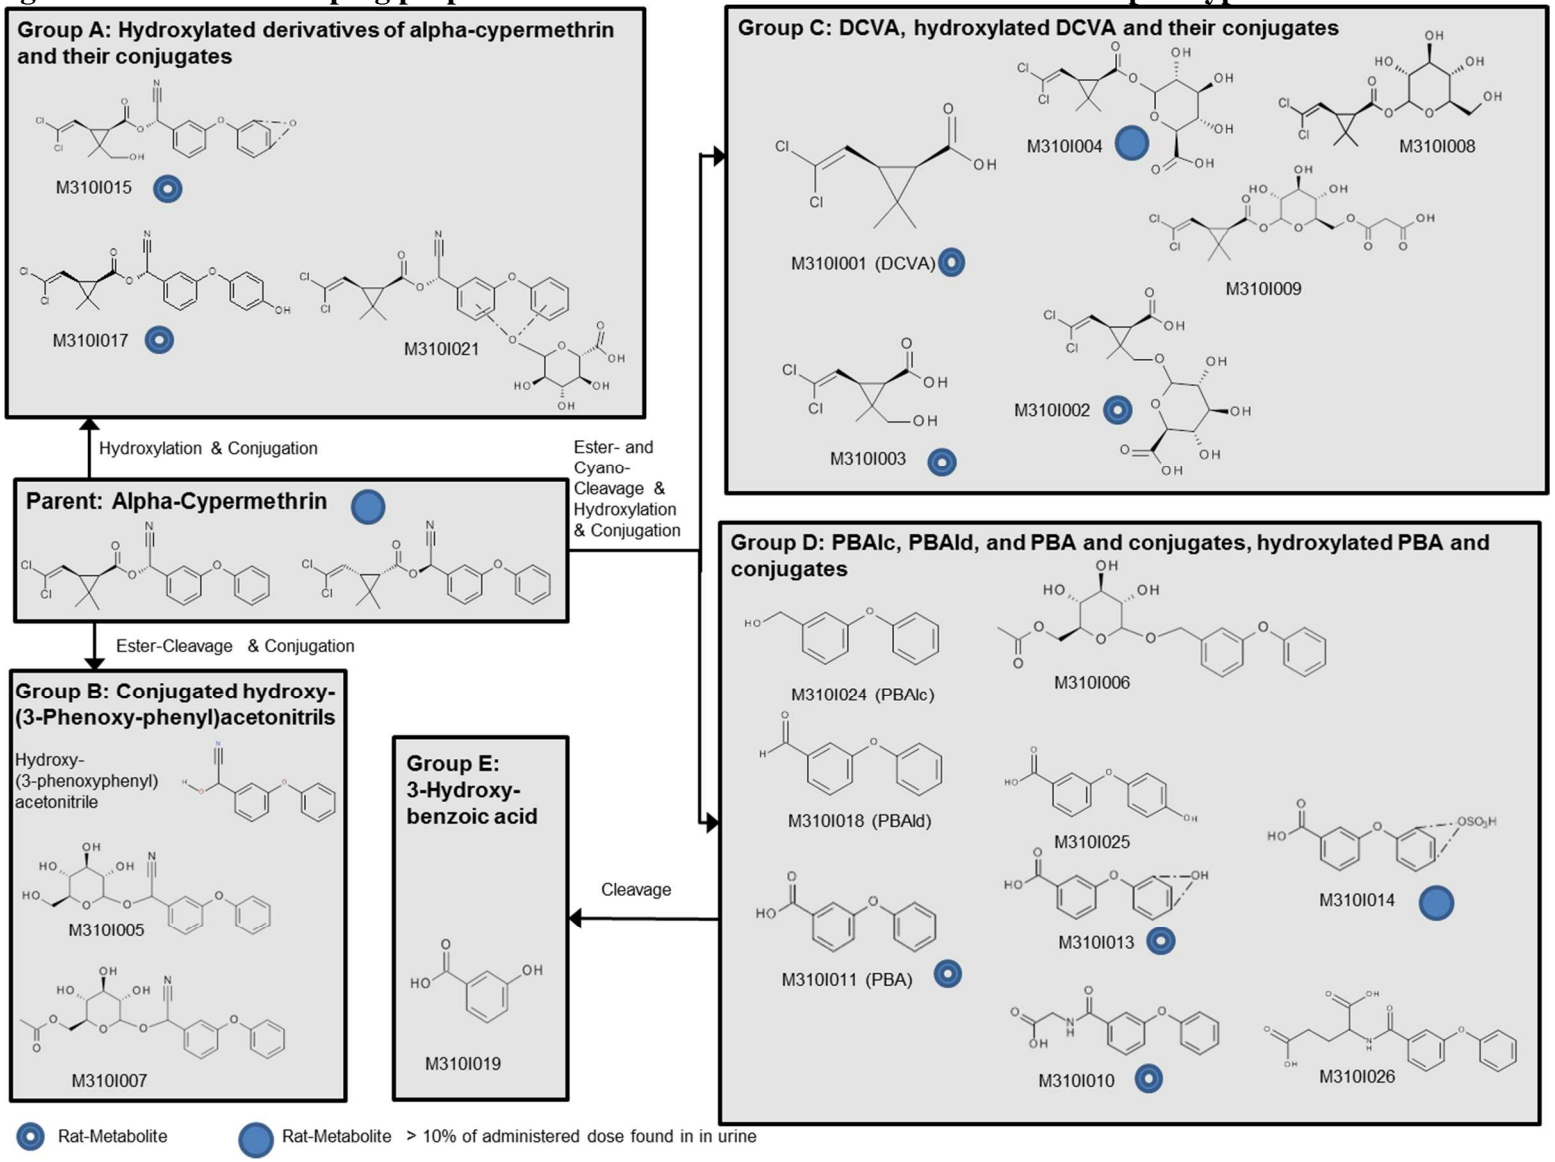
In general, the predictivity of various QSAR models for genotoxicity equilvalent to the Ames test has been considered to be reasonable accurate. Predictivity rates expressed as accuracy and specificity are usually >80%. This is in particular true, if information from more than one QSAR model is combined.

QSAR models for chromosome aberration however are far less well established. One of the underlying limitations is that typical in vitro assays for chromosome aberration, like chromosome aberration in V79 cells or the in vitro micronucleus assay have false discovery rates of approximately 30%. This means that three out of ten molecules are falsely categorized. In addition a high number of in vitro positive substances are negative in adequate in vivo assays. The later is often a function of the underlying mode of action and the kinetic behavior of a substance. Both are not adequately covered by QSAR predictions.

Predictions for chromosome damage were performed with OASIS Times. The prediction model used in the OECD toolbox is similar to that of OASIS Times, with the major difference being the different underlying database of reference compounds and the combination with the metabolism generator in OASIS Times.

The VEGA system - with the CAESAR SarPy and ToxTree modules used - only predicts bacterial mutagenicity.

Figure 5.8.1-1: Grouping proposal for relevance assessment of metabolites of alpha-cypermethrin



The groups were named as follows:

A) Hydroxylated derivatives of alpha-cypermethrin and their conjugates
B) Conjugated hydroxy-(3-Phenoxy-phenyl)acetonitrils
C) DCVA, hydroxylated DCVA and their conjugates
D) Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates
E) 3-Hydroxybenzoic acid

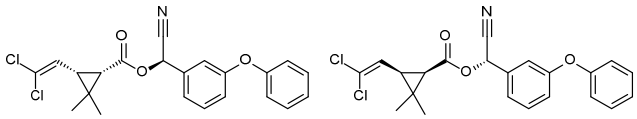
D Selection of key structures hazard assessment and toxicological testing strategy

As proposed by the EFSA scientific opinion on evaluation of the toxicological relevance of pesticide metabolites for dietary risk assessment the predicted exposure levels are taken into consideration. The proposed threshold levels for chronic exposure are 0.0025 µg/kg bw/day for potentially genotoxic compounds, 0.3 for presumably neurotoxic, and 1.5 µg/kg bw/day for non-genotoxic Cramer Class III compounds. These threshold levels are based on the threshold of toxicological concern (TTC) concept.
Furthermore an acute exposure assessment was considered necessary since an ARfD has been allocated for alpha-cypermethrin. The corresponding TTC value for acute exposure would be 5 µg/kg bw/day.

The TTC-concept is an approach to assess whether chemical structures, for which no or only limited information on the toxicological profile is available, are of concern. The TTC [Cramer et al. 1978a, [see KCA 5.8.1/8 1978/1001324]; Kroes et al. 2004a, [see KCA 5.8.1/9 2004/1036074]; Munro et al 1996a, [see KCA 5.8.1/10 1996/1005180] has meanwhile been considered in the EU e.g. for the evaluation of chemicals under the REACH regulation [*ECHA (2012) Guidance on information requirements and chemical safety assessment Chapter R.8: Characterisation of dose [concentration]-response for human health*] and has been employed or considered for the evaluation of food flavourings [*EFSA, 2010e. Guidance on the data required for the risk assessment of flavourings to be used in or on foods. European Food Safety Authority. The EFSA Journal 8(6): 1623. Available at: http://www.efsa.europa.eu/en/efsajournal/doc/1623.pdf*] or pesticidal degradation products by EFSA [*EFSA, 2012b. Scientific Opinion: Exploring options for providing preliminary advice about possible human health risks based on the concept of Threshold of Toxicological Concern (TTC). European Food Safety Authority (EFSA) Scientific Committee, Parma, Italy; EFSA Journal, 10(7), 2750 and EFSA, 2012a. Scientific opinion on evaluation of the toxicological relevance of pesticide metabolites for dietary risk assessment. EFSA Panel on Plant Protection Products and their Residues (PPR), European Food Safety Authority (EFSA), Parma, Italy; EFSA Journal, 10(07), 2799*].

The available toxicological database for metabolites of each group will be discussed in the following paragraphs. This starts with an assessment of the QSAR predictions of the parent alpha-cypermethrin and is followed by the evaluation of metabolites structured by groups as indicated above.

Alpha-cypermethrin (other denominators: BAS 310 I, Reg. No 4078193, WL 85871, CL 900049



Alpha-cypermethrin is a racemate of (S)-cyano-3-phenoxybenzyl (1R,3R) 3 (2,2 dichlorovinyl)-2,2 dimethylcyclopropanecarboxylate and (R)-cyano-3 phenoxybenzyl (1S,3S) 3 (2,2 dichlorovinyl)-2,2 dimethylcyclopropanecarboxylate. With regard to QSAR evaluations the stereoisomeric properties could not be taken into account as the available tools do not allow evaluation of stereoselective effects.

Weight of evidence approach for genotoxicity of alpha-cypermethrin QSAR prediction in relation to toxicological testing

For alpha-cypermethrin an extensive database on in vitro and in vivo genotoxicity studies is available. There is no evidence for mutagenicity or clastogenicity in any of the conducted studies in bacterial, fungal or mammalian cells in vitro or in mammals in vivo. Given the lacking evidence in vitro and in vivo the identified alerts for chromosomal for alpha-cypermethrin in OASIS Times is not considered of relevance.

Hydroxylated derivatives of alpha-cypermethrin and their conjugates

Definition of group A: Hydroxylated derivatives of alpha-cypermethrin and their conjugates

For the group of hydroxylated derivatives of alpha cypermethrin, the following molecules were taken into consideration:

M310I017
M310I015
M310I021

All three structures are closely related to alpha-cypermethrin. M310I017 is deviating by hydroxylation of the terminal aromatic benzyl-ring and for M310I015 by an additional hydroxylation of the dimethylcyclopropane moiety. M310I021 is a glucone conjugate of a ring-hydroylated derivative.

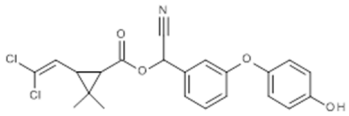
Note: for M310I017 the para-location of the hydroxylation group was confirmed. Although an exact position of the ring hydroxylation of M310I015 was not possible due to insufficient metabolite amounts recovered, it is reasonable to assume that thre ring-hydroxylation is located in the para-position also for the following reasons:

1. It is plausible that M310I015 is a metabolite successor of M310I017
2. Given the molecular structure a para-position of the terminal ring is more probable
3. Metabolic investigations on M310I011 the Phenoxy benzoic acid moity of alpha-cypermethrin in several mammalian species identified the para-hydroxylation of the phenoxy-ring i.e. 4-hydroxylation as the major metabolic pathway thereof [see CA 5.8.1/39 CY-905-031]. A ortho-position hydroxylation instead was not reported.

With regard to the glycone M310I021 again the most plausible position of the glycone conjugate is the para-position of the terminal ring for the same criteria as stated above.

Evaluation of group A members: Hydroxylated derivatives of alpha-cypermethrin and their conjugates

M310I017 (other denominators: Reg.No. 6002320; 4'hydroxy-alpha-cypermethrin, CL 194198, WL 48394 (cis), WL 48393 (trans))



M310I017 is a metabolite found in rats (small amounts in feces) and in livestock animals (goat).

QSAR Predicitions on M310I017

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 2 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]

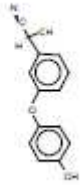
There were **no** Ames mutagenicity alerts for M310I017 or in-silico generated metabolites although several metabolites and Phenyl-OH itself had a structural alert info "Haloalkenes with Electron-Withdrawing Groups". In all cases the structures were out of domain.

For in-vitro chromosome aberration the prediction for M310I017 was **positive** (out of domain) referring to the structural alert info "Cyanohydrines". One out of 15 in-silico metabolites was predicted positive (in domain) with the alert info 'Cyanohydrines' (undetermined model reliability). The remaining in-silico metabolites were negative (out of domain).

Figure 5.8.1-2: Metabolite of M310I017 predicted positive for in-vitro chromosome aberration

2.3

Metabolite



Predicted CA with S9	in vitro CA positive
Predicted Mechanism	Interactions with topoisomerases / proteins
Alert info	Cyanohydrines
ModelReliability	Undetermined (0 <n< 10)
Total Domain	In domain

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 2 of report [see KCA 5.8.1/5 2014/1289317]]

M310I017 is out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Two of the six most similar molecules had positive experimental data. The other four had the prediction non-mutagen, which was experimentally confirmed. The concordance of the total underlying database was moderate (0.667) and thus is not very robust. Both the two positive (similarity 0.857 to 0.934) and the four negative molecules (similarity 0.785 to 0.976) has a reasonably similar structure to M310I017. Therefore, the chemical space does adequately cover the structure of M310I017.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 2 of report [see KCA 5.8.1/5 2014/1289317]]

M310I017 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Two of the six most similar molecules had positive experimental data. The other four had the prediction non-mutagen, which was experimentally confirmed. The concordance of the total underlying database was moderate (0.667) and thus is not very robust. Both the two positive (similarity 0.857 to 0.934) and the four negative molecules (similarity 0.785 to 0.976) has a reasonably similar structure to M310I017. Therefore, the chemical space does adequately cover the structure of M310I017.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 2 of report [see KCA 5.8.1/5 2014/1289317]]

M310I017 is in the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. None of the six most similar molecules had positive experimental data. The concordance of the total underlying database was high (1.0) and thus is very robust. All six negative molecules (similarity 0.757 to 0.94) have a reasonably similar structure to Phenyl-OH. Therefore, the chemical space does adequately cover the structure of Phenyl-OH.

Conclusion on QSAR evaluations of M310I017
The QSAR evaluation of M310I017 is of moderate reliability and by weight of evidence there was no conclusive alert for genotoxicity.

The similar structure to alpha-cypermethrin and the identical structural alert from QSAR applications result in the same assessment as for alpha-cypermethrin. The in vivo and in vitro data of alpha-cypermethrin indicates no chromosome damaging potential. Furthermore, in vitro data exist for the metabolite Hydroxy-(3-Phenoxy-phenyl)acetonitrile, (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 184-187) that demonstrate no chromosome damaging potential. Therefore, the positive prediction for CA of M310I017 (OASIS Times), based on study results obtained for the parent alpha-cypermethrin and the metabolite Hydroxy-(3-Phenoxy-phenyl)acetonitrile is not reflecting the toxicological database and is rejected.

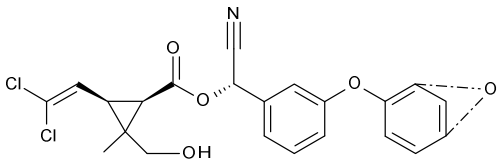
Toxicological evaluation of M310I017

No conclusive alerts for gentotoxicity were identified by the QSAR evaluation conducted. Furthermore, hydroxylation of the ring system without any cleavage of the ring is often identified as probably not causing higher toxicity of metabolites (EFSA, 2012; 10(07):2799). Thus, given the close structural relationship to the parent molecule alpha-cypermethrin and the lacking concordance with study results obtained for the metabolite Hydroxy-(3-Phenoxy-phenyl)acetonitrile, M310I017 is by weight of evidence not considered to be genotoxic and not considered to be more toxic than the parent molecule.

With regard to chronic consumer exposure the TTC concept for a non-genotoxic, but presumably neurotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. However, for acute exposure the TTC-threshold of 5 µg/kg bw/day would be exceeded (189% of TTC value) [see Table in section MCA 6.9]. As stated above M10I017 due to its close structural relationship to alpha-cypermethrin is considered to be covered by the toxicological database for the parent. Consequently the ARfD of 0.04 mg/kg bw/day is considered to apply also for M310I017 which will clearly cover the estimated acute dietary exposure level.

M310I017 is considered to be not genotoxic based on the available information and due to the close structural relationship to alpha-cypermethrin covered by the toxicological evaluation of the parent molecule. Therefore, M310I017 is considered to be **not toxicologically relevant**.

M310I015



M310I015 is a metabolite found in trace amounts in rats and in livestock animals (goat)

a. QSAR Predicitions on M310I015

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 3 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]
There were **no** Ames mutagenicity alerts for M310I015 or in-silico generated metabolites although several metabolites and Dihydroxy alpha-cypermethrin itself had a structural alert info "Haloalkenes with Electron-Withdrawing Groups". In all cases the structures were out of domain. For in-vitro chromosome aberration the prediction for Dihydroxy alpha-cypermethrin was **positive** (out of domain) referring to the structural alert info "Cyanohydrines". One out of 19 in-silico metabolites was predicted positive (in domain) with the alert info 'Cyanohydrines' (undetermined model reliability). The remaining in-silico metabolites were negative (out of domain).

Figure 5.8.1-3: Metabolite of M310I015 predicted positive for in-vitro chromosome aberration

3.3

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 3 of report [see KCA 5.8.1/5 2014/1289317]]
M310I015 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Two of the six most similar molecules had positive experimental data. The other four had the prediction non-mutagen, which was experimentally confirmed. The concordance of the total underlying database was moderate (0.668) and thus is not very robust. Both the two positive (similarity 0.837 to 0.911) and the four negative molecules (similarity 0.769 to 0.953) has a reasonably similar structure to Dihydroxy alpha-cypermethrin. Therefore, the chemical space does adequately cover the structure of Dihydroxy alpha-cypermethrin.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 3 of report [see KCA 5.8.1/5 2014/1289317]]
M310I015 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Two of the six most similar molecules had positive experimental data. The other four had the prediction non-mutagen, which was experimentally confirmed. The concordance of the total underlying database was moderate (0.668) and thus is not very robust. Both the two positive (similarity 0.837 to 0.911) and the four negative molecules (similarity 0.769 to 0.953) has a reasonably similar structure to Dihydroxy alpha-cypermethrin. Therefore, the chemical space does adequately cover the structure of Dihydroxy alpha-cypermethrin.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 3 of report [see KCA 5.8.1/5 2014/1289317]]
M310I015 is in the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. None of the six most similar molecules had positive experimental data. The concordance of the total underlying database was high (1.0) and thus is very robust. All six negative molecules (similarity 0.752 to 0.919) have a reasonably similar structure to Dihydroxy alpha-cypermethrin. Therefore, the chemical space does adequately cover the structure of Dihydroxy alpha-cypermethrin.

Conclusion on QSAR evaluations of M310I015
The QSAR evaluation of M310I017 is of moderate reliability and by weight of evidence there was no conclusive alert for genotoxicity.

The similar structure to alpha-cypermethrin and the identical structural alert from QSAR applications result in the same assessment as for alpha-cypermethrin. The in vivo and in vitro data of alpha-cypermethrin indicates no chromosome damaging potential. Furthermore, in vitro data exist for the metabolite (Hydroxy-(3-Phenoxy-phenyl)acetonitrile, see [see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 184-187] that demonstrate no chromosome damaging potential. Therefore, the positive prediction for chromosomal aberration of M310I015 (OASIS Times), based on study results obtained for the parent alpha-cypermethrin and the metabolite Hydroxy-(3-Phenoxy-phenyl)acetonitrile (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 184-187) is not reflecting the toxicological database and is rejected.

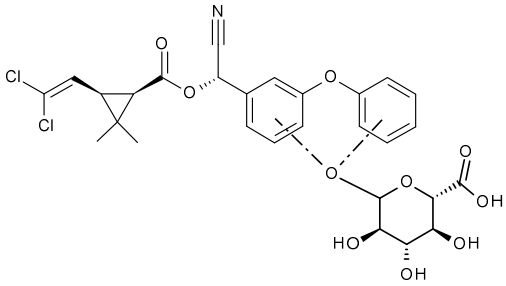
Toxicological evaluation of M310I015

No conclusive alerts for gentotoxicity were identified by the QSAR evaluation conducted. Furthermore, hydroxylation of the ring system without any cleavage of the ring is often identified as probably not causing higher toxicity of metabolites (EFSA, 2012; 10(07):2799). Thus, given the close structural relationship to the parent molecule alpha-cypermethrin and the lacking concordance with study results obtained for the metabolite Hydroxy-(3-Phenoxy-phenyl)acetonitrile (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 184-187), M310I015 is by weight of evidence not considered to be genotoxic and not considered to be more toxic than the parent molecule.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated chronic exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I015 is considered to be not genotoxic based on the available information and the estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. M10I015 due to its close structural relationship to alpha-cypermethrin is considered to be covered by the toxicological database for the parent. Therefore, M310I015 is considered to be **not toxicologically relevant**.

M310I021



M310I021 is a metabolite found in in livestock animals (goat)

a. Toxicological evaluation of M310I021

After dietary uptake M310I021 is expected to be cleaved to the aglycone M310I017. No conclusive alerts for gentotoxicity were identified by the QSAR evaluation conducted for the agylcone M310I017. Furthermore, hydroxylation of the ring system without any cleavage of the ring is often identified as probably not causing higher toxicity of metabolites (EFSA, 2012; 10(07):2799). Thus, given the close structural relationship to the parent molecule alpha-cypermethrin and the lacking concordance with study results obtained for the metabolite Hydroxy-(3-Phenoxy-phenyl)acetonitrile (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 184-187), M310I015 is by weight of evidence not considered to be genotoxic and not considered to be more toxic than the parent molecule.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I021 is considered to be not genotoxic based on the available information and the estimated exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. M10I021 due to its close structural relationship to alpha-cypermethrin is considered to be covered by the toxicological database for the parent. Therefore, M310I021 is considered to be **not toxicologically relevant**.

Toxicological relevance Group A: Hydroxylated derivatives of alpha-cypermethrin and their conjugates

M310I017, M310I015 and M310I021 are structurally closely related to the parent compound alpha-cypermethrin. The additional hydrolations are not considered to increase the toxicity profile of these metabolites when compared to alpha-cypermethrin as oxygen-bridged sugar conjugation which is considerd to be immediately cleaved when uptaken via the diet. The conducted evaluation on QSAR regarding genotoxicity alerts did not identify any alert considered of relevance. The only alert determined namely the structural alert for cyanohydines was also identified for parent alpha-cypermethrin and for the metabolite Hydroxy-(3-Phenoxy-phenyl)acetonitrile (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 184-187) for which both the available toxicological database did not provide any evidence to support this alert. Furthermore, hydroxylation of the ring system without any cleavage of the ring is often identified as probably not causing higher toxicity of metabolites (EFSA, 2012; 10(07):2799). Consequently the metabolites of that group are considered to be covered by the toxicological database of the parent molecule alpha-cypermethrin.

In conclusion the metabolites of the group A are by weight of evidence not considered to be genotoxic or neurotoxic and and are not considered to be toxicological relevant.

Conjugated Hydroxy-(3-Phenoxy-phenyl)acetonitrils

I. Definition of group B: Conjugated Hydroxy-(3-Phenoxy-phenyl)acetonitrils

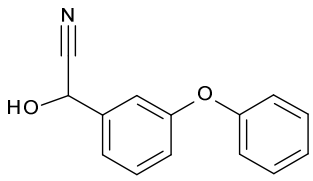
This group comprises Hydroxy-(3-Phenoxy-phenyl)acetonitrile and its glucoside-conjugates:

Hydroxy-(3-phenoxyphenyl)acetonitrile
M310I005
M310I007

It is expected that these oxygen-bridged sugar conjugates are immediately cleaved to the aglycone when orally uptaken into the body. Consequently the toxicological evaluation is based on the aglycone itself.

II. Evaluation of group B members: Conjugated Hydroxy-(3-Phenoxy-phenyl)acetonitrils

Hydroxy-(3-Phenoxy-phenyl)acetonitrile (other denominators: Aglycon of M310I005 or M310I007; CAS-Nos for stereoisomers: 71962-66-8, 61826-76-4 and 39515-47-4)



Hydroxy-(3-Phenoxy-phenyl)acetonitrile is the aglycon of the above mentioned metabolites M310I005 or M310I007 and a presumed intermediate in the plant metabolism. It was not determined in the rat metabolism studies.

a. QSAR Predicitions on Hydroxy-(3-Phenoxy-phenyl)acetonitrile

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 7 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]
There were **no** Ames mutagenicity alerts for Hydroxy-(3-Phenoxy-phenyl)acetonitrile or in-silico generated metabolites and no structural alerts were reported. In all cases the structures were out of domain.
For in-vitro chromosome aberration the prediction for Hydroxy-(3-Phenoxy-phenyl)acetonitrile was **positive** (out of domain, model reliability undetermined (0<n<10)) referring to the structural alert info “Cyanohydrines”. None of 5 in-silico metabolites were predicted positive (out of domain).

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 7 of report [see KCA 5.8.1/5 2014/1289317]]
Hydroxy-(3-Phenoxy-phenyl)acetonitrile was out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Four of the six most similar molecules had positive experimental data. Each one of the remaining metabolites had the prediction "mutagen" and "non-mutagen". Experimental values were negative for both of them. The concordance of the total underlying database was low (0.0) and thus is not very robust. Both the positive (similarity 0.833 to 0.856) and the negative molecules (similarity 0.836 to 0.843) have a reasonably similar structure to Hydroxy-(3-Phenoxy-phenyl)acetonitrile. Therefore, the chemical space does adequately cover the structure of Hydroxy-(3-Phenoxy-phenyl)acetonitrile.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 7 of report [see KCA 5.8.1/5 2014/1289317]]
Hydroxy-(3-Phenoxy-phenyl)acetonitrile is out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The same metabolites as reported in the CAESAR model were also used in the SarPy model yielding the same results.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 7 of report [see KCA 5.8.1/5 2014/1289317]]
Hydroxy-(3-Phenoxy-phenyl)acetonitrile could be out of the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. One of the six most similar molecules had positive experimental data. The concordance of the total underlying database was low (0.496) and thus is not very robust. All six molecules (similarity 0.801 to 0.831) have a reasonably similar structure to Hydroxy-(3-Phenoxy-phenyl)acetonitrile. Therefore, the chemical space does adequately cover the structure of Hydroxy-(3-Phenoxy-phenyl)acetonitrile.

Conclusion on QSAR evaluations of Hydroxy-(3-Phenoxy-phenyl)acetonitrile
For Hydroxy-(3-Phenoxy-phenyl)acetonitrile results from an Ames test, Mouse Lymphoma Assay, and an in vitro chromosome aberration assay were reported in the DAR for lambda-cyhalothrin (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, pages 133-134 and pages 179-187). Based on the negative results for chromosome aberration in in vitro studies the positive prediction using OASIS TIMES QSAR model is rejected.

Toxicological studies on Hydroxy-(3-Phenoxy-phenyl)acetonitrile

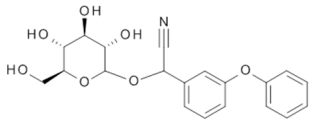
Toxicity of Hydroxy-(3-Phenoxy-phenyl)acetonitrile was assessed in the course of the renewal of lambda-cyhalothrin (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, pages 133-134 and pages 179-187). The acute oral toxicity in rats (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, pages 133-134) was >300 and < 2000 mg/kg bw. An in vitro genotoxicity package consisting of an Ames test, a mouse lymphoma assay and an in vitro chromosome aberration study gave no evidence for genotoxicity neither without nor with metabolic activation (see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, pages 179-187).

Toxicological evaluation of Hydroxy-(3-Phenoxy-phenyl)acetonitrile

The QSAR evaluation of Hydroxy-(3-Phenoxy-phenyl)acetonitrile is of moderate reliability and by weight of evidence there was no conclusive alert for genotoxicity. The lacking genotoxicity is supported by a datapackage on in vitro genotoxicity. Furthermore the acute toxicity study conducted showed only a moderate toxicity in comparison to alpha-cypermethrin.

In conclusion, Hydroxy-(3-Phenoxy-phenyl)acetonitrile is considered to be **not toxicologically relevant**.

M310I005



M310I005 is a plant metabolite found in lettuce.

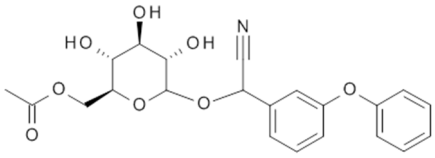
a. Toxicological evaluation of M310I005

Based on the toxicological evaluation of the aglycone of M310I005 - Hydroxy-(3-Phenoxy-phenyl)acetonitrile above – M310I005 is considered not to be genotoxic and is considered to be acutely less toxic than alpha-cypermethrin.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I005 is considered to be not genotoxic based on the available information and the estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. In conclusion M310I005 is considered to be **not toxicologically relevant**.

M310I007



M310I007 is also found as a plant metabolite in lettuce.

a. Toxicological evaluation of M310I007

Based on the toxicological evaluation of the aglycone Hydroxy-(3-Phenoxy-phenyl)acetonitrile above M310I007 is considered not to be genotoxic and and is considered to be acutely less toxic than alpha-cypermethrin.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I007 is considered to be not genotoxic based on the available information and the estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. In conclusion M310I005 is considered to be **not toxicologically relevant**.

Toxicological relevance Group B: Conjugated Hydroxy-(3-Phenoxy-phenyl)aceto-nitrils

It is expected that these oxygen-bridged sugar conjugates M310I005 and M310I007 are immediately cleaved to the aglycone Hydroxy-(3-Phenoxy-phenyl)aceto-nitrils when orally uptaken by mammalians. By weight of evidence there was no conclusive alert for genotoxicity for Hydroxy-(3-Phenoxy-phenyl)aceto-nitril. The lacking evidence is supported by toxicological data published within the evaluation of the Draft Renewal Assessement Report of Lambda-cyhalothrin of RMS Sweden of February 2013, pages 179-187) showing that there is no genotoxic potential in vitro.

In conclusion the metabolites of the group B are by weight of evidence not considered to be genotoxic or neurotoxic. They are below the relevant thresholds of toxicological concern for acute and chronic dietary exposure and thus considered to be not toxicologically relevant.

DCVA, hydroxylated DCVA and their conjugates

I. Definition of group C: DCVA, hydroxylated DCVA and their conjugates

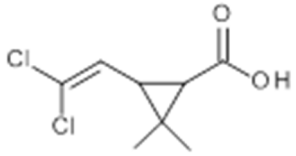
For the group of DCVA, hydroxylated DCVA and their conjugates, the following molecules were taken into consideration:

M310I001 (DCVA)
M310I004
M310I008
M310I009
M310I003 (hydroxylated DCVA)
M310I002

M310I004, M310I008 and M310I009 are o-bound glycosides of DCVA. These glycosides when uptaken into the human gastrointestinal tract via the diet are expected to be cleaved to the corresponding agylcone DCVA. Thus the glucones are considered to be covered by the toxicological evaluation of DCVA. M310I003 (hydroxylated DCVA) is structurally closely related to DCVA. With regard to the glycoside of hydroxylated DCVA (M310I002) same immediate cleavage is assumed as for the o-glycosides of DCVA. Moreover, M310I004 (the DCVA glucoronide), M310I003 (hydroxylated DCVA) and its glucuronid ester M310I002 are known rat metabolites, of which M310I004 is the major metabolite excreted via urine.

II. Evaluation of group C members: DCVA, hydroxylated DCVA and their conjugates

M310I001 (other denominators: DCVA, Reg.No. 4080830, CAS No.: 59042-49-8, 180011, CL 912554; Cis-Isomer: Cis-DVA, CL 194198 (cis), cis-3-(2,2-dichlorovinyl)2,2-dimethylcyclopropanecaroxylic acid; DCCA)



M310I001 is a metabolite found in rats, livestock animals (goat and hen) in wheat, in soil, water and sediment. This cis enantiomer respectively its racemate the trans-isomer (Trans-DCVA; CL 196336 (trans)) is also known as metabolite for e.g. Cypermethrin or Permethrin.

a. QSAR Predicitions on M310I001

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 5 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]
There were **no** Ames mutagenicity alerts for M310I001 or in-silico generated metabolites although several metabolites and M310I001 itself had a structural alert info "Haloalkenes with Electron-Withdrawing Groups". In all cases the structures were out of domain. The same holds true for the in vitro chromosome aberration.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 5 of report [see KCA 5.8.1/5 2014/1289317]]
M310I001 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The prediction is based on 6 molecules, of which all were predicted and actual 'non-mutagen'. The similarity to M310I001 of the molecules in the data set is moderate as indicated by similarity factors of 0.724 to 0.838.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 5 of report [see KCA 5.8.1/5 2014/1289317]]
M310I001 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The prediction is based on 6 molecules, of which 3 were predicted 'mutagen' but experimental values confirmed that all 6 were 'non-mutagen'. The similarity to M310I001 of the molecules in the data set is moderate as indicated by similarity factors of 0.724 to 0.838.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 5 of report [see KCA 5.8.1/5 2014/1289317]]
M310I001 is out of the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Two of the six most similar molecules were predicted 'mutagen' and three of them were positive referring to experimental data. The concordance of the total underlying database was moderate (0.518) and thus is not very robust. All six negative molecules (similarity 0.684 to 0.732) have a moderate similar structure to M310I001.

Conclusion on QSAR evaluations
No conclusive structural alert was identified for M310I001.

Toxicity studies on M310I001

Report:	CA 5.8.1/11 Hutson D.H., 1982a Pyrethroid intermediates (cis-DVA and CPBT): Short-term tests for genotoxic activity AL-470-006
Guidelines:	none
GLP:	yes
Remark:	only data for cis-DVA were considered from the study report

Executive Summary

S. typhimurium (strains TA98, TA 100, TA 1535, TA 1537 and TA 1538) and E. coli strain WP2 and WP2 uvrA were exposed to M310I001; batch: ST81-140, purity: 99%) using methanol as a solvent in the presence and absence of metabolic activation in two independent experiments. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment. The test substance was used at concentrations of 31.25, 62.5, 125, 250, 500, 1000, 2000, and 4000 µg/plate in the two main experiments. Bacteriotoxic effects were observed in a range finding test at concentrations higher than 4000 mg/plate. Precipitation of the test substance did occur at 1000 µg/plate and at higher concentrations. A biologically relevant increase in the number of revertant colonies was not noticed in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains in the presence of metabolic activation, thus demonstrating the sensitivity of the test system and the functionality of the S9 fraction. For Salmonella strains TA 1537, TA 1538, TA 98, and TA 100 no adequate control substances were used in the absence of metabolic activation. According to the results of the study M310I001 was not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.

(Doc ID 1982/7000919)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material	BPDU 7, CIS-DVA (Metabolite of BAS 310 I, Alpha-Cypermethrin)
Description:	Solid, beige, crystalline
Lot/Batch #:	ST81/140
Purity:	99%
Stability:	Infra-red spectroscopic fingerprint analysis revealed stability throughout the study period.
Solvent used:	Methanol

2. Control Materials:

Vehicle control: The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	Benzo(a)pyrene (BP)	Methanol	20 µg/plate
TA 1535	Sodium azide (NaN_3)	Methanol	5 µg/plate
TA 1537	Neutral red (NR)	Methanol	20 µg/plate
TA 1538	Benzo(a)pyrene (BP)	Methanol	20 µg/plate
TA 98	Benzo(a)pyrene (BP)	Methanol	20 µg/plate
WP2 uvrA	NQO	Methanol	20 µg/plate
WP2	NQO	Methanol	20 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	Benzo(a)pyrene (BP)	Methanol	20 µg/plate
TA 1535	Sodium azide (NaN_3)	Methanol	5 µg/plate
TA 1537	Neutral red (NR)	Methanol	20 µg/plate
TA 1538	Benzo(a)pyrene (BP)	Methanol	20 µg/plate
TA 98	Benzo(a)pyrene (BP)	Methanol	20 µg/plate
WP2 uvrA	NQO	Methanol	20 µg/plate
WP2	NQO	Methanol	20 µg/plate

3. Activation: Rat liver microsomal activation system (S9 fraction) was used for activation. No further details were given.

4. Test organisms: S. typhimurium strains: TA98, TA100, TA1535, TA1537, TA1538
E. coli: WP2, WP2 uvrA

5. Test concentrations:
Pre-incubation assay: In the first and second test triplicate plates were prepared for each concentration (neg. control; 31.25, 62.5, 125, 250, 500, 1000, 2000, and 4000 µg/plate) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

1. Dates of experimental work: January, 1982

2. Dose range finding test:
In order to assess bacteriotoxic effects, a dose range finding test was conducted with Salmonella typhimurium TA 100 up to 6000 µg/plate. Up to 4000 µg/CIS-DVA per plate were shown to be non-toxic to the bacteria. Visible precipitation of the test substance was observed at 1000 µg per plate and above.

3. Plate-incorporation assay:
20 µL volumes of solution of the test substance were added to top agar mix to give final concentrations of 31.25, 62.5, 125, 250, 500, 1000, 2000, and 4000 µg/plate, as appropriate. Assays were carried out both in the presence and in the absence of rat liver S9 fraction. The cultures were incubated at 37°C for 48-72 h before the revertant colonies were counted. Means and standard deviations were calculated.

4. Statistics:
No special statistical tests were performed.

5. Evaluation criteria:
The test chemical is considered positive in this assay if the following criteria are met:

- A reproducible increase of 2.5-fold the control values or greater are considered to indicate a mutagenic response.

II. RESULTS AND DISCUSSION

A. TOXICITY
A bacteriotoxic effect was observed at concentrations higher than 4000 µg/plate in the dose range finding test. In the main experiments only concentrations were used up to the non-toxic dose of 4000 µg/plate.

B. MUTATION ASSAYS
In the 2 independent experiments with and without metabolic activation no biologically relevant increase in number of revertants was observed in any strain tested [see Table 5.8.1-2]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

Precipitation was observed at 1000 µg/plate and higher concentrations.

III. CONCLUSION

According to the results of the present study, the test substance CIS-DVA, Metabolite of BAS 310 I, alpha-Cypermethrin is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions applied.

Report: CA 5.8.1/12
[redacted] 1982a
Toxicology of pyrethroids 871: Acute oral, percutaneous toxicity, skin, eye irritancy, skin sensitizing potential of cis-2-(2,2-dichlorovinyl)-3,3-Dimethylcyclopropane carboxylic acid (cis-DVA) and -alpha-cyano-3-phenoxybenzyl-tosylate
AL-470-001
Guidelines: none
GLP: no
Remark: only data for M310I001 were extracted

Executive Summary

M310I001 (purity 99%) was tested for its acute oral and dermal toxicity, skin and eye irritation potential as well as skin sensitizing potential. The acute toxicity studies were conducted in rats, the irritation studies in rabbits, and the GPMT was performed with guinea pigs. The tests were conducted in a manner comparable to standard OECD guidelines and no major deviations were observed that would prevent an appropriate hazard assessment. In the acute oral toxicity test two out of 12 rats died at the limit dose of 5000 mg/kg bw, and thus a LD_{50} > 5000 mg/kg bw was derived. In the acute dermal toxicity test none of 12 rats died at the top dose of 1000 mg/kg bw (applied as a 50% solution in DMSO), and thus a LD_{50} > 1000 mg/kg bw was derived. M310I001 was not irritating to the skin or eyes, and no skin sensitizing potental was observed for M310I001. In conclusion, no hazard was identified in the acute systemic or local studies performed and no classification is warranted in either category.

Acute oral toxicity

Summary
A single dose of 5000 mg M310I001 (in DMSO) per kg bodyweight was applied to 6 male and 6 female Wistar rats via gavage. Animals were observed for clinical signs various times at the day of administration and at least once daily thereafter for a total of 14 days. Two female animals died at day 2 of the study period. Accordingly, the oral LD_{50} was found to be greater than 5000 mg/kg bw for males and females, respectively:

Rat, oral: LD_{50} > 5000 mg/kg bw

Clinical signs noted were comatose condition, muscle incoordination, lethargy, salivation, and piloerection. The mean body weights of the administration groups increased throughout the study period, with a slow retardation in the first week after administration. No necropsy was performed. Under the conditions of this study the median lethal dose of M310I001 after oral administration was found to be greater than 5000 mg/kg bw in males and females, respectively.

(DocID AL-470-001)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: CIS-DVA (Metabolite of BAS 310 I, Alpha-Cypermethrin)

Description:	Solid, beige, crystalline
Lot/Batch #:	BPDU 7, ST81/140
Purity:	99%
Stability	Infra-red spectroscopic fingerprint analysis revealed stability throughout the study period. Test substance formulation in DMSO were checked for stability by means of HPLC. Stability was confirmed for at least 70 h.

2. Vehicle: DMSO

3. Test animals:

Species:	Rats
Strain:	Wistar albino rats
Sex:	male/female
Age:	10-11 weeks (at study begin)
Weight at dosing (mean):	250-380 g (males), 150-250 g (females)
Source:	Shell Toxicology Laboratory (Tunstall) Breeding Unit
Acclimation period:	7 days
Diet:	Rat food (PRD, Labsure Animal Foods, Dorset), ad libitum
Water:	Tap water, ad libitum
Housing:	Four animals in clear polycarbonate cages with stainless-steel wire-mesh floors and tops
Environmental conditions:	
Temperature:	19-25 °C
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 6 am to 6 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 21-Oct-1981 - 05-Feb-1982 (Experimental period)

2. Animal assignment and treatment:
In a range-finding assay 50-5000 mg M310I001 per kg bodyweight were applied to one rat of each sex. In the main study 6 rats of each sex were dosed with 5000 mg/kg bw, which were fasted overnight (18 h). Solutions of the test substance were prepared daily. M310I001 was supplied as a 500 mg/mL solution in DMSO and was further diluted to the required volume with DMSO.
Clinical signs and symptoms were recorded several times at the day of administration and afterwards at least once daily for the individual animals up to 14 days post-administration. Individual body weights were determined shortly before administration, weekly thereafter and at the end of the study. No necropsy was performed.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality occurred in the range-finding assay when one animal of each sex was treated in the range from 50 to 5000 mg/kg bw. In the main study no mortality occurred within the males, whereby 2/6 females were found dead two days after administration of test substance.

B. CLINICAL OBSERVATIONS

In the males coma was observed within 2.5 h of dosing in 5/6 males and lasting 2 days. The male animal not suffering from coma showed muscular incoordination within 2.5 h of dosing also recovering at day 2. Further clinical signs included increased salivation, piloerection, and lethargy. All males were free from symptoms 4 days after administration.
Similar results were observed with the female animals. 4/6 females showed comatose condition, 1/6 females showed muscle incoordination and 1/6 females showed lethargy within 2.5 h after administration of test substance. Two of the comatose animals died at day 2. The remaining female animals recovered within 2 days.

C. BODY WEIGHT

The mean body weights of the administration groups increased at least in week 2 of the study period.

III. CONCLUSION

Under the conditions of this study, the oral LD_{50} in rats was determined to be greater than 5000 mg/kg bw for males and females.

Acute dermal toxicity

Summary
In an acute dermal toxicity study groups of 6 male and 6 female Wistar rats were exposed to a single dose of 1000 mg/kg bw of M310I001 (batch ST81/140, 50% solution in DMSO) to the clipped skin under occlusive conditions for 24 hours. The animals were observed for 14 days after administration. Based on the absence of mortality in this study the acute dermal LD_{50} was determined to be greater than 1000 mg/kg bw:

Rat dermal: LD_{50} > 1000 mg/kg bw

The mean body weights of the animals increased as throughout the study period. Clinical signs of toxicity included nasal bleeding and/or chromodacryrrhea (5/6 males; 6/6 females) and dermal irritation (1/6 males; 0/6 females). The majority of animals had recovered by day 2. No necropsy was performed. The available data on acute dermal toxicity of the test substance do not meet the criteria for classification according to Regulation EC Directive on dangerous preparations 1999/45/EC and Regulation (EC) No 1272/2008. Classification for acute dermal toxicity is therefore not warranted.

(DocID AL-470-001)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	CIS-DVA (Metabolite of BAS 310 I, Alpha-Cypermethrin)
Description:	Solid, beige, crystalline
Lot/Batch #:	BPDU 7, ST81/140
Purity:	99%
Stability	Infra-red spectroscopic fingerprint analysis revealed stability throughout the study period. Test substance formulation in DMSO were checked for stability by means of HPLC. Stability was confirmed for at least 70 h.
2. Vehicle:	The test substance was administered as a 50% solution in DMSO.

3. Test animals:

Species:	Rats
Strain:	Wistar albino rats
Sex:	male/female
Age:	10-11 weeks (at study begin)
Weight at dosing (mean):	250-380 g (males), 150-250 g (females)
Source:	Shell Toxicology Laboratory (Tunstall) Breeding Unit
Acclimation period:	7 days
Diet:	Rat food (PRD, Labsure Animal Foods, Dorset), ad libitum
Water:	Tap water, ad libitum
Housing:	3 animals in clear polycarbonate cages with stainless-steel wire-mesh floors and tops during the observation period. Single housing during 24-h treatment period.
Environmental conditions:	
Temperature:	19-25 °C
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 6 am to 6 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 21-Oct-1981 - 05-Feb-1982 (Experimental period)

2. Animal assignment and treatment:
In a range-finding study one animal of each sex was treated with 250-1000 mg test substance per kg bodyweight. In the main study five male and five female rats were treated with 1000 mg test substance per kg bodyweight for 24 h under occlusive conditions. The top dose of 1000 mg/kg bw was equivalent to the maximum dose volume that could be applied. The day before dosing the animals were weighed and approximately 60% of the dorsal hair was shorn with fine electric clippers. Directly before treatment the skin was visually inspected. The calculated dose was applied by syringe using a 50% test solution in DMSO. During treatment food was withheld but water was available ad libitum. At the end of the treatment the tape and aluminum foil were removed and the skin washed with warm dilute detergent solution and then dried. The animals were observed for signs of toxicity for 14 days after dosing. Body weights were recorded at day 0, day 7 and day 14.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality was observed in the range-finding and main study, respectively.

B. CLINICAL OBSERVATIONS

Clinical signs of toxicity included nasal bleeding and/or chromodacryrrhea (5/6 males; 6/6 females) and dermal irritation (1/6 males; 0/6 females). Nasal bleeding and chromodacryrrhea most often occurred within 2 hours of dosing. The majority of animals had recovered by day 2 and all animals had gained weight by the end of the 14 day observation period.

C. BODY WEIGHT

All animals had gained weight relative to their initial bodyweights by the end of the 14 day observation period.

III. CONCLUSION

Under the conditions of this study, the oral LD_{50} in rats was determined to be greater than 1000 mg/kg bw for males and females, respectively.

Acute dermal irritation

Summary

In an acute dermal irritation study, the skin irritation/corrosion potential of M310I001 (batch ST81/140, purity: 99%) was tested. The intact and abraded clipped skin of 3 male and 3 female New Zealand White rabbits was exposed to 0.5 g of the unchanged test substance for 24 hours covered with an occlusive dressing. Reactions on intact and abraded skin were quite similar, but only results from intact skin were taken into account for further assessment.

The cutaneous reactions were assessed 30 min, 48 and 72 hours after removal of the patch and then in weekly intervals until day 7 after treatment.

Slight erythema, observed in all animals immediately after removal of the patch were fully reversible in 5/6 and 6/6 animals after 48 and 72 h, respectively. Slight edema reactions at 24 h were fully reversible within 48 h in all animals. Mean scores over 24, 48 and 72 hours for each animal were within 0.16 and 0.5 for erythema and between 0.0 and 0.16 for edema. The overall 24 to 72 hour skin irritation scores were 0.39 for erythema and 0.05 for edema.

(DocID AL-470-001)

A. MATERIALS

1. Test Material: CIS-DVA (Metabolite of BAS 310 I, Alpha-Cypermethrin)

Description:	Solid, beige, crystalline
Lot/Batch #:	BPDU 7, ST81/140
Purity:	99%
Stability	Infra-red spectroscopic fingerprint analysis revealed stability throughout the study period.

2. Vehicle: The test substance was administered unchanged.

3. Test animals:

Species:	Rabbit
Strain:	New Zealand white
Sex:	3 males / 3 females
Age:	5-11 months
Weight at dosing:	males: 3.53 – 4.57 kg, females: 3.58 – 4.42 kg
Source:	Shell Toxicology Laboratory (Tunstall), Sittingbourne, UK
Acclimation period:	14 days
Diet:	SG1 with vitamin C supplement (Grain Harvesters Ltd., Kent, UK), ad libitum
Water:	Tap water (filtered), ad libitum
Housing:	Single housing in stainless steel wire mesh cages with grating, floor area: 2881 cm²
Environmental conditions:	
Temperature:	16 - 19 °C
Humidity:	No data
Air changes:	No data
Photo period:	No data

B. STUDY DESIGN AND METHODS

1. Dates of work: 21-Oct-1981 - 05-Feb-1982 (Experimental period)

2. In-vitro pre-test: No *in vitro* pre-test was conducted.

3. Animal assignment and treatment:
The potential of CIS-DVA to cause acute dermal irritation or corrosion was assessed by a single topical application of 0.5 g of the unchanged test substance for 24 hours to the intact untreated and abraded skin of three male and female New Zealand White rabbits using a patch of 2 cm x 2 cm. The test substance was covered with a lint patch and was occluded by an impervious polythene sheet held in place by means of an elastic adhesive bandage. After 24 hours the wrappings and patches were removed. Before treatment dorsal hair between the shoulders and hindquarters was closely shorn with fine electric clippers, and two test sites, approximately 10 cm apart and located lateral to the midline, were selected.
The cutaneous reactions were assessed 30 min after removal of the patch and at 48 and 72 hours and 7 days after application.

II. RESULTS AND DISCUSSION

Slight erythema (grade 0.5-1) was observed in all animals immediately after removal of the patch. At 48 h erythema (grade 0.5) were only visible in one animal and were fully reversible in all animals at the 72 h reading time point. Slight edema (grade 0.5) was present in 2/6 animals at 24 h. Edema reactions were fully reversible within 48 hours in all 6 animals. No further skin reactions were reported. Mean scores over 24, 48 and 72 hours were between 0.16 and 0.5 for erythema and between 0 and 0.16 for edema, respectively. The overall 24 to 72 hour skin irritation scores were 0.39 for erythema and 0.05 for edema. Individual and mean irritation scores after 24 hour dermal application of CIS-DVA are presented in Table 5.8.1-3.

III. CONCLUSION

Based on the findings of this study, M310I001 showed a minimal skin irritation potential to rabbits under the test conditions chosen.

Eye irritation

Summary
In an eye irritation study, the eye irritation/corrosion potential of M310I001 (batch ST81/140, purity: 99%) was determined by instillation of 100 mg of the unchanged test substance into the conjunctival sac of one eye of six New Zealand White rabbits. No washing was performed. The ocular reactions were assessed approximately 1, 24, 48 and 72 hours and 7 days after the administration of the test substance.
No effects on iris were observed in any animal at any time point. Very slight effects on cornea (grade 0.5) were observed at 24 h in 5/6 animals and were fully reversible within 7 days in 4/5 animals. In one animal a cornea score of 0.5 was still visible after 7 days. Moderate conjunctival redness (grade 2), observed in all animals 1 and 24 hours after application, decreased to slight at 48 and 72 h in most of the animals. Redness was fully reversible in 5/6 animals within 7 days. Only in 1/6 animals slight redness (grade 1) was still visible after 7 days. Slight conjunctival chemosis and discharge was noted at the 1 and 24 h reading. These effects were fully reversible after 72 h at the latest. The individual mean scores calculated over 24, 48 and 72 hours were within 0.0 and 0.5 for corneal opacity and 0 for iris lesions. Values for redness of the conjunctiva were within 1.33 (4/6 animals) and 2.0 (1/6 animals). Mean values for chemosis over 24, 48, and 72 h were within 0.16 and 0.83, respectively.

Photo period:	No data

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 21-Oct-1981 - 05-Feb-1982

2. In-vitro pre-test: No in vitro pre-test was conducted

3. Animal assignment and treatment:
The potential of CIS-DVA to cause acute eye irritation/corrosion was assessed by instillation of 100 mg of the undiluted test substance into the conjunctival sac of one eye. The lids were held together for a few seconds to prevent loss of material. No washing was performed. The ocular reactions were assessed approximately 1, 24, 48 and 72 hours and 7 days after dosing. In the event of any corneal damage visualization was aided by the instillation of one drop of fluorescein solution (2%). Body weights were determined shortly prior to application.

II. RESULTS AND DISCUSSION

The instillation of undiluted M310I001 into the conjunctival sac of one eye of each of six rabbits resulted in slight initial pain in the majority (4/6) of the animals and moderate initial pain in the other 2 animals. No effects on iris were observed in any animal at any time point. Very slight effects on cornea (grade 0.5) were observed at 24 h in 5/6 animals and were fully reversible within 7 days in 4/5 animals. In one animal a cornea score of 0.5 was still visible after 7 days. Conjunctival redness (grade 2) was observed in all animals after 1 and 24 h. These effects were slowly decreasing over time and were fully reversible in 5/6 animals after 7 days. Similarly, chemosis (grade 0.5 to 2) was observed after 1 and 24 h, was also slowly decreasing over time and was fully reversible within 72 h. Slight discharge (grade 0.5 to 1) was observed at 1 and 24 h only. No further effects on the eyes of rabbits were reported. The individual mean scores calculated over 24, 48 and 72 hours were within 0.0 and 0.5 for corneal opacity and 0 for iris lesions. Values for redness of the conjunctiva were within 1.33 (4/6 animals) and 2.0 (1/6 animals). Mean values for chemosis over 24, 48, and 72 h were within 0.16 and 0.83, respectively.
For details regarding the individual and mean scores as well as additional findings see Table 5.8.1-4.

III. CONCLUSION

Based on the findings of this study, M310I001 is mildly irritating to the eye of rabbits under the test conditions chosen. The available data on acute eye irritation of the test substance do not meet the criteria for classification according to Regulation EC Directive on dangerous preparations 1999/45/EC and Regulation (EC) No 1272/2008. Classification for acute eye irritation is therefore not warranted.

Skin sensitization

Summary
For the determination of potential sensitizing properties of M310I001 (batch: ST81/140, purity: 99%) a maximization test in guinea pigs ("P" strain) was conducted. Based on the results of a pre-test, the intradermal induction was performed with a 0.05% test item preparation in light liquid paraffin into the neck region of the animals. The epicutaneous induction (7 days after intradermal induction) and the challenge exposure (14 days after epicutaneous induction) were performed with a 50% test item preparation in petroleum jelly. The study was performed in 5 control and 10 test group animals per sex. Control group animals were treated with the same injection scheme as the test group animals but replacing the test item by the vehicle. Regarding epicutaneous induction, the control group animals were treated with the vehicle. 14 days after the last induction, the challenge was carried out. 0.3 mL of the 50% test substance preparation was applied for 24 hours to the intact skin of the flank under occlusive conditions. 24 and 48 hours after removal of the patch, skin readings were performed. No positive control was included in the study and no information regarding a periodic reliability check of the laboratory was given.
The intradermal induction with 0.05% test substance preparation caused positive reactions in all test group animals of the pre-test. No reactions were observed after epidermal induction with 50% test substance preparation in the animals during the pretest. No data were given for the animals of the main test. The challenge revealed no reactions in any animal of the control or test group, indicating that M310I001 has no skin sensitizing properties in the guinea pig maximization test under the conditions applied.

(DocID AL-470-001)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: CIS-DVA (Metabolite of BAS 310 I, Alpha-Cypermethrin)

Description:	Solid, beige, crystalline
Lot/Batch #:	BPDU 7, ST81/140
Purity:	99%
Stability:	Infra-red spectroscopic fingerprint analysis revealed stability throughout the study period. Solutions were stable for at least 7.5 h (expert statement)

2. Vehicle / Positive control:

Vehicles:
Light liquid paraffin, petroleum jelly
Positive control: not available

3. Test animals:

Species:	Guinea Pig
Strain:	"P"
Sex:	male/female
Age:	9 - 12 weeks
Weight at dosing:	437-792 g
Source:	Shell Toxicology Laboratory (Tunstall), Sittingbourne, UK
Acclimation period:	at least 14 days
Diet:	SG1 with vitamin C supplement, Grain Harvesters Ltd., Kent, UK, ad libitum
Water:	Tap water (filtered), ad libitum
Housing:	Groups of 2-3 animals were housed in stainless steel wire mesh cages with a floor area of approximately 1674 cm^2
Environmental conditions:	No details given

B. STUDY DESIGN AND METHODS

2. Dates of experimental work: 21-Oct-1981 - 05-Feb-1982

2. Animal assignment and treatment:
The skin sensitizing potential of M310I001 was assessed using the Maximization Test based on the method of Magnusson and Kligman. For this, male and female guinea pigs were randomly allocated to groups. Five animals per sex were used as control group animals and 10 animals per sex in the test group. Based on the results of a pre-test, animals were intradermally induced with 0.05% test substance preparations. Epidermal induction and challenge were conducted with 50% test substance preparations. The animals were closely shorn in the shoulder region using electric clippers followed by an electric razor; two rows of three injections were made, one on each side of the midline.

3. Clinical observation:
The animals were observed for a few days during the intradermal range finding test on general toxicity. No information is available from the main test.

4. Body weights:
Individual body weights were determined on day 0.

5. Pre-test:
100 µL of several dilutions of the test substance (0.05, 0.1, 0.5, and 1.0% in light liquid paraffin) were injected intradermally to 2 male and 2 female animals. The animals were examined over the next few days to determine the maximum concentration that could be used without causing untoward toxicity. Further groups of 2 male and 2 female animals were used to determine the irritation potential of the test substance applied at 25 and 50% in light paraffin and 60% in petroleum jelly. Therefore 0.3 mL of the test substance dilution was applied to the shaved flank of the animals and was covered with a "Poroplast" elastic adhesive bandage for 24 h. After exposure the skin reactions were assessed.

6. Main study – intradermal induction:
Based on the results of the pretest, test group animals received intradermal injections of 0.05% test substance preparations. A 0.05% test substance preparation (TS in light liquid paraffin) was intradermally injected to ten animals per sex. 6 intradermal injections were applied at the neck region of each animal: front row: 2 injections each of 0.1 mL Freund´s complete adjuvant without test item; middle row: 2 injections each of 0.1 mL of a test item preparation in vehicle at the selected concentration; back row: 2 injections each of 0.1 mL Freund's complete adjuvant / vehicle (1:1) with test item at the selected concentration. Skin reactions were assessed 24 hours after the beginning of the application. Control group animals received the same injections but with the test substance preparation being replaced by the vehicle.

7. Main study – epicutaneous induction:
One week after intradermal induction, 0.3 mL of the 50% test
light liquid paraffin caused a positive response in each 2 male and female animals. After topical item preparation (in petroleum jelly) was applied to each test group animal under the same conditions as described in the epidermal pretest but for 48 h. The control animals were treated similarly with vehicle only.

8. Main study - challenge:
The challenge was carried out 14 days after the epicutaneous induction. 0.1 mL of the 50% test item preparation was applied to the test and control group animal. The animals were exposed under occlusive conditions as described above for 24 hours and skin readings were performed 24 and 48 h after removal of the patch.

9. Evaluation of results
The number of animals with skin findings at 24 and/or 48 hours after the removal of the patch was taken into account for the determination of the sensitization rate. The evaluation "sensitizing" results if at least 30% of the test animals exhibit skin reactions.

10. Positive controls
No information on positive controls was given.

II. RESULTS AND DISCUSSION

A. PRE-TEST

Injections of 0.05, 0.1, 0.5, and 1.0% test substance preparations in induction no response was observed after treatment with 25 and 50% test substance preparation in light liquid petroleum or with a 60% preparation in petroleum jelly, respectively.

B. OBSERVATIONS

No abnormalities were observed during general observation.

C. BODY WEIGHTS

Body weights at start of treatment were within 437-792 g in the animals of the test group and within 503-693 g in the animals of the control group. No final body weights were given.

D. SKIN REACTIONS AFTER INTRADERMAL INDUCTION

According to the results from the pretest, intradermal induction with 0.05% test substance preparation in light liquid paraffin leads to a positive response. No details from the main study regarding intradermal induction were available.

E. SKIN REACTIONS AFTER EPICUTANEOUS INDUCTION

According to the results from the pretest, topical application of 50% test substance preparation in petroleum jelly leads to no dermal response. No details from the main study regarding topical induction were available.

F. SKIN REACTIONS AFTER CHALLENGE

The challenge with a 50% test substance preparation in petroleum jelly did not cause any skin reactions in animals of the control group and test group 24 and 48 hours after removal of the patch (see Table 5.8.1-5). Since no borderline results were observed, a 2nd challenge was not performed.

Table 5.8.1-5: cis-DVA - Skin reactions after challenge

	Challenge			
Skin findings	Control group		Test group	
	24 h	48 h	24 h	48 h
Grade 0	10/10#	10/10	19/20*	19/20*

x/y = number of findings / number of animals tested;
* = one animal was killed for humane reasons prior to topical induction stage

G. POSITIVE CONTROL

No information regarding positive control data was given.

III. CONCLUSION

Based on the results of this study it is concluded that M310I001 does not have sensitizing properties in the guinea pig maximization test under the test conditions chosen. 0% of the animals were considered positive after challenge application.

Endocrine modulation

Information with regard to the endocrine potential of M310I001 was found in the open literature. A summary table of the available literature is provided in Table 5.8.1-6 below. The literature is however described in more detail in the chapter CA 5.8.3.

In vitro studies:

M310I001 showed no estrogenic activity in yeast or mammalian ER-dependent transactivation assays, and no effect on androgen or thyroid receptor, neither as agonist nor as antagonist.

However M310I001 displayed anti-estrogenic effects when tested in competition with 17β-estradiol (1E-9M). While the anti-estrogenic effect starts in yeast cells in the µ-molar range, an antagonistic activity in mammalian cells is seen at concentrations of 7.23 nM. A significant reduction about 50% of the estradiol activation is seen in the low µM range.
M310I001 is one of the main metabolites of alpha-cypermethrin and when taking its phase II conjugation products into consideration as being formed out of M310I001 as well, this metabolite should have been in the system at a rate above 10% of the administered dose of alpha-cypermethrin. Therefore its toxicological properties are considered covered in the rat studies with alpha-cypermethrin. A relevant anti-estrogenic activity of this main metabolite would therefore be expected to be noticed in sensitive reproductive and developmental processes in studies with alpha-cypermethrin, or with any representative within the group of cypermethrins. Mainly one would expect effects like a delay of sexual maturation and vaginal opening. However, none of the regulatory studies indicate anti-estrogenic activity, and also literature data on cypermethrin were, if at al, discussing rather estrogenic activity of pyrethroids.

Considering all available data on endocrine potential M310I001 is considered to display some anti-estrogenic activity in vitro, however this is not mirrored in the regulatory in vivo studies in rats. Therefore this property is not considered relevant for further assessment.

Table 5.8.1-6: Endocrine activity studies with M310I001

Endpoint	Test system with endpoint	Endocrine activity	Positive control	Reference Doc ID
In vitro assays				
ER-activation	hER transactivation in Yeast (lacZ)	ER-agonist: Not active ER-antagonist: Active LOIC: 6±4E-05 M IC_{50}: 6.5±3.5E-04 M	Agonist: E2: EC50: 2.1±0.4E-10 M Antagonist:4HO-TAM: IC_{50}: 2.8±0.7E-6 M	Tyler et al., 2000 2000/1024078

PE: Proliferative effect; E2: 17 beta-Estradiol; EE: ethinyl estradiol; 4HO-TAM: 4-Hydroxy-tamoxifen; RPE: relative proliferative effect calculated as the ratio (PE-1) of the test chemical over (PE-1) of E2 (x 100); RIE: The relative inductive efficiency (RIE) is the ratio between the maximal up-regulation of pS2 expression level by the test compound to that of E2 (x100) or the relative inhibitory effciency of down-regulation of ERalpha expression level by the test compound compared to that of E2 (x 100); EC50/IC50: Effect concentration /Inhibitor concentration at which 50% increase /decrease is found compared to control; LOIC: Lowest observed inhibitory concentration

Toxicological evaluation of M310I001

The QSAR evaluation of M310I001 is of low reliability and by weight of evidence there was no conclusive alert for genotoxicity.

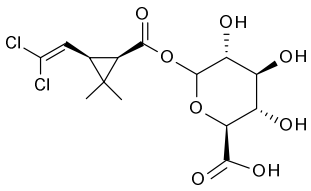
M310I001 is considered to be not genotoxic based on the in vitro studies conducted. Referring to the negative Ames test (see CA 5.8.1/1) the negative prediction for genotoxicity does reflect the experimental evidence. The acute toxicity studies conducted did not provide any evidence for significant acute systemic toxicity and/or significant effects on local tolerance.

M310I001 is considered to display some anti-estrogenic activity in vitro; however this is not mirrored in the regulatory in vivo studies in rats. Therefore this property is not considered relevant for further assessment.

With regard to chronic consumer exposure the TTC concept for a non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day. Moreover, the o-glycoside of M310I001 i.e. M310I004 is the major rat metabolite, and M310I001 the presumed precursor is expected to be immediately glucorinized when formed or uptaken in mammals and as such excreted. In conclusion the potential toxic properties of M310I001 are considered to be coverd by the testing of the parent molecule.

M310I001 is considered to be not genotoxic based on the available information. The in vitro evidence for anti-estrogenic activity is not considerd relevant due to the lacking evidence in apical in vivo studies. M310I001 is considered to be covered by the toxicological database for the parent. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. Therefore, M310I001 is considered to be **not toxicologically relevant**.

M310I004



M310I004 is a major metabolite found in rats and livestock animals (goat).

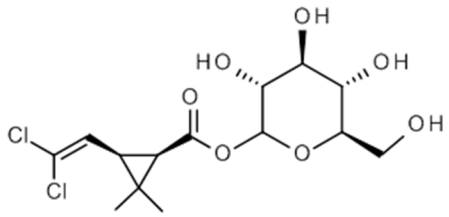
a. Toxicological evaluation of M310I004

Hydrolytic cleavage of the ester bound and elimination of the cis and trans cyclopropanecarboxylic acid moieties in the free and conjugated form is a major route of metabolism of cypermethrin in rats and in man [see section CA 5.1.1 of this dossier]. The cis and trans cyclopropanecarboxylic acid moiety were almost exclusively conjugated and rapidly eliminated as the ester glucuronide M310I004 (30% of the dose in male, 47% of the dose in females; trans representing 51.4% and cis 32.8% of the administered dose) with some free acid (twice as much trans as cis) being found in the urine (4%) together with traces of the trans-hydroxymethyl cyclopropyl acids (2%). Thus metabolite M310I004 as a major mammalian metabolite is covered by the toxicological testing of alpha-cypermethrin in mammals. M310I004 when uptaken into the gastrointestinal tract via the diet it is expected to be cleaved to the aglycone i.e. M310I001.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100% utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I004 is considered to be not genotoxic based on the available information on M310I001. M310I004 is considered to be covered by the toxicological database for the parent. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. Therefore, M310I004 is considered to be **not toxicologically relevant**.

M310I008



M310I008 is a plant metabolite (lettuce).

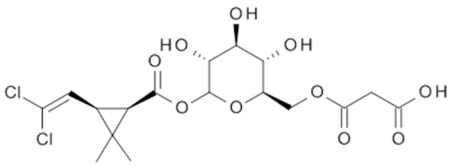
a. Toxicological evaluation of M310I008

Hydrolytic cleavage of the ester bound and elimination of the cis and trans cyclopropanecarboxylic acid moieties in the free and conjugated form is also a major route of metabolism of cypermethrin in the plant [see section CA 6.2 of this dossier]. In lettuce the presumed cis and trans cyclopropanecarboxylic acid moiety was glucose conjugated forming M310I008. When M310I008 is uptaken into the mamalian gastrointestinal tract via the diet it is expected to be cleaved to the aglycone i.e. M310I001 and thus to be covered by the toxicological evaluation of M310I001.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I008 is considered to be not genotoxic based on the available information on M310I001. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. Consequently M310I008 is considered to be **not toxicologically relevant.**

M310I009



M310I009 is a major metabolite found in rats and livestock animals (goat).

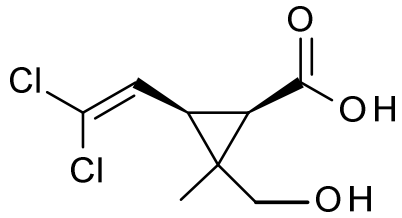
a. Toxicological evaluation of M310I009

Hydrolytic cleavage of the ester bound and elimination of the cis and trans cyclopropanecarboxylic acid moieties in the free and conjugated form is also a major route of metabolism of cypermethrin in the plant [see section CA 6.2 of this dossier]. In lettuce the presumed cis and trans cyclopropanecarboxylic acid moiety is glucose conjugated forming M310I008. This glycosylated compound is by malonylation on the glucose moiety metabolized into M310I009. When M310I009 is uptaken into the mamalian gastrointestinal tract via the diet it is expected to be cleaved to the aglycone i.e. M310I001 and thus to be covered by the toxicological evaluation of M310I001.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I009 is considered to be not genotoxic based on the available information on M310I001. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. Consequently M310I009 is considered to be **not toxicologically relevant**.

M310I003 (other denominators: HO-DCVA)



M310I003 is a mammalian metabolite found rat and livestock animals (goat, hen).

a. QSAR Predicitions on M310I003

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 6 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]9315]]
There were **no** Ames mutagenicity alerts for M310I003 or in-silico generated metabolites. Structural alerts were reported for the parent substance, namely "Haloalkenes with Electron-Withdrawing Groups". The same structural alerts were observed with several metabolites. For metabolite 6.1 the structural alert "Four-and Five-Membered Lactones" was reported.
The same holds true for in-vitro chromosome aberration. In all cases the structures were out of domain.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 6 of report [see KCA 5.8.1/5 2014/1289317]]
M310I003 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. One of the six most similar molecules had positive experimental data. The other five molecules were predicted 'non-mutagen', which was experimentally confirmed. The concordance of the total underlying database was moderate (0.675) and thus is not very robust. Both the positive (similarity 0.755) and the negative molecules (similarity 0.742 to 0.802) have a reasonably similar structure to M310I003. Therefore, the chemical space does adequately cover the structure of M310I003.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 6 of report [see KCA 5.8.1/5 2014/1289317]]
M310I003 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The same metabolites as reported in the CAESAR model were also used in the SarPy model. Of the five molecules that showed negative experimental data two were predicted positive.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 6 of report [see KCA 5.8.1/5 2014/1289317]]
M310I003 is in the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. All of the six most similar molecules were predicted 'non-mutagen', which was experimentally confirmed. The concordance of the total underlying database was high (1.0) and thus is very robust. All six molecules (similarity 0.703 to 0.728) have a reasonably similar structure to M310I003. Therefore, the chemical space does adequately cover the structure of M310I003.

Conclusion on QSAR evaluations
No conclusive structural alert was identified for M310I003.

Toxicological evaluation of M310I003

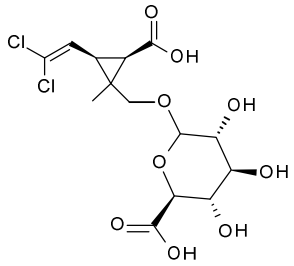
The QSAR evaluation of M310I003 is of moderate reliability and by weight of evidence there was no conclusive alert for genotoxicity.

Referring to the negative Ames test (see CA 5.8.1/1) of the structural similar substance M310I001 and the negative prediction for genotoxicity in various QSAR models, M310I003 is not considered to be genotoxic.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100% utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I003 is considered to be not genotoxic based on the available information on M310I001. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the relevant TTC-threshold.
In conclusion, M310I003 is considered to be **not toxicologically relevant**.

M310I002



M310I002 is a rat metabolite.

a. Toxicological evaluation of M310I002

Being a rat metabolite the toxicity of M310I002 is intrinsically covered by the toxicological testing of alpha-cypermethrin.

In conclusion M310I002 is considered to be **not toxicologically relevant**.

Toxicological evaluation of the Group C metabolites (DCVA, hydroxylated DCVA and its conjugates)

M310I004, M310I008 and M310I009 are o-bound glycosides of M310I001. These glycosides when uptaken into the human gastrointestinal tract via the diet are expected to be cleaved to the corresponding agylcone M310I001. The hydroxylated derivative of M310I001 i.e. M310I003 is due to its close structural relation to M310I001 not considered to be more toxic than M310I001. By weight of evidence M310I003 is not considered to be genotoxic. Thus the M310I001 derivatives, the glucones and M310I003 are considered to be covered by the toxicological evaluation of M310I001. M310I001 is not considered to be of toxicological relevance. Moreover M310I004 the glucuronid-ester of M310I001 is a major mammalian metabolite which is e.g. built in the rat at more than 30% of the applied dose. M310I003 and its glucuronid-ester M310I002 were also determined in the rat (1-2% of the applied dose). As the glucuronide ester M310I002 is formed from M310I003 whose precursor is the M310I001 itself the determination of the glucuronid ester in the rat further supports the coverage of the hydroxylated derivative M310I003 by the grouping approach.
Overall the group members are intrinsically covered by the mammalian metabolism and toxicological testing of the parent molecule alpha-cypermethrin. The central structure M310I001 and its derivatives did not provide and evidence for neurotoxicity and genotoxicity.

In conclusion the metabolites of the group C are by weight of evidence not considered to be genotoxic or neurotoxic. They are below the relevant thresholds of toxicological concern for acute and chronic dietary exposure and thus considered to be not toxicologically relevant.

Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates

I. Definition of group D: Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates

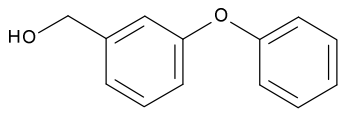
For the group of Group D) Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates, the following molecules were taken into consideration:

M310I024 (PBAlc)
M310I006 (o-glucoronide of PBAlc)
M310I018 (PBAld)
M310I011 (PBAcid)
M310I010 (glycine-conjugate of PBAcid)
M310I026 (glutamate-conjugate of PBAcid)
M310I013 and M310I025 (hydroxylated PBAcid)
M310I012 (glycine-conjugate of hydroxylated PBAcid)
M310I014 (sulfate-conjugate of hydroxylated PBAcid)

The redox-chain of phenoxy benzoic acid (PBAcid; M310I011), i.e. the aldehyde (M310I018) and the alcohol (M310I024) were grouped together. An o-glucoronide of M310I024 was included in this group. Furthermore the hydroxylated derivative of the phenoxy benzoic acid (M310I013/M310I025) was included here. For both acid metabolites M310I011 and M310I013/M310I025 glycine conjugates were determined in rat, livestock animals and/or plants i.e. M310I010 and M310I012. Furthermore a glutamate-conjugate of M310I011 was determined as a wheat metabolite (M310I026) and a sulfate conjugate of M310I013/M310I025 was determined as a rat metabolite (M310I014).

II. Evaluation of group D members: Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates

M310I024 (other denominators: CAS-No. 13826-35-2, Reg. No. 207323, PBAlc, 3-Phenoxybenzyl alcohol, WL 40673, CL 206128)



M310I024 is a plant metabolite found in wheat

a. QSAR Predicitions on M310I024

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 10 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]
There were **no** Ames mutagenicity alerts for M310I024 or in-silico generated metabolites and no structural alerts were reported. In all cases the structures were out of domain.
For in-vitro chromosome aberration the prediction for M310I024 was **negative** (out of domain). None of the 6 in-silico metabolites was predicted positive (out of domain) and no structural alerts were reported.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 10 of report [see KCA 5.8.1/5 2014/1289317]]
M310I024 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Three of the six most similar molecules had positive experimental data. The other three had the prediction non-mutagen, which was experimentally confirmed. The concordance of the total underlying database was moderate (0.67) and thus is not very robust. Both the positive (similarity 0.854 to 0.882) and the negative molecules (similarity 0.85 to 0.863) has a reasonably similar structure to M310I024. Therefore, the chemical space does adequately cover the structure of M310I024.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 10 of report [see KCA 5.8.1/5 2014/1289317]]
M310I024 is out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Three of the six most similar molecules had positive experimental data. The other three had the prediction non-mutagen, which was experimentally confirmed. The concordance of the total underlying database was low (0.33) and thus is not very robust. Both the positive (similarity 0.854 to 0.882) and the negative molecules (similarity 0.85 to 0.863) have a reasonably similar structure to M310I024. Therefore, the chemical space does adequately cover the structure of M310I024.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 10 of report [see KCA 5.8.1/5 2014/1289317]]
M310I024 could be out of the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. One of the six most similar molecules had positive experimental data. The concordance of the total underlying database was moderate (0.511) and thus is not very robust. All six molecules (similarity 0.827 to 0.87) have a reasonably similar structure to M310I024. Therefore, the chemical space does adequately cover the structure of M310I024.

Conclusion on QSAR evaluations
No conclusive structural alert was identified for M310I024.

Toxicological data of M310I024

For M310I024 results of toxicological studies are reported in the the DAR for lambda-cyhalothrin [see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013].

ADME

Supplemental information from open literature about toxicokinetics of pyrethroid metabolits in males and female rats was evaluated in the DAR or lambda-cyhalothrin [see Ueyama et al., 2010; discussed in Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 125-129] indicating that females eliminate M310I024 more rapid than male rats.

Acute toxicity

In non-accepted non-guideline studies with limited number of animals indication is given that the acute oral toxicity is greater than 500 mg/kg bw/day and the acute dermal toxicity > 4 ml/kg, that the compound is not irritant to the skin but irritating to the eye [see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 137-138, 140-141, 145-146, 150-151]. These studies were not considered acceptable and indicate that M301I024 is less toxic than alpha-cypermethrin.

Genotoxicity

Acceptable studies for genotoxicity in vitro - an Ames test, a Mouse Lymphoma Assay, and an in vitro chromosome aberration assay - were reported in the DAR for lambda-cyhalothrin [see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 188-187]. **No indications of mutagenic or clastogenic properties** were observed in these tests.

Endocrine modulation

Information with regard to the endocrine potential of M310I024 was found in the open literature. A summary table of the available literature is provided in Table 5.8.1-7 below. The Literature is however described in more detail in the chapter CA 5.8.3.

Endocrine modulation In vitro studies:
M310I024 has been reported to show distinct estrogenic effects on mRNA expression level for estrogen receptor and pS2 at approx. 1000-fold higher concentrations than beta-E2 (Jin et al., 2010; [see CA 5.8.3/17 2010/1232199]). Additionally it showed week estrogenic activity in two ER-dependent transactivation assays in the yeast (Tyler et al., 2000; [see CA 5.8.3/2 2000/1024078] and McCarthy et al., 2006; [see CA 5.8.3/16 2006/1051135]) but not in MCF-7 cells up to 10 µM (Laffin et al., 2010; [see CA 5.8.3/16 2010/1232196] and Tange et al., 2014; [see CA 5.8.3/2 2000/1024078]). The potency of M310I024 in yeast was about 100.000-fold lower than that of the positive control 17β-E2. No ER-antagonistic properties were found in yeast cells. Inconsistent data were reported from E-Screen assay in MCF-7 cells, one time inducing proliferation at 0.1 µM (Jin et al., 2010, [see CA 5.8.3/17 2010/1232199]), the other time showing no activity up to 10 µM (Laffin et al., 2010, [see CA 5.8.3/16 2010/1232196]). An induction of proliferation of MCF-7 cells is not directly attributable to an estrogenic effect; therefore the relevance of this information is questionable.

M310I024 was not active as androgen receptor agonist in yeast (Tyler et al., 2000; [see CA 5.8.3/2 2000/1024078]) and in mammalian cells (Tange et al., 2014; [see CA 5.8.3/9 2014/1242695]). An anti-androgenic potential was seen in yeast cells in the µ-molar range, however in mammalian cells the transactivation of human androgen receptor was not reduced to 50% even at 100 µM. Therefore this finding is rather considered unrelevant for further consideration.

Endocrine modulation In vivo studies:
Laffin et al., 2010 [see CA 5.8.3/16 2010/1232196] evaluated the estrogenic activity in vivo using the uterotrophic assay in Sprague-Dawley rats. Ovariectomized animals were orally gavaged at 1, 5, and 10 mg/kg bw of M310I024 dissolved in corn oil.once daily for 3 days. No effect on uterine wet weigth or body weight was found. In addition no effect on organ weights, onset of puberty and sexual maturation was found in a pubertal assay in Sprague-Dawley rats at 0, 1, 5 or 10 mg/kg bw/d administered from weaning (PND 22) until detection of the onset of puberty by vaginal opening.

Considering all available data on endocrine potential M310I024 can be considered as non active with regard to anti-estrogenic and androgenic potentail. Some anti-androgenic properties were found in yeast, but in mammalian cells only at higher concentrations so that this effect is not considered relevant for the in vivo situation. The estrogenic effect which was repeatedly found in vitro was not substantiated in a pubertal female assay or in an uterotrophic assay.

Table 5.8.1-7: Endocrine activity studies with M310I024

Endpoint	Test system with endpoint	Endocrine activity	Positive control	Reference Doc ID
In vitro assays				
ER-dependent regulation of mRNA expression	Estrogen Receptor (ERα) mRNA levels in MCF-7	Estrogenic active RIE: 88.7% at 1µM	E2: ↓(at 1nM) RIE set to 100%	Jin et al., 2010 2010/1232199
ER-dependent regulation of mRNA expression	pS2 mRNA levels in MCF-7	Estrogenic active RIE: 81.8% at 1µM	E2: 4-fold ↑ (1 nM) RIE set to 100%	
ER-activation	hER transactivation in Yeast (lacZ)	ER-agonist: Active EC_{50}: 2±0E-05 M ER-antagonist: Not active	Agonist: E2: EC_{50}: 2.1±0.4E-10 M Antagonist:4HO-TAM: IC_{50}: 2.8±0.7E-6 M	Tyler et al., 2000 2000/1024078

PE: Proliferative effect; E2: 17 beta-Estradiol; EE: ethinyl estradiol; 4HO-TAM: 4-Hydroxy-tamoxifen; RPE: relative proliferative effect calculated as the ratio (PE-1) of the test chemical over (PE-1) of E2 (x 100); RIE: The relative inductive efficiency (RIE) is the ratio between the maximal up-regulation of pS2 expression level by the test compound to that of E2 (x100) or the relative inhibitory effciency of down-regulation of ERalpha expression level by the test compound compared to that of E2 (x 100); EC50/IC50: Effect concentration /Inhibitor concentration at which 50% increase /decrease is found compared to control; LOIC: Lowest observed inhibitory concentration

Toxicological evaluation of M310I024

There is no evidence for M310I024 for substantial acute toxicity.

The QSAR evaluation of M310I024 is of moderate reliability and by weight of evidence there was no conclusive alert for genotoxicity.

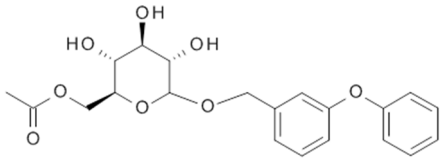
For M310I024 results from an Ames test, Mouse Lymphoma Assay, and an in vitro chromosome aberration assay were reported in the DAR for lambda-cyhalothrin [see Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 188-187]. No indications of mutagenic or clastogenic properties were observed in these tests. Therefore, based on the negative in vitro data regarding mutagenicity and clastogenicity in combination with the negative prediction for M310I024 in the various QSAR models, M310I024 is considered to be not genotoxic.

Furthermore M310I024 is considered to have no relevant endocrine activity.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I024 is not considered to be genotoxic and not considered to bear relevant endocrine activity. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. In conclusion, M310I024 is considered to be **not toxicologically relevant**.

M310I006



M310I006 is a plant metabolite (lettuce). Structurally is an o-glucuronide of M310I018.

a. Toxicological evaluation of M310I006

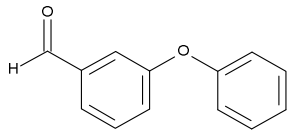
When M310I006 is uptaken into the mammalian gastrointestinal tract via the diet the o-glucuronide is expected to be cleaved to the aglycone i.e. M310I024 and thus to be covered by the toxicological evaluation of M310I024.

Based on the reported negative in vitro data regarding mutagenicity and clastogenicity for the aglycone M310I024 in combination with the negative prediction for M310I024 in the various QSAR models, M310I006 is considered to be not genotoxic.

Furthermore M310I006 based on the data available for the aglycone is considered to have no relevant endocrine activity.
With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I006 is considered to be not genotoxic based on the available information on M310I024. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the TTC-threshold. Consequently M310I006 is considered to be **not toxicologically relevant**.

M310I018 (other denominators: CAS-No. 39515-51-0, Reg. No. 4080665, PBAld, EC No. 254-487-1, WL 42049, CL 206969, 3-phenoxybenzaldehyde)



M310I018 is a metabolite found in plants (wheat) and is build by photolysis/degradation in water. M310I018 is registered at ECHA as an intermediate.

a. QSAR Predicitions on M310I018

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 13 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]
There were **no** Ames mutagenicity alerts for M310I018 or in-silico generated metabolites and no structural alerts were received. In all cases the structures were out of domain. The same holds true for the in vitro chromosome aberration.

VEGA: Mutagenicity model (CAESAR, version 2.1.12) [see molecule 6 of report [see KCA 5.8.1/6 2014/1319956]]
3-Phenoxybenzaldehyde could be out of the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts however the result show some critical aspects. The prediction is based on 6 molecules, of which three were predicted and actual 'mutagen'. The similarity to 3-Phenoxybenzaldehyde of the molecules in the data set is quite good as indicated by similarity factors of 0.848 to 0.871. The concordance of the total underlying database was bad (0.333) and thus is not very robust.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 6 of report [see KCA 5.8.1/6 2014/1319956]]
3-Phenoxybenzaldehyde could be out of the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The prediction is based on 6 molecules, of which three showed positive experimental values. The similarity of 3-Phenoxybenzaldehyde to the molecules in the data set is quite good as indicated by similarity factors of 0.848 to 0.871. The concordance of the total underlying database was bad (0.333) and thus is not very robust.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 6 of report [see KCA 5.8.1/6 2014/1319956]]
3-Phenoxybenzaldehyde is out of the model applicability domain. The prediction is **'mutagen'** with the specific structural alerts SA11 (Simple aldehyde) but with a low reliability as the most related structure of the model dataset having the same fragment was actual non-mutagen. The overall prediction is based on 6 molecules, of which two were predicted and actual 'mutagen' while the other four were non-mutagen. The similarity to 3-Phenoxybenzaldehyde of the molecules in the data set is quite good as indicated by similarity factors of 0.823 to 0.882. The concordance of the total underlying database was moderate (0.483) and thus is not very robust.

Conclusion on QSAR evaluations
A structural alert for mutagenicity was identified with the Toxtree module while there was no alert in the other models applied. However, the genotoxicity studies discussed below on M310I018 do not provide any evidence for genotoxity.

Toxicity studies on M310I018

The datapackage published on the ECHA homepage for registration as an intermediate (Joint Sumbission) comprises of acute and local tolerance studies only [http://apps.echa.europa.eu/registered/data/dossiers/DISS-9eb9f3aa-13ef-2d26-e044-00144f67d031/AGGR-afb51bdd-4549-4bc9-9043-798d39a91cab_DISS-9eb9f3aa-13ef-2d26-e044-00144f67d031.html#L-089e8c2d-346d-4d75-b2cf-5d474bd41acf]. Based on these studies a classification Acute Tox 4 H302: Harmful if swallowed and Acute Tox 2 H330: Fatal if inhaled is proposed. The acute dermal toxicity study and the skin and eye irritation studies did not guide to a hazard classification.

An extensive datapackage on M310I018 is available to the applicant from the TSCATS database. A summary table of the available studies is provided in Table 5.8.1-8 below. The acute studies and local tolerance studies although not discussed in detail support the classification proposal on the ECHA homepage. However there is additional evidence that M310I018 might be skin sensitizer. Studies of the TSCATS database considered relevant for dietary metabolite assessment are described in more detail in the following section.

Table 5.8.1-8: Summary of TSCATS toxicological studies on M310I018

Study Title	Substance	Species/Sex	Dose range (vehicle)	Result	Guideline/GLP	Reference (BASF DocID)
Ninety Day Subchronic Oral Toxicity Study of m-PBAD in albino rats	M310I018, Lot No.: 82-92, Purity: 97%	Sprague-Dawley rats (M/F)	50, 150, 300 mg/kg bw/day (corn oil)	NOEL: 50 mg/kg bw	Equivalent to OECD 408, not GLP, QAU	1980/1001707
Histopathology results from 90-day oral rat study with meta-phenoxybenzaldehyde (final report)	M310I018, Lot No.: 82-92, Purity: 97%	Sprague-Dawley rats (M/F)	50, 150, 300 mg/kg bw/day (corn oil)	NOEL: 50 mg/kg bw		1980/1001708
Disposition of 14C-labeled meta-phenoxybenzaldehyde following oral dosing in rats (final report)	^{14}C-labelled M310I018 radiochemical purity: 99.9%, specific activity 11.3 mCi/mmol	Sprague-Dawley rats (M/F)	150 mg/kg bw/day (corn oil)	Readily absorbed and distributed to various organs and tissues. Higher urinary excretion in males vs. higher fecal excretion in females.	-	KCA 5.8.1/13 1981/1001421

GLP: no

Executive Summary

S. typhimurium (strains TA98, TA 100, TA 1535, TA 1537 and TA 1538) were exposed to M310I018; Lot No. 1) using DMSO as a solvent in the presence and absence of metabolic activation in one plate incorporation test. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment. The test substance was used at concentrations of 3, 10, 30, 100, and 300 µg/plate in the presence and absence of S9-mix. Bacteriotoxic effects (pindot colonies) were observed in a range finding test at concentrations of 500 µg/plate or higher in TA 100 and TA 1535. In TA 100 a reduced number of revertant colonies was observed at the 160 µg/plate level. A biologically relevant increase in the number of revertant colonies was not noticed in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains in the absence or presence of metabolic activation. According to the results of the study the test substance the test substance was not mutagenic in the Salmonella typhimurium mutation assay under the experimental conditions of the study.

(Doc ID 1985/1002161)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material 3-PBAD III (Meta-phenoxybenzaldehyde (Metabolite of BAS 310 I, Alpha-Cypermethrin)

Description:	liquid / yellow
Lot/Batch #:	Lot 1
Purity:	N.A.
Stability of test compound:	The test substance was stable over the study period

2. Control Materials:

Vehicle control: The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	Sodium azide (NaN_3)	Water	10 µg/plate
TA 1535	Sodium azide (NaN_3)	Water	5 µg/plate
TA 1537	9-Aminoacridine	DMSO	150 µg/plate
TA 1538	2-Nitrofluorene	DMSO	5 µg/plate
TA 98	2-Nitrofluorene	DMSO	5 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-Aminoanthracene	DMSO	5 µg/plate
TA 1535	2-Aminoanthracene	DMSO	5 µg/plate
TA 1537	2-Aminoanthracene	DMSO	5 µg/plate
TA 1538	2-Aminoanthracene	DMSO	5 µg/plate
TA 98	2-Aminoanthracene	DMSO	5 µg/plate

3. Activation:

S9 was produced from the livers of Sprague-Dawley rats treated with Aroclor 1254. The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The rat liver S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Sodium phosphate buffer (pH 7.4)	100 mM
Glucose 6-phosphate	5 mM
NADP	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10 %

No information regarding the efficiency of the S9-batch, in general, was provided (i.e. incubation with B[a]P).

4. Test organisms:

S. typhimurium strains: TA98, TA100, TA1535, TA1537, TA1538

5. Test concentrations:

Preliminary experiment: Duplicate plates were prepared for each concentration (solvent control; 50, 166, 500, 1666, and 5000 µg/plate) in the absence of S9-mix in Salmonella strains TA 1535 and TA 100.

Plate incorporation assay: Triplicate plates in one experiment were prepared for each concentration (neg. control; 3, 10, 30, 100, and 300 µg/plate) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

1. Dates of study period: 15 January, 1985 – 4 March 1985

2. Preliminary toxicity test:

In order to assess bacteriotoxic effects, a dose range finding test was conducted with Salmonella typhimurium TA 100 and TA 1535 up to 5000 µg/plate test substance concentration. Top agar, used as an overlay, was reconstituted into a molten state and supplemented with 0.5 mM histidine – 0.5 mM biotin at a volume of 0.1 mL/mL of agar, and maintained at 45°C until used. Two mL of top agar solution, 0.1 mL of tester strain and 0.1 mL of the appropriate concentration of the test compound were added to a sterile tube, vortexed and poured onto minimal glucose plates.

3. Plate-incorporation assay:

100 µL volumes of solution of the test substance were added to top agar mix to give final concentrations of 3, 10, 30, 100, and 300 µg/plate. The procedure was identical to that described for the preliminary toxicity test. Assays were carried out both in the presence and in the absence of rat liver S9 fraction. The cultures were incubated at 37°C for 48 h before the revertant colonies were counted. Means and standard deviations were calculated.

4. Statistics:

No special statistical tests were performed.

5. Evaluation criteria:

The test chemical is considered positive in this assay if the following criteria are met:

- A reproducible and significant dose-related increase of revertant colonies
- An increase of revertant colonies equal to or greater than three times the solvent control value, if the solvent control values were within the 95% confidence limit of the historical control data.

A negative result is defined as the absence of a reproducible increase in the number of histidine-independent colonies.

II. RESULTS AND DISCUSSION

A. PRELIMINARY TOXICITY TEST

Cytotoxicity (pindot colonies) was observed at 500, 1666, and 5000 µg/plate for TA 100 and TA 1535 in the preliminary toxicity test. Strain TA 100 also exhibited a reduced number of revertant colonies at the 160 µg/plate level. Based on these findings the top dose selected for the main experiment was 300 µg/plate.

B. MAIN EXPERIMENT

In the main experiment with and without metabolic activation no biologically relevant increase in number of revertants was observed in any strain tested [see Table 5.8.1-9]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

III. CONCLUSION

According to the results of the present study, the test substance M310I018 is not mutagenic in the Salmonella typhimurium assay under the experimental conditions applied.

Report: CA 5.8.1/32
Schechtman L.H., 1991a
m-PBAD - Activity of T1409 in the in vivo cytogenetics assay in rodents (final report with cover letter)
1979/1001668
Guidelines: none
GLP: no

Executive Summary

M310I018 (purity: 97%) was tested in vivo for the ability to induce chromosome and numerical aberrations in bone marrow cells of male Sprague-Dawley rats. Five animals per dose group were treated with 0.22, 2.2, and 22 µL/kg bw once daily by gavage for 5 consecutive days, with an administration volume of 4 mL/kg bw (corn oil). Two hours after administration of the final treatment, the animals were injected intraperitoneally with 4 mg/kg bw colchicine. Four hours after treatment with colchicine, the animals were sacrificed by carbon dioxide asphyxiation and both femurs and tibias were removed. Bone marrow cells were isolated, fixed with Carnoy´s fixative, and stained with Giemsa. Vehicle (corn oil) and positive control (TEM, 0.5 mg/kg bw) were included to demonstrate the sensitivity of the test system.

One animal of dose group 3 demonstrated a gradual weight loss and died after administration of the fifth dosage. On necropsy, there were no gross lesions observed. Otherwise, there were no adverse effects from the treatment and other animals died as a result of the dosing regimen. There was no change in ploidy in the treatment groups relative to the negative control. The damage was so severe in the positive control that the chromosome number could not be counted. The mitotic index of all treatment groups was unchanged from that of the negative control. TEM was a moderate mitotic inhibitor. The percentage of cells with aberrations for all treatment groups was not significantly ($p>0.05$) increased relative to the negative control. The group receiving TEM demonstrated severe damage, with approximately 74% of all cells analyzed containinig one or more aberrations. The aberrations per cell for all treatment groups were not significantly increased ($p>0.05$) relative to the negative control using the t-test. The group receiving TEM demonstrated severe damage, with approximately 5.86 aberrations per cell.

Based on the results of this study, it can be stated that under the experimental conditions reported, M310I018 did not induce chromosome aberrations in bone marrow cells from Sprague-Dawley rats.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: T1409 (3-Phenoxybenzaldehyde)

Description:	Liquid, pale yellow
Density:	1.49
Lot/Batch #:	not reported
Purity:	97%
Stability of test compound:	not reported
Solvent used:	Corn oil

2. Control Materials:

Negative control:	A negative control was not employed in this study.
Solvent control:	Corn oil
Positive control:	Triethylenemelamine (TEM)

3. Test animals:

Species:	Rat
Strain:	Sprague-Dawley
Sex:	male
Age:	4-6 weeks
Weight at dosing:	125 - 200 g
Source:	Charles River Breeding Farms, Wilmington, USA
Acclimation period:	Not reported (10-14 days of quarantine)
Diet:	Purina Rat Chow, ad libitum
Water:	Tap water, ad libitum
Housing:	Group housing (5 animals/cage)
Environmental conditions:	
Temperature:	not reported
Humidity:	not reported
Air changes:	not reported
Photo period:	not reported

4. Test concentrations:

Main experiment:	0.44, 4.4, and 44 µL/kg bw (at a dosing volume of 4 mL/kg bw of T1409 in corn oil)

B. STUDY DESIGNS AND METHODS:

1. Dates of experimental work: 23-July-1979 to 06-Aug-1979

2. Main experiment:

Treatment

Five animals per group were dosed with 0.44, 4.4, and 44 µL/kg bw of the test substance once daily by oral gavage for 5 consecutive days. The calculated total dose was 2.2, 22, and 22 µL/kg bw. The solvent control animals received corn oil at 4 mL/kg bw by gavage for 5 consecutive days. Positive control animals received Triethylenemelamine (TEM) intraperitoneally as a single dose of 0.5 mg/kg bw one day prior to sacrifice. Two hours after administration of the final treatment, the animals were injected intraperitoneally with 4 mg/kg bw colchicine.

Preparation of the animals

Four hours after treatment with colchicine, the animals were sacrificed by carbon dioxide asphyxiation and both femurs and tibias were removed. The epiphysis was broken and the marrow aspirated into HBSS. The cells were centrifuged at 1000 rpm for 8-10 minutes, the supernatant decanted, and the cell pellet resuspended in 8 mL of 0.075 M KCl. The tubes were incubated in a 37°C water bath for 20-30 min, centrifuged at 1000 rpm for 8-10 min and the supernatant decanted. The cells were resuspended in 5 mL Carnoy´s fixative and incubated at 4°C for 2 h. Afterwards cells were centrifuged at 1000 rpm for 8-10 min, the supernatant discarded, and the cells resuspended in 5 mL Carnoy´s fixative. After an overnight (16-20 h) incubation at 4°C, the cells were centrifuged at 1000 rpm for 8-10 min and the supernatant decanted. The cell pellet was resuspended to opalescence in Carnoy´s fixative. Two to 5 slides were prepared from each animal. Slides were stained with Giemsa and permanently mounted.

Analysis of metaphase cells

A minimum of 50 metaphase spreads from each animal was examined and scored for chromatid and chromosomal gaps and breaks, structural arrangements, ploidy, fragmentation and pulverization. The mitotic index was recorded for each rat as the number of cells in mitosis/100 cells observed. Each cell was classified into a single category (chromatid or chromosome gaps, breaks, structural rearrangements, fragments and pulverizations) according to the most severe damage that occurred. The percentage of damaged cells in the total population of cells examined was calculated for each treatment group. Chromatid and chromosome gaps are not included in the total percentage of cells with one or more aberrations. The severity of damage within the cells is reported as the number of aberrations per cell per treatment dose.

3. Statistics:

Chi-square analysis using a 2x2 contingency table was used to ascertain significant relationships between the number of cells with aberrations in the treatment group relative to the negative control. The t-test was used to compare pairwise the number of aberrations per cell of the treatment group with that of the negative control. Each comparison was considered to be between two independent, random samples of unequal variance and a significant increase in the treatment mean relative to the negative control (one-sided) was being sought.

4. Acceptance and evaluation criteria:

Acceptance criteria

The study was considered valid as the following criteria are met:

- The mitotic index for all animals of the negative control group must be at least 8%.
- The number of cells demonstrating chromosome and chromatid breaks and gaps must be less than or equal to 2% of the total cells analysed for each negative control animal.
- The mitotic index for the positive control is expected to be between 1-4%. The average number of cells demonstrating chromosome or chromatid aberrations must be at least 55% of the total cells analyzed in the positive control group.

Evaluation criteria

The test chemical is classified mutagenic if it induces significant damage (number of aberrations per cell/percentage of damaged cells). No further details were reported.

II. RESULTS AND DISCUSSION

A. MAIN EXPERIMENT:

One animal of dose group 3 demonstrated a gradual weight loss and died after administration of the fifth dosage. On necropsy, there were no gross lesions observed. Otherwise, there were no adverse effects from the treatment and o other animals died as a result of the dosing regimen.
There was no change in ploidy in the treatment groups relative to the negative control. The damage was so severe in the positive control that the chromosome number could not be counted. The mitotic index of all treatment groups was unchanged from that of the negative control. TEM was a moderate mitotic inhibitor.
The percentage of cells with aberrations for all treatment groups was not significantly ($p>0.05$) increased relative to the negative control. The group receiving TEM demonstrated severe damage, with approximately 74% of all cells analyzed containinig one or more aberrations.
The aberrations per cell for all treatment groups were not significantly increased ($p>0.05$) relative to the negative control using the t-test. The group receiving TEM demonstrated severe damage, with approximately 5.86 aberrations per cell.

	55	6	0	0	0	0	40	0	15	0	0	24

Discussion
The negative (corn oil) controls were within the normal range of values for this species and strain as observed in this laboratory. The positive control (TEM) exhibited its usual severe genetic damage. The chromosome number varied due to severe damage, 74% of the cells were characterized by chromosomal aberrations, and an average of 5.86 aberrations per cell was recorded. In this study, the test compound M310I018 appeared to exhibit little or no clastogenic activity. No dose response was observed.

III. CONCLUSION

Under the conditions employed in the assay described in this report, the data suggest that the test compound exhibits little or no mutagenic activity in the in vivo cytogenetics assay.

Report: CA 5.8.1/33
Putman D.L., 1991a
m-PBAD - Activity of T1410 in the dominant lethal assay in rodents for mutagenicity (final report with cover letter)
1979/1001669
Guidelines: none
GLP: no

Executive Summary

A dominant lethal assay was performed with male and female SD rats. Three groups of male rats (10 per group) were given 5 intragastic treatments with the test substance at levels of 216 mg/kg bw (LD5), 21.6 mg/kg bw (LD0.5), and 2.16 mg/kg bw (LD0.05). Corn oil served as negative control and triethylene melamine was used as positive control. After the treatment period each male was mated with 2 females for 5 days, rested for 2 days, and was again mated with 2 females. This procedure was repeated until each male had been mated for 7 weeks with 2 new females. Fourteen days from the mid-week of mating, the females were sacrificed, and the females were examined for corpora lutea, fetal deaths and total implantations, respectively. The negative controls were within the acceptable range of values for the species and strain when compared to the laboratory historical control data. The positive control exhibited its usual severe genetic damage between weeks 2 and 7 as shown by greater preimplantation losses, increased number of dead implants per female, and an increase in females with one or more dead implants. Treatment with M310I018 exhibited minimal activity in the number of total implantations, preimplantation losses, and number of live implants per pregnant female. However, the effect on total or live implants per pregnant female occurred at a single dose level at week 7 only. The variation in corpora lutea at week 5 does not reflect any biological activity of the doses tested but rather is a variation in the female animals. The increase seen in pre-implantation losses at week 6 is probably a result of the unusually high corpora lutea counts for this time period rather than actual biological activity of the doses tested. No statistically significant dose response was observed. No effects were observed regarding fertility index, number of dead implants per pregnant female or per total implants, respectively. Under the conditions employed in the assay the data suggest that the M310I018 exhibits little or no mutagenic activity in the dominant lethal test.

Report: CA 5.8.1/34

m-PBAD - Ninety-day subchronic oral toxicity study of meta-phenoxybenzaldehyde in albino rats (final report with cover letter)
1980/1001707
Guidelines: none
GLP: no

Report: CA 5.8.1/35
[redacted] 1991a
m-PBAD - Histopathologic evaluation of tissuues and organs from albino rats in a 90-day subchronic oral dosing study with meta-phenoxybenzaldehyde (final report)
1980/1001708
Guidelines: none
GLP: no

Executive Summary

The oral administration of M310I018 to male and female Sprague-Dawley rats over a period of 90 days did not reveal test substance related adverse signs of systemic toxicity at dose levels of 50, 150, or 300 mg/kg bw/d. Increased liver and kidney weights were observed, but were considered to be related to increased metabolic activation rather than to substance specific effects.
The mean weekly body weights by sex for all groups were virtually identical throughout the study period. However, beginning at week 3 group 3 and 4 weekly food consumption means were significantly greater when compared to the control. Clinical pathology results indicated elevation of AST, ALT, and ALP in groups 3 and 4. Furthermore, there was a dose related increase in liver weight and liver/body weight and liver/brain weight ratios for group 4. Similarly, the kidneys were affected in groups 3 and 4. These findings indicate an increase in metabolic activity of these organs with increased production of serum enzymes. Histopathology did not reveal an increase in non-neoplastic lesions in albino rats under the conditions of the study.
The no observed effect level (NOEL) under the conditions of the present study was 50 mg/kg bw/day in male and female Sprague-Dawley rats.

(DocID 1980/1001707, 1980/1001708)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Meta-phenoxybenzaldehyde (Metabolite of BAS 310 I, Alpha-Cypermethrin)

Description:	liquid / yellow
Lot/Batch #:	82-92 and 189
Purity:	97%
Stability of test compound:	The test substance was stable over the study period

2. Vehicle and/or positive control: Mazola® corn oil

3. Test animals:

Species:	Rat
Strain:	Sprague-Dawley
Sex:	Male and female
Age:	no data
Weight at dosing:	160-260 g
Source:	Gibco Animal Resources, Madison, Wisconsin, USA
Acclimation period:	3 weeks
Diet:	Purina Certified Rodent Chow 5002®, ad libitum
Water:	Drinking water, ad libitum
Housing:	Single housing in stainless-steel wire mesh cages

Environmental conditions:

Temperature:	no data
Humidity:	no data
Air changes:	no data
Photo period:	no data

B. STUDY DESIGN

1. Dates of experimental work: 03-Jan-1980 - 04-Apr-1980

2. Animal assignment and treatment:
M-PBAD was administered to groups of 20 male and 20 female Sprague-Dawley rats at concentrations of 0, 50, 150, and 300 mg/kg bw/day via gavage for 90 days. The animals were randomized and assigned to the treatment groups. At the end of the administration period the animals were sacrificed after a fasting period of at least 16 hours. Ten rats per sex were used in a range-finding study to establish baseline clinical pathology values.

3. Test substance preparation and analysis:
Freshly mixed solutions were used for administration and were analyzed before administration to test animals. Assays of stock solutions were within 10% of the specified concentration. The dose volumes were 5, 5, 1.5, and 3 mL/kg for the rats of group 1 (control), 2 (50 mg/kg bw), 3 (150 mg/kg bw), and 4 (300 mg/kg bw), respectively.

4. Statistics:
Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following table:

Statistics applied

Parameter	Statistical test
Body weight, organ weights, feed consumption, hematology, clinical chemistry	Analysis of variance, ANOVA, and Tuke´s HSD procedure

C. METHODS

1. Observations:
The animals were examined for general appearance, elimination, behavior and mortality once daily.

2. Body weight:
The body weight of the animals was determined before the start of the administration period (in order to randomize the animals), at the start of the treatment (day 0) and at weekly intervals thereafter.

3. Food consumption:
Food consumption was determined weekly and calculated as mean food consumption for each group.

4. Hematology and clinical chemistry:
Predose blood samples were taken from the 10 male and female animals not assigned to treatment groups. At day 45 and 90 blood samples were collected from 10 males and 10 females randomly selected from each group. Blood was collected from the abdominal aorta at predose and at day 90. At day 45 blood was collected via puncture of the retro-orbital sinus.
The following hematological and clinical chemistry parameters were determined:

Hematology:					
	Red blood cells		White blood cells		Clotting Potential
✓	Erythrocyte count (RBC)	✓	Total leukocyte count (WBC)	✓	Platelet count
✓	Hemoglobin (Hb)	✓	Differential blood count		
✓	Hematocrit (Hct)				
Clinical chemistry:					
	Electrolytes		Metabolites and Proteins		Enzymes:
✓	Calcium	✓	Albumin	✓	Alanine aminotransferase (ALT)
✓	Potassium	✓	Bilirubin (total and direct)	✓	Aspartate aminotransferase (AST)
		✓	Cholesterol	✓	Alkaline phosphatase (ALP)
		✓	Globulin (by calculation)	✓	Lactic dehydrogenase
		✓	Glucose (fasted)		
		✓	Protein (total)		
		✓	Urea		

5. Urinalysis:

Predose urine samples were taken from the 10 male and female animals not assigned to treatment groups. At day 45 and 90 urine samples were collected from 10 males and 10 females randomly selected from each group.

Urinalysis					
	Quantitative parameters:		Semiquantitative parameters		
✓	Specific gravity	✓	Bilirubin	✓	Protein
		✓	Glucose	✓	pH-value
		✓	Ketones	✓	Urobilinogen
				✓	Sediment (microscopical exam.)

6. Sacrifice and pathology:
Clinical pathology investigations were performed 1-3 days before dosing (predose), day 45 of dosing, and day 90 of dosing. After 90 days of dosing all surviving rats were fasted for at least 8 h, anesthetized, killed by exsanguination, and necropsied. The gross necropsy included examination of the carcass, the external surface, all orifices, the cranial cavity, the thoracic, abdominal, and pelvic cavities with their associated organs and tissues, and the neck with its associated organs and tissues. Organ weights for the liver, kidneys, adrenals, gonads, heart, spleen, and brain were recorded for all study animals. Organ/body and organ/brain weight ratios were calculated. Tissues from rats in group 1 and 4 were taken for histopathologic examination and from group 2 and 3 rats for fixation. A histopathologic examination of 44 tissues per animal was conducted in the control and high dose group. Among them were tissues of the reproductive system as epididymides, seminal vesicles, prostate, testes, fallopian tubes, cervix, vagina, mammary gland, ovaries, and uterus. In addition, tissues of the nervous system were examined including pons, optic nerve, peripheral nerve, and spinal cord. Furthermore, liver, kidney, and heart were evaluated from all animals of 50 and 150 mg/kg bw dose groups. The organs were sampled, weighed, and examined histopathologically as indicated in the table below.

Pathology:
The following organs were collected (column C), weighed (W) and examined histopathologically (H, ✓: all groups, #: control and top dose).

§ from femur

The organs or tissues were fixed in 10% formalin solution (eyes and testes in Bonin´s solution). The hematoxylin-eosin (HE) stained slides were examined and assessed by light microscopy.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

22 animals (14 females, 8 males) exhibited small white corneal opacities in one or both of their eyes. These lesions were present at the initiation of the study, were virtually unchanged throughout the study, and were not treatment related. Other observations, such as ocular discharge, sneezing, unthrifty appearance, alopecia, broken skin, etc. appeared for a short duration in all groups early in the study, but tended to be more common in the high treatment groups.

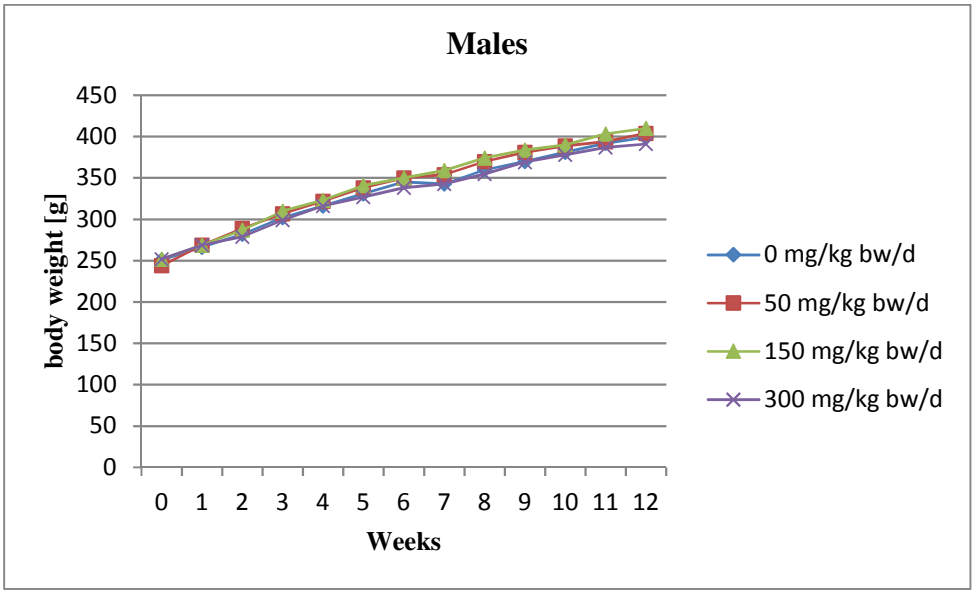
2. Mortality

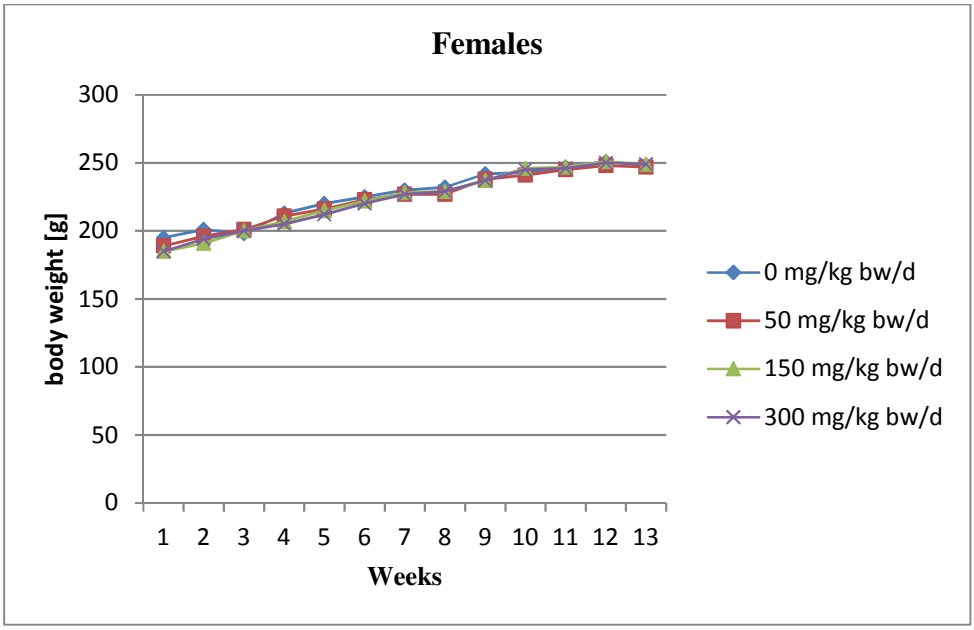
Nineteen animals died before study termination. These deaths were considered to be not related to substance administration, rather attributed to injuries from gavaging or accidental injuries.

B. BODY WEIGHT AND BODY WEIGHT GAIN

The mean body weight of the control group was not significantly different when compared to the treatment groups. In several instances, a statistically significant difference in means for weekly weight gain was seen between control and treatment groups [see Figure 5.8.1-4].

Figure 5.8.1-4: Body weight development of rats administered M310I018 for 90 days





C. FOOD CONSUMPTION

Both mean and individual feed consumption data for group 3 and 4 (150 and 300 mg/kg bw) of both sexes showed a trend of increasing food consumption over time. Statistically significant differences were seen in comparing group means for food consumption for group 3 and 4 with that of the control (see Table 5.8.1-13).

Table 5.8.1-13: Cumulative food consumption of rats administered M310I018 for 90 days

	Males				Females			
Dose level [mg/kg bw/day]	0	50	150	300	0	50	150	300

D. BLOOD ANALYSIS

1. Hematological findings

Group mean data for hematology parameters showed no apparent abnormalities or trends. Incidental variations are listed in Table 5.8.1-14.

Table 5.8.1-14: Selected hematology findings in rats administered M310I018 for 90 days (group means)

	Study day	RBC [10^6]	HGB [mmol/L]	HCT [g/dL]
	Males			
Control	Day 90	9.25 ± 0.17	17.42 ± 0.63	50.70 ± 1.89
50 mg/kg bw/day	Day 90	**8.90 ± 0.53***	16.79 ± 0.65	49.80 ± 2.15
150 mg/kg bw/day	Day 90	9.22 ± 0.24	16.97 ± 0.60	50.20 ± 2.15
300 mg/kg bw/day	Day 90	9.26 ± 0.15	17.08 ± 0.61	**49.33 ± 1.80***

150 mg/kg bw/day	Day 90	8.22 ± 0.39	16.16 ± 0.71	47.00 ± 2.00
300 mg/kg bw/day	Day 90	8.75 ± 0.35	16.85 ± 0.34	48.00 ± 0.82

* Significantly different from control ($p<0.05$)

2. Clinical chemistry findings

At day 45 mean globulin levels were significantly decreased in group 3 and 4 males when compared with the control. At the same time mean albumin/globulin ratios were significantly elevated in group 4 males (see Table 5.8.1-15). At day 45 and day 90 the mean for the level of alkaline phosphatase was significantly increased in group 4 males. At day 90 group 3 and 4 females showed a statistically significant difference in mean values for alkaline phosphatase. Mean AST values for males increased with dosage level at day 90, which was statistically significant for group 3 and 4 males. Likewise, ALT levels were increased with dosage level, being significant for group 4 males (see Table 5.8.1-16).

Table 5.8.1-15: Selected clinical chemistry findings in rats administered M310I018 for 45 days (group means)

	Males				Females			
Dose [mg/kg bw/d]	0	50	150	300	0	50	150	300

* Significantly different from control ($p<0.05$)

3. Urinalysis
Urinalysis revealed no trends or abnormalities.

E. NECROPSY

1. Organ weight
Absolute liver weights, liver/body and liver/brain weight ratios increased with dosage level for both male and female rats. Mean values for absolute liver weight, liver/body and liver/brain weight ratios were significantly different for group 4 males and females compared to the control. Absolute kidney weights, kidney/body and kidney/brain weight ratios also increased with dosage level for both male and female rats. Group 3 and 4 females showed significantly elevated means for absolute kidney weights. Statistically significant differences in mean values for kidney/body weight ratios occurred between group 4 and control males. Group 3 and 4 males and females had significantly elevated mean values for kidney/brain weight ratios compared to control males and females. No further trends were observed.

Table 5.8.1-17: Mean absolute organ weights in rats administered M310I018 for 90 days (group means)

	Terminal bw [g]	Liver [g]	Kidney [g]
	Males		
Control	366 ± 48	12.51 ± 2.73	2.58 ± 0.50

* Significantly different from control ($p<0.05$)

2. Gross and histopathology

Gross lesions:
All macroscopic findings occurred either individually and were considered to be incidental or spontaneous in origin and without any relation to treatment.

Histopathology
The non-neoplastic histopathologic observations were generally those of spontaneous lesions occurring in albino rats, and included inflammatory lesions of the esophagus and periesophageal tissues, pericarditis, and inflammation of the myocardium. The large intestines contained evidence of parasits infection (nematodiasis). The liver contained evidence of parasitic migration (inflammation, focal, granulomatous). The eyes from several rats in each of the four treatment groups were noted during the study period to have corneal opacities, at histopathologic examinations these were determined to be vacuolar keratitis. The kidneys in all treatment groups contained small numbers of proteinaceous casts located in the proximal and distal convoluted tubules. The casts were observed with approximately equal frequency in all treatment groups. The urinary bladders of the male animals contained proteinaceous plugs composed of aggregates of sperm and prostate gland secretions.

Treatment with M310I018 did not induce a dose-related increase in neoplastic or non-neoplastic lesions in the examined tissues. No differences were observed between control groups and high dose treated animals regarding lesions in the reproductive or nervous system, respectively.

III. CONCLUSIONS

The oral administration of M310I018 to male and female Sprague-Dawley rats over a period of 90 days did not reveal test substance related adverse signs of systemic toxicity at dose levels of 50, 150, or 300 mg/kg bw/d. Increased liver and kidney weights were observed at mid and high dose level, but were considered to be related to increased metabolic activation rather than to adverse effects.
Therefore, under the conditions of the present study the no observed effect level (NOEL) was 50 mg/kg bw/day in male and female animals.
Supplemental information from open literature about toxicokinetics of pyrethroid metabolits in males and female rats was evaluated in the DAR or lambda-cyhalothrin [see Ueyama et al., 2010; discussed in Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 125-129] indicating that females eliminate M310I018 more rapid than male rats.

Information with regard to the endocrine potential of M310I018 was gathered from the open literature. A summary table of the available literature is provided in Table 5.8.1-20 below. The literature is however described in more detail in the chapter CA 5.8.3.

Only in vitro studies are available for M310I018 with regard to endocrine related mode of action. According to Jin et al., 2010 [see CA 5.8.3/17 2010/1232199] rather no, at most weak estrogenic effects on mRNA expression level for ER and pS2 were seen in MCF-7 cells. Furthermore no proliferation of MCF-7 cells was induced. PBAld showed estrogenic activity in the low micromolar range in a transactivation assay in yeast cells (McCarthy et al., 2006; [see CA 5.8.3/16 2006/1051135]), but no activity in mammalian MCF-7 cells (Tange et al., 2014; [see CA 5.8.3/9 2014/1242695]). In addition, anti-androgen activity in CHO cells was found to be rather weak, with an IC_{20} in a concentration range of 0.17 µM but an IC_{50} at 27.40 µM which is not considered anymore relevant for human exposure (Tange et al., 2014; [see CA 5.8.3/9 2014/1242695]).

Based on the lack of pronounced estrogenic or anti-androgenic activity in vitro in mammalian cells no further in vivo studies were considered necessary.

Table 5.8.1-20: Literature data for endocrine activity of M310I018

Endpoint	Test system with endpoint	Endocrine activity	Positive control	Reference DocID
In vitro assays				
ER-dependent regulation of mRNA expression	Estrogen Receptor (ER) mRNA levels in MCF-7	Estrogenic. not active RIE: 7.3% (at 1µM)	E2: RIE set to 100% at 1 nM	Jin et al., 2010 2010/1232199
ER-dependent regulation of mRNA expression	pS2 mRNA levels in MCF-7	Estrogenic weak active RIE: 12.5% (at 1µM)	E2: 4-fold ↑ (1 nM)	Jin et al., 2010 2010/1232199
ER-activation	hER-α transactivation in Yeast (lacZ)	ER-agonist: Active EC_{50}: 4.8±3.4E-6M	Agonist: E2: EC_{50}: 0.4±0.2E-9M	McCarthy et al., 2006 2006/1051135
ER-activation	hER transactivation in MCF-7 cells (Luciferase)	ER-agonist: Not active up to 100 µM ER-Antagonist: Not tested	Agonist: E2: EC_{20}: 2.4E-8M	Tange et al., 2014 2014/1242695
ER-dependent proliferation	E-Screen (MCF-7)	Proliferative effect: not acive	E2: 1 nM PE: 2.12 RPE: 100%	Jin et al., 2010 2010/1232199
AR-activation	hAR transactivation in CHO cells (Luciferase)	AR-agonist: not tested AR-antagonist: active IC_{20}: 0.17E-6 M IC_{50}: 27.4E-6M	Androgen activity: DHT: 1E-10M Antagonist: Flutamide: IC_{20}: 0.16E-6 M IC_{50}: 0.62E-6M	Tange et al., 2014 2014/1242695

E2: 17 beta-Estradiol; EE: ethinyl estradiol; 4HO-TAM: 4-Hydroxy-tamoxifen; DHT: Dihydrotestostereon; PE: Proliferative effect; RPE: relative proliferative effect calculated as the ratio (PE-1) of the test chemical over (PE-1) of E2 (x 100); RIE: The relative inductive efficiency (RIE) is the ratio between the maximal up-regulation of pS2 expression level by the test compound to that of E2 (x100) or the relative inhibitory effciency of down-regulation of ERalpha expression level by the test compound compared to that of E2 (x 100); EC50/IC20/IC50: Effect concentratio /Inhibitor concentration at which 50% increase /20%/50%decrease is found compared to control;

Toxicological evaluation of M310I018

Acute toxicity studies indicate that M310I018 is toxic when inhaled, harmful when swallowed and is a skin sensitizer. M310I018 is practically not toxic by the dermal route and is not irritating to skin and eye but may be a skin sensitizer.

The QSAR evaluation of M310I018 is of low to moderate reliability. The one identified structural alersts was not supported by the other models applied.

For M310I018 results several in vitro and in vivo genotoxicity studies were available. Based on the whole datapackage and in particular considering the most relevant studies discussed in detail in section b above there is no evidence for genotoxicity of M310I018.

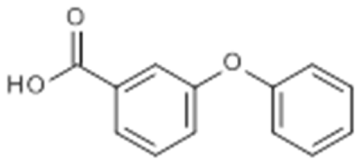
M310I018 was investigated for its estrogenic and anti-androgenic potential and is considered to show no relevant endocrine potential in vitro.

Results from a 90-day study in rats showed increased liver and kindey weights considered to be related to increased metabolic activation rather than to an adverse effect. The NOEL of the study was 50 mg/kg bw/day

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day

M310I018 is considered to be not genotoxic. The available toxicological database does not provide any concern for M310I018. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the relevant TTC-threshold. Therefore, M310I018 is considered to be **not toxicologically relevant**.

M310I011 (other denominators: PBA, PBAcid, m-PB acid, 3-PB acid, Reg.No. 130213, CAS-No. 3739-38-6, WL 44607, CL206128)



M310I011 is a metabolite found in rats, livestock (goat, hen) and in crops (wheat).

a. QSAR Predicitions on M310I011

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 11 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]
There were **no** Ames mutagenicity alerts for M310I011 or in-silico generated metabolites and no structural alerts were received. In all cases the structures were out of domain. None of 8 in-silico metabolites was predicted positive, including M310I010 the glycine conjugate of M310I011 and a potential structure for M310I013 the hydroxylated derivative of M310I011.
For in-vitro chromosome aberration there were **no** genotoxicity alerts for M310I010 or in-silico generated metabolites and no structural alerts were received. None of 8 in-silico metabolites was predicted positive, including M310I010 the glycine conjugate of M310I011 and a potential structure for M310I013 being equal to M310I025 the para-hydroxylated derivative of M310I011.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 11 of report, [see KCA 5.8.1/5 2014/1289317]]
M310I011 was in the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The prediction is based on 6 molecules, of which three were predicted 'mutagen', which was true for two of them regarding the experimental value. Three molecules were predicted and actual 'non-mutagen'. The similarity of the molecules in the data set to M310I011 is quite good as indicated by similarity factors of 0.850 to 0.892. Also the concordance of the total underlying database was high (1.0) and thus is very robust.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 11 of report, [see KCA 5.8.1/5 2014/1289317]]
M310I011 was in the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The similarities and the concordance scores correspond to the values of the CAESAR model (see above).

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 11 of report, [see KCA 5.8.1/5 2014/1289317]]
M310I011 was in the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The prediction is based on 6 molecules, of which one was predicted and actual 'mutagen'. The similarity to PBAcid (Reg.No.) of the molecules in the data set is moderate as indicated by similarity factors of 0.798 to 0.846. The concordance of the total underlying database was high (1.0) and thus is very robust.

Conclusion on QSAR evaluations
No conclusive structural alert was identified for M310I011.

Toxicity studies on M310I011

Report:	CA 5.8.1/36 Matsumoto K., 2000a CL206, 128: Reverse mutation test AL-435-010
Guidelines:	EPA 870.5100, JMAFF 59 NohSan No 4200
GLP:	yes (certified by Ministry of Agriculture, Forestry and Fisheries of Japan, Japan)

Executive Summary

S. typhimurium (strains TA98, TA 100, TA 1535 and TA 1537) and E. coli strain WP2 uvrA were exposed to M310I011; batch: AC11303-61, purity: 99%) using dimethylsulfoxide (DMSO) as a solvent in the presence and absence of metabolic activation in two independent experiments. Triplicate plates were used per dose and per test condition. Vehicle and positive controls were included in each experiment. In the first pre-incubation test the test substance was used at concentrations of 21, 62, 185, 556, 1667, and 5000 µg/plate. In the second pre-incubation test the test substance was used at concentrations of 156, 313, 625, 1250, 2500, and 5000 µg/plate. In both experiments a weak bacteriotoxic effect was observed depending on the strain and test conditions at concentrations from about 1250 µg/plate onward. Precipitation of the test substance did not occur up to the highest tested concentration.
A biologically relevant increase in the number of revertant colonies was not noticed in any of the strains tested in presence or absence of metabolic activation in any of the experiments. The positive controls induced the appropriate response in the corresponding strains, thus demonstrating the sensitivity of the test system.
According to the results of the study M310I011 was not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions of the study.
(Doc ID AL-435-010)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material	CL206,128, 3-Phenoxybenzoic acid (Metabolite of BAS 310 I, Alpha-Cypermethrin)
Description:	Solid, white
Lot/Batch #:	AC11303-61
Purity:	99%
2. Vehicle:	Dimethylsulfoxide (DMSO)

3. Control Materials:

Vehicle control: The vehicle control with and without S-9 mix only contained the vehicle used for the test substance at the same concentration and volume for all tester strains.

Solvent/final concentration: 100 µL/plate

Positive control compounds tested without addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2)	DMSO	0.01 µg/plate
TA 1535	Sodium azide (NaN_3)	Water	0.5 µg/plate
TA 1537	9-Aminoacridine (9-AA)	Water	80 µg/plate
TA 98	AF-2	DMSO	0.1 µg/plate
WP2 uvrA	AF-2	DMSO	0.01 µg/plate

Positive control compounds tested with addition of metabolic activation system:

Strain	Mutagen	Solvent	Concentration
TA 100	2-aminoanthracene	DMSO	1.0 µg/plate
TA 1535	2-aminoanthracene	DMSO	2.0 µg/plate
TA 1537	2-aminoanthracene	DMSO	2.0 µg/plate
TA 98	2-aminoanthracene	DMSO	0.5 µg/plate
WP2 uvrA	2-aminoanthracene	DMSO	10.0 µg/plate

4. Activation:

S9 was produced from the livers of induced male Sprague-Dawley rats (pre-treatment with phenobarbital and β-naphthoflavone). The S9-mix was prepared freshly prior to each experiment. For this purpose, a sufficient amount of S9-fraction is thawed at room temperature and 1 volume of S9-fraction is mixed with 9 volumes of S9-supplement (cofactors). This preparation, the so-called S9-mix, was kept on ice until used.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	100 mM
Glucose 6-phosphate	5 mM
NADPH	4 mM
NADH	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9	10 %

To demonstrate the efficacy of the rat liver S9 mix in this assay, the S9 batch was characterized with benzo(a)pyrene.

5. Test organisms: S. typhimurium strains: TA98, TA100, TA1535, TA1537
E. coli: WP2 uvrA

Salmonella typhimurium: The Salmonella strains are checked for the following characteristics at regular intervals: deep rough character (rfa); UV sensitivity (uvrB); ampicillin resistance (R factor plasmid). E. coli WP2 uvrA is checked for UV sensitivity.

Histidine and tryptophan auxotrophy is automatically proven in each experiment via the spontaneous rate.

6. Test concentrations:

Pre-incubation assay: In the first test triplicate plates were prepared for each concentration (neg. control; 21, 62, 185, 556, 1667, and 5000 µg/plate and positive controls) and condition (i.e. with and without S9) for all tester strains.
In the second experiment triplicate plates were prepared for each concentration (neg. control; 156, 313, 625, 1250, 2500, and 5000 µg/plate and positive controls) and condition (i.e. with and without S9) for all tester strains.

B. TEST PERFORMANCE:

1. Dates of experimental work: 04-Oct-1999 to 04-Nov-1999

2. Dose range finding test:
In order to assess bacteriotoxic effects, a dose range finding test was conducted on all strains according to the pre-incubation methods with and without metabolic activation system at 20, 78, 313, 1250, and 5000 µg/plate. A singe plate was applied for each dose level and duplicates were applied for solvent and positive control groups.

3. Pre-incubation assay:
100 µL of test solution or vehicle, 0.1 mL bacterial suspension and 0.5 mL S9 mix or phosphate buffer were incubated at 37°C for about 20 minutes. Subsequently, 2 mL of soft agar was added and, after mixing, the samples are poured onto the agar plates.
After incubation in the dark for 48 hours at 37°C each plate was checked for precipitates and status of the background lawn. Revertant colonies were counted. Means and standard deviations were calculated.

4. Statistics:
No special statistical tests were performed.

5. Evaluation criteria:
The test chemical is considered positive in this assay if the following criteria are met:

A dose-related and reproducible increase in the number of revertant colonies, i.e. about doubling of the spontaneous mutation rate in at least one tester strain either without S9 mix or after adding a metabolizing system.

A test substance is generally considered non-mutagenic in this test if:

The number of revertants for all tester strains was within the solvent control range under all experimental conditions in two experiments carried out independently of each other.

II. RESULTS AND DISCUSSION

A. TOXICITY

A bacteriotoxic effect was observed in all strains at 5000 µg/plate in the dose range finding test. In the main experiments toxicity at 5000 µg/plate was observed in the S. typhimurium strains of TA100 and TA1535 and in E. coli WP2 uvrA and at dose levels of 1667 µg/plate or more in TA98 and TA1537 in the absence of S9 mix. In the presence of S9 mix bacteriotoxicity was observed at 2500 µg/plate or more in Salmonella strains TA100, TA1535, and TA98 and in E. coli WP2 uvrA and at 1250 µg/plate or more in TA1537.

B. MUTATION ASSAYS

In the 2 independent preincubation experiments with and without metabolic activation no biologically relevant increase in number of revertants was observed in any strain tested [see Table 5.8.1-21]. The positive controls yielded revertant numbers in a range expected for the respective strains and thus demonstrated the sensitivity of the test system.

Precipitation was not observed up to the maximum concentration.

III. CONCLUSION

According to the results of the present study, M310I011 is not mutagenic in the Salmonella typhimurium / Escherichia coli reverse mutation assay under the experimental conditions applied.

Report: CA 5.8.1/37
[redacted] 2014a
3-Phenoxybenzoic acid (metabolite of BAS 310 I, Alpha-Cypermethrin): Micronucleus test in Chinese Hamster V79 cells in vitro
2014/1168736

Guidelines: OECD 487 (2010), Commission Regulation EU No. 640/2012 of 06 July 2012 - B.49: In vitro Mammalian Cell Micronucleus Test

GLP: yes
(certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Remark Oct-2015: The pending stability analysis (Doc ID 2015/1029517) is included and highlighted**.**

Executive Summary

M310I011 (Batch: AC12251-34; Purity: 100%) was tested for chromosomal damage (clastogenicity) in Chinese Hamster V79 cells using the *in vitro* micronucleus test method. For this purpose, V79 cells were seeded in Quadriperm dishes and were incubated with the test substance at concentrations of 4.2 to 2142 µg/mL (≙10 mM) in the presence or absence of S9 mix. The cells were treated for 4 h in the presence or absence of S9 mix and for 24 h in the absence of S9 mix. After the incubation period cells were fixed and stained with Giemsa. At least 1000 cells per culture were scored for cytogenetic damage on coded slides and a proliferation index was determined for evaluation of cytotoxicity. No precipitation of the test item in the culture medium was observed, except for the highest applied concentration (2142 µg/mL) in Experiment IIB in the absence of S9 mix. No relevant influence on osmolarity or pH value was observed. In Experiment I in the absence and presence of S9 mix and in Experiment IIA in the presence of S9 mix, no cytotoxicity was observed up to the highest applied concentration. In Experiment IIA and IIB in the absence of S9 mix moderate cytotoxicity of approx. 40% of control was observed at the highest evaluated concentration. In the incubation with S9 mix and the long-term incubation without S9 mix significant increases of the micronucleus rate was observed. No increase of the micronucleus rate was observed in the short-term exposure in the absence of S9 mix. The positive control chemicals mitomycin C, griseofulvin and cyclophosphamide led to the expected increase in the micronucleus rate, thus demonstrating the sensitivity of the test system.
In conclusion, it can be stated that under the experimental conditions reported, the test item induced micronuclei as determined by the *in vitro* micronucleus test in Chinese hamster *V79* cells. Therefore, M310I011 is considered to be mutagenic in this *in vitro* micronucleus test, when tested up to the highest evaluable or the highest required concentration.

(DocID 2014/1168736)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: 3-phenoxybenzoic acid (Metabolite of BAS 310 I)
Description: solid (powder) / white
Lot/Batch #: AC12251-34
Purity/content: 100%
Stability of test compound: The test item was stable under storage conditions over the study period (expiry date 01 December 2020). The test item was stable in the vehicle for at least 4 hours (see separate report Doc ID 2015/1029517).

2. Vehicle used: DMSO (0.5%)

3. Control Materials:
Negative: No negative control was employed in this study.
Vehicle control: DMSO
Positive control (with S9): Cyclophosphamide (CPA), 15 µg/mL
Positive control (without S9): Mitomycin C, 0.1 µg/mL; Griseofulvin, 8 µg/mL

4. Activation: S9 was produced from the livers of rats (pre-treatment with phenobarbital and β-naphthoflavone). The S9-mix was prepared freshly prior to each experiment.

The S9-mix was prepared immediately before use and had the following composition:

Component	Concentration
Phosphate buffer (pH 7.4)	100 mM
Glucose 6-phosphate	5 mM
NADPH	4 mM
NADH	4 mM
KCl	33 mM
$MgCl_2$	8 mM
S9 (final protein concentration)	0.75 mg/mL

To demonstrate the efficacy of the rat liver S9 mix in this assay, the S9 batch was characterized with benzo(a)pyrene and 2-aminoanthracene.

5. Test system:

Cell line:	V79 (Chinese hamster cells) Each batch of cells is checked for mycoplasma contamination and karyotype stability.
Culture media:	MEM containing Hank´s salts, L-glutamine and Hepes (25 mM). Additionally, the medium was supplemented with 10% fetal calf serum (FCS) and 1% Pen/Strep (100 U/mL and 100 µg/mL). During the exposure period in the presence of S9 mix MEM medium without FCS was used.
Culture conditions:	Cells were grown with 1.5% CO_2 at 37°C and ≥ 90% relative humidity. Subculturing was performed twice weekly (doubling time 12-14 h). For the experiment, the cells were seeded into Quadriperm dishes containing microscopic slides. Into each chamber 1.0 x 10^5 – 1.5 x 10^5 cells were seeded.

6. Test compound concentrations:

Experiment I (4 h, ±S9 mix):	4.2, 8.4, 16.7, 33.5, 66.9, 133.9, 267.8, **535.5, 1071, 2142** µg/mL
Experiment IIa (24 h, -S9 mix):	4.2, 8.4, 16.7, 33.5, 66.9, **133.9, 267.8, 535.5**, 1071, 2142 µg/mL
Experiment IIb (24 h, -S9 mix):	33.5, 66.9, **133.9, 267.8, 401.7, 535.5, 669.4, 803.3**, 1071, 2142 µg/mL
Experiment IIa (4 h, +S9 mix):	**535.5, 803.3, 1071, 1606.5, 2142** µg/mL

Evaluated experimental points are shown in bold characters

B. TEST PERFORMANCE

1. Dates of experimental work: 15-Jul-2014 to 23-Oct-2014

2. Preliminary experiment:

A preliminary cell growth inhibition (determination of proliferation index) was performed to determine the concentrations to be used in the main experiment. The experimental conditions in this pre-experimental phase were identical to those required and described for the mutagenicity assay.

The pre-test was performed with 10 concentrations of the test item separated by no more than a factor of √10 and a solvent and positive control. All cell cultures were set up in duplicate. Exposure time was 4 hrs (with and without S9 mix). The preparation interval was 24 hrs after start of the exposure. Since the cultures fulfilled the requirements for cytogenetic evaluation, this preliminary test was designated experiment I.

3. Micronucleus test:

Pulse exposure:

The culture medium of exponentially growing cell cultures was replaced with serum-free medium containing the test item. For the treatment with metabolic activation 50 µL S9 mix per mL culture medium was added. After 4 hours the cultures were washed twice with "Saline G" (pH 7.2) containing 8000 mg/L NaCl, 400 mg/L KCl, 1100 mg/L glucose•H_2O, 192 mg/L Na_2HPO_4•2 H_2O and 150 mg/L KH_2PO_4. The cells were then cultured in complete medium containing 10 % (v/v) FBS for the remaining culture time of 20 hours.

Continuous exposure (-S9):

The culture medium of exponentially growing cell cultures was replaced with complete medium containing 10 % (v/v) FBS including the test item. The medium was not changed until preparation of the cells.

Preparation of micronuclei:

The cells were treated on the slides in the chambers with deionised water for 1 – 1.5 min at 37 °C. Afterwards the cells were fixed twice with a mixture of methanol and glacial acetic acid (3+1 parts, respectively) containing 1.25 % formaldehyde. The slides were stained with Giemsa, mounted after drying and covered with a cover slip. All slides were labelled with a computer-generated random code to prevent scorer bias.

Evaluation of cytotoxicity and cytogenetic damage:

The area of the micronucleus should not extend the third part of the area of the main nucleus. Per culture at least 1000 cells from clones with 2 - 8 cells were scored for cytogenetic damage on coded slides. The frequency of micronucleated cells was reported as % micronucleated cells.
Cytotoxicity was assessed via counting the number of clones consisting of 1 cell (c1), 2 cells (c2), 3 - 4 cells (c4), and 5 - 8 cells (c8) among the cells that were scored for the presence of micronuclei. These clusters represent the cells that have divided 1, 2, or 3 times within the experiment. From these data, a proliferation index (PI) is calculated (see formula below). Only those cultures were evaluated which showed a PI > 1.3, in order to guarantee a sufficient cell proliferation during treatment and recovery.

$$PI = \frac{(c1 \times 1) + (c2 \times 2) + (c4 \times 3) + (c8 \times 4)}{(c1 + c2 + c4 + c8)}$$

PI: Proliferation index
cx: Number of clones with x cells (with x: 1, 2, 4, or 8)

4. Statistics:
Many experiments with Chinese Hamster *V79* cells have established a range of micronucleus frequencies acceptable for control cultures. The current historical data range together with the statistical significance, confirmed by the Chi square test ($\alpha < 0.05$), should be considered for classification of the test item.

5. Evaluation criteria:
The micronucleus assay is considered acceptable if it meets the following criteria:

a) The rate of micronuclei in the solvent controls falls within the historical laboratory control data range.
b) The rate of micronuclei in the positive controls is statistically significant increased.
c) The quality of the slides must allow the evaluation of a sufficient number of analyzable cells.

A test item can be classified as non-mutagenic if:
- the number of micronucleated cells in all evaluated dose groups is in the range of the historical laboratory control data and
- no statistically significant or concentration-related increase of the number of micronucleated cells is observed in comparison to the respective solvent control.

A test item can be classified as mutagenic if:
- The number of micronucleated cells exceeds both the value of the concurrent negative control and the range of the historical negative control data.
- A significant, dose-related and reproducible increase in the number of cells containing micronuclei is observed

If the above mentioned criteria for the test item are not clearly met, the test item is classified as equivocal or a confirmatory experiment may be performed. However, results may remain questionable regardless of the number of times the experiment is repeated.

II. RESULTS AND DISCUSSION

No precipitation of the test item in the culture medium was observed, except for the highest applied concentration (2142.0 µg/mL) in Experiment IIB in the absence of S9 mix (see Table 5.8.1-22 and Table 5.8.1-23). No relevant influence on osmolarity or pH value was observed.
In Experiment I in the absence and presence of S9 mix and in Experiment IIA in the presence of S9 mix, no cytotoxicity was observed up to the highest applied concentration. In Experiment IIA and IIB in the absence of S9 mix moderate cytotoxicity of approx. 60 % of control was observed at the highest evaluated concentration.

In Experiment I (4 h exposure) in the absence of S9 mix no relevant increase in micronucleated cells was observed. In Experiment IIA (24 h exposure) in the absence of S9 mix one statistically significant increase in micronucleated cells (2.20 % micronucleated cells), clearly above the range of the laboratory historical control data (0.15 – 1.50 % micronucleated cells), was observed after treatment with 535.5 µg/mL. In Experiment IIB (24 h) in the absence of S9 mix statistically significant increases in micronucleated cells (4.05, 2.75 and 2.50 %) were observed after treatment with 401.7, 535.5 and 669.4 µg/mL but showed no dose response relationship.. The concentrations ranging from 267.8 to 803.3 µg/mL showed increases above the range of the laboratory historical control data (0.15 – 1.50 % micronucleated cells). Although without a strong evidence in relation to dose-response relationship they confirm the isolated positive finding of Experiment IIA.

In Experiment I in the presence of S9 mix one statistically significant increase in micronucleated cells (4.08 % micronucleated cells), clearly above the range of the laboratory historical control data (0.05 – 1.70 % micronucleated cells), was observed after treatment with 1071.0 µg/mL. However, no such effect was seen in the next higher concentration of 2014 µg/ml. In Experiment IIA in the presence of S9 mix all evaluated concentrations showed statistical significant increases due to the low response of the solvent control (0.15 %), but these values (0.60 – 1.40 % micronucleated cells) were clearly within the range of the laboratory historical solvent control data (0.05 – 1.70 % micronucleated cells) and no dose-dependency was observed. Thus the positive finding of Experiment I with metabolic activation could not be confirmed.

Either Griseofulvin (8.0 µg/mL), MMC (0.1 µg/mL) or CPA (15.0 µg/mL) were used as positive controls and showed distinct increases in cells with micronuclei.

* **Number of micronucleated cells statistically significantly higher than corresponding control values (Chi square test, p< 0.05)**

‡ clearly within the range of the laboratory historical solvent control data (0.05 – 1.70 % micronucleated cells); statistical significance due to low concurrent solvent control

III. CONCLUSION

In conclusion, it can be stated that under the experimental conditions reported, the test item induced micronuclei as determined by the *in vitro* micronucleus test in Chinese hamster *V79* cells without metabolic activation.
Therefore, **M310I011** is considered to be **mutagenic** in this *in vitro* micronucleus test, when tested up to the highest evaluable or the highest required concentration.

Executive Summary

M310I011 (Batch: AC12251-34; Purity: 100%) was tested for its ability to induce micronuclei in bone marrow cells of NMRI mice. For this purpose, the test substance, suspended in PEG 400, was administered once orally to groups of 7 male mice at dose levels of 500, 1000 and 2000 mg/kg body weight in a volume of 10 mL/kg body weight. The vehicle served as negative and cyclophosphamide as positive control. The animals were sacrificed 24 or 48 (additional high dose and vehicle group) hours after the administration and the bone marrow of the two femora was prepared. After staining of the preparations, 6000 polychromatic erythrocytes were evaluated per animal and investigated for micronuclei. To describe a cytotoxic effect the ratio between polychromatic and normochromatic erythrocytes was determined in the same sample and expressed in polychromatic erythrocytes per 500 erythrocytes.

The highest dose (2000 mg/kg b.w.; maximum guideline-recommended dose) was estimated by three pre-experiments to be suitable. No substantial differences between sexes in toxicity were observed. Bioavailability of the test substance in the mouse was proven in plasma samples of the treatment groups, which were dosed with 2000 mg/kg bw 2- and 4 hours after administration.

In the main study, conducted only in males, one male had to be euthanized after treatment with this dose due to severity of clinical symptoms. The test item induced systemic toxicity confirmed the systemic distribution of the compound. Thus, bioavailability of the test item under the tested conditions is given. After treatment with the test item the number of PCEs was not substantially decreased as compared to the mean value of PCEs of the vehicle control thus indicating that M310I011 did not exert any cytotoxic effects in the bone marrow. A statistically significant increase in micronuclei frequency was detected in both the low dose and the 24 h high dose group, respectively, when compared to the corresponding vehicle control group. However this was considered to be not biologically relevant, since all values obtained were very well within the range of historical vehicle control data. Moreover, no dose response relationship was observed. The positive control cyclophosphamide administered orally was used as positive control which showed a substantial increase of induced micronucleus frequency.

In conclusion, it can be stated that under the experimental conditions reported, M310I011 did not induce micronuclei as determined by the micronucleus test with bone marrow cells of the mouse.

(BASF DocID 2015/1001101)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: 3-phenoxybenzoic acid
(metabolite of BAS 310 I, Alpha-Cypermethrin)

Description:	Solid, white
Lot/Batch #:	AC12251-34
Purity:	100% (tolerance ± 1.0%)
Stability of test compound:	The stability of the test substance under storage conditions throughout the study period was guaranteed until 01 Dec 2020 as indicated by the sponsor. Stability in solvent was determined indirectly by concentration control analyses (see separate report Doc ID 2015/1003984).
Vehicle used:	PEG 400

2. Control Materials:

Negative:	No negative control was employed in this study.
Vehicle control:	Corn oil
Positive control:	Cyclophosphamide (CCP) 40 mg/kg bw (10 mL/kg bw), dissolved in sterile water

3. Test animals:

Species:	Mice
Strain:	NMRI
Sex:	Males for the main study; males and females for the range finding study
Age:	6 - 10 weeks
Mean body weight at dosing:	36.2 ± 2 g
Source:	Charles River Laboratories, Research Models and Services Germany GmbH, Sulzfeld, Germany
Number of animals per dose:	
Range finding study:	1000 mg/kg bw: 2 males/4 females
	2000 mg/kg bw: 2 males/2 females
Micronucleus assay:	7 males/dose in test group
	5 males/dose in control groups
Acclimation period:	at least 5 days
Diet:	Pelleted standard diet (certified), ad libitum
Water:	Tap water, ad libitum
Housing:	During the study the mice were housed individually in Makrolon cages (Type II) with wire mesh top

4. Environmental conditions:

Temperature:	20 - 24 °C
Humidity:	45 - 65%
Air changes:	frequency not indicated (fully air-conditioned rooms)
Photo period:	12-hour light-dark cycle (06:00 a.m. - 06:00 p.m., 06:00 p.m. - 06:00 a.m.)

5. Test compound doses:

Range finding test:	1000 and 2000 mg/kg bw
Micronucleus assay:	500, 1000 and 2000 mg/kg (at 24 h sampling) 2000 mg/kg bw (at 48 h sampling) The test substance was administered once by oral gavage using an application volume of 10 mL/kg.

B. TEST PERFORMANCE

1. Dates of experimental work: 19-Nov-2014 to 17-Dec-2014

2. Preliminary range finding test:

In a pretest for the determination of the acute oral toxicity, male and female animals were treated once by oral gavage with a test substance dose of 1000 or 2000 mg/kg bw.

3. Micronucleus test:

Treatment

Groups of male mice were treated once with the vehicle or 500, 1000 or 2000 mg test substance/kg bw by oral gavage for the 24-h sampling period. Additional test groups treated with the vehicle control and the high dose were used for the second sampling period (48-h). The application volume was 10 mL/kg bw and the volume to be applied was calculated based on actual weight on the day of administration. The positive control substance CCP was administered once by oral gavage (CCP). The animals of all dose groups, except the positive control, were examined for acute toxic symptoms at intervals of around 0-1 h, 2-4 h, 5-6 h, 24 h, and/or 48 h after administration of the test item. Sampling of the bone marrow was done 24 and 48 hours after treatment, respectively.

Preparation of the animals

The animals were sacrificed using CO_2 followed by bleeding. The femora were removed, the epiphyses were cut off and the marrow was flushed out with foetal calf serum using a syringe. The cell suspension was centrifuged at 1500 rpm (390 x g) for 10 minutes and the supernatant was discarded. A small drop of the re-suspended cell pellet was spread on a slide. The smear was air-dried and then stained with May-Grünwald/Giemsa. Cover slips were mounted with EUKITT. At least one slide was made from each bone marrow sample.

Analysis of cells

Evaluation of the slides was performed using NIKON microscopes with 100x oil immersion objectives. Per animal 6000 polychromatic erythrocytes (PCE) were analysed for micronuclei. To describe a cytotoxic effect the ratio between polychromatic and normochromatic erythrocytes was determined in the same sample and expressed in polychromatic erythrocytes per 500 erythrocytes. The analysis was performed with coded slides.

4. Statistics:

Statistical methods (nonparametric Mann-Whitney test) were used as an aid in evaluating the results, except for the high dose group at the 48-h sampling time point, for which statistical significance was evaluated by means of the one-way Analysis of Variance (ANOVA)

5. Acceptance and evaluation criteria:

Acceptance criteria

The study is considered valid as the following criteria are met:
- at least 5 animals per group could be evaluated.
- PCE to erythrocyte ratio was not less than 20 % of the negative control.
- the positive control shows a statistically significant and biological relevant increase of micronucleated PCEs compared to the vehicle control.

Evaluation criteria

A test item is classified as mutagenic if it induces either a dose-related increase or a clear increase in the number of micronucleated polychromatic erythrocytes in a single dose group above the laboratory's historical solvent control data range. Statistical methods (nonparametric Mann-Whitney test) were used as an aid in evaluating the results, if necessary. However, the primary point of consideration is the biological relevance of the results.
A test item that fails to produce a biological relevant increase in the number of micronucleated polychromatic erythrocytes is considered non-mutagenic in this system.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The stability of the test substance in the vehicle is confirmed indirectly by dose formulation analytics (see separate report Doc ID 2015/1003984, BASF study code 04Y0418/01Y017). The homogeneity of the test substance in the vehicle was guaranteed by constant stirring and moderate heating (< 40°C) of the formulation directly before each dosing occasion and by analytical determination of 3 individual samples of each concentration. The mean concentration of these three samples were 42.1, 85.2 and 169.4 mg/g at nominal concentrations of 50; 100 and 200 mg/g, respectively. Thereby, the values are in the range of ± 15 % of the nominal concentration range and thereby acceptable for liquid test substance preparations.

Bioavailability of the test substance in the mouse was shown in plasma samples of the treatment groups which were dosed with 2000 mg/kg bw 2 and 4 hours after administration (see separate report Doc ID 2015/1032402, BASF study code 06Y0418/01Y018).

B. MICRONUCLEUS ASSAY (PRELIMINARY TEST)

In the pretest for the determination of the acute oral toxicity in males and females, the animals were treated with the test substance at doses of 1000 or 2000 mg/kg bw. Ruffled fur was observed in the majority of animals of the pretest. Partially closed eyes and abdominal posture were incidentally seen in a single animal each at one time point only. One female animal died at 1 h after dosing with 1000 mg/kg bw. No substantial differences between sexes in toxicity were observed. By the use of two additional females, the mortality observed in a female animal using 1000 mg/kg b.w. was confirmed to be not sex-specific, but most probably due to individual sensitivity, so that only male animals were used in the main experiment.

C. MICRONUCLEUS ASSAY (MAIN EXPERIMENT)

Clinical examinations

The animals treated with the low dose of the test item (500 mg/kg bw) or with the vehicle control (PEG 400), respectively, did not express any clinical symptoms. In the 1000 mg/kg bw dose group slightly reduced spontaneous activity was observed in one animal at 1 h post-treatment (see Table 5.8.1-24). In the 2000 mg/kg bw dose group clinical signs observed included slightly reduced spontaneous activity, abdominal posture, eyelid closure, apathy, and convulsions. These signs were only seen 1 hour post-dosing in a few animals (1-2). One animal of the high dose group was sacrificed approximately 40 minutes after application due to tonic seizures, apathy and cyanosis.

Table 5.8.1-24: Clinical examinations in the main experiment

	hours post-treatment (males)				
Clinical symptoms	**1**	**2-4**	**6**	**24**	**48**
High dose: 2000 mg/kg b.w. (14 males at 1 to 24 h; 7 males at 48 h)					
Abdominal posture	2	0	0	0	0
Eyelid closure	1	0	0	0	0
Slightly reduced spontaneous activity	2	0	0	0	0
Apathy	1	0	0	0	0
Convulsions	1	0	0	0	0
Death*	1	0	0	0	0
Medium dose: 1000 mg/kg b.w. (7 males)					
Slightly reduced spontaneous activity	1	0	0	0	0

*animal 23 was sacrificed approximately 40 minutes after application due to tonic seizures, apathy and cyanosis

Micronucleus test results

The highest dose (2000 mg/kg b.w.; maximum guideline-recommended dose) was estimated by three pre-experiments to be suitable. In the main study one male had to be euthanized after treatment with this dose due to severity of clinical symptoms. The test item induced systemic toxicity confirmed the systemic distribution of the compound. Thus, bioavailability of the test item under the tested conditions is given. Bioavailability has been demonstrated by [redacted] 1978 in the study of the metabolism of 3-PBA and its glucoside conjugate in rats, already evaluated in the first annex I inclusion process.

After treatment with the test item the number of PCEs was not substantially decreased as compared to the mean value of PCEs of the vehicle control thus indicating that 3-phenoxybenzoic acid did not exert any cytotoxic effects in the bone marrow (see Table 5.8.1-25).

A statistically significant increase in micronuclei frequency was detected in both the low dose and the 24 h high dose group, respectively, when compared to the corresponding vehicle control group. The mean values were 0.190% ± 0.10% and 0.120% ± 0.050% for the 500 and 2000 mg/kg bw dose group, respectively. However this was considered to be not biologically relevant, since all values obtained were very well within the range of historical vehicle control data. The historical control values were 0.112% ± 0.088% for the vehicle control, ranging from 0.000% to 0.450% for the individual mean group values. Moreover, no dose response relationship was observed.

40 mg/kg b.w. cyclophosphamide administered orally was used as positive control which showed a substantial increase of induced micronucleus frequency.

Table 5.8.1-25: Summary of micronucleus test results and historical control data

Test Group	Dose (mg/kg bw)	sampling time	mean MN per 6000 PCE	SD MN per 6000 PCE	mean MN (%)	SD MN (%)	Range (per 6000 PCE)		Ratio PCE /total Ery	PCE % ratio Vehicle
							min	max		
Vehicle	0	24	2.8	1.4	0.07	0.03	2	5	0.601	100.00
Dose 1	500	24	7.7*	4.1	0.19	0.10	3	15	0.612	101.86
Dose 2	1000	24	3.4	2.7	0.09	0.06	1	8	0.607	101.03

*: statistically significant ($p<0.05$); #: the historical database is based on the evaluation of the micronucleated cells per 2000 PCE per animal. The original values for the number of MN in the individual animals (0-9 (vehicle) or 8-132 (CPP)) was adapted in the table as MN per 6000 cells.

III. CONCLUSION

In conclusion, it can be stated that during the study described and under the experimental conditions reported, the test item 3-phenoxybenzoic acid (metabolite of BAS 310 I, Alpha-Cypermethrin) **did not induce micronuclei** as determined by the micronucleus test in the bone marrow cells of the mouse.

Species differences in the metabolism of 3-phenoxybenzoic acid
CY-905-031
Guidelines: none
GLP: no

Executive Summary

In this study the metabolism of ^{14}C-M310I011 has been studied in ten mammalian and one avian species in comparison with that of benzoic acid. Animals were given the radiolabeled acids (as their Na-salts) either po (intubation for rodents, gelatin capsule for others) or by ip injection. The dose levels used were 0.1, 1, 10, and 100 mg/kg bw for M310I011 or 10 mg/kg bw for benzoic acid. M310I011 exhibits wide species diversity in its metabolism, unlike benzoic acid, of which benzoylglycine (hippuric acid) is the major urinary metabolite in all species studied. With M310I011, glycine conjugation is the major route of metabolism in three species (sheep, cat, and gerbil), whereas in the mouse the taurine conjugate is the principal metabolite. The ferret eliminates similar amounts of each of these metabolites, whereas the glycylvaline dipeptide conjugate is the major metabolite isolated from the excreta of the mallard duck. Conversely, glucuronic acid conjugates of M310I011 and its 4´-hydroxy derivative (4´-HO-PBA) are the major urinary metabolites in the marmorset, rabbit, guinea pig, and hamster; the rat appears unique in eliminating the O-sulfate conjugate of 4´-HO-PBA as the principal urinary metabolite. In most cases, where amino acid conjugates are the major excretory products, the proportions of hydroxylated metabolites present are minimal. The pattern of metabolism of M310I011 does not significantly vary with dose or route (po or ip) in the sheep, gerbil, or mouse. When administered 4´-HO-PBA, the gerbil and mouse eliminate principally glucuronide and sulfate conjugates rather than amino acid conjugate, which are only minor components (<10% of the dose) in each case. This implies that hydroxylation is a primary metabolic event in determining the eventual fate of M310I011 in many species.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

a) Radiolabelled test material:	^{14}C-3-Phenoxybenzoic acid; Label: [Phenyl-U]-^{14}C
Description:	not reported
Chemical name (IUPAC):	3-Phenoxybenzoic acid
Lot/Batch #:	not reported
Purity:	Radiochemical purity: 99.8% Specific activity: 31 µCi/mg

b)	**Radiolabelled test material**:	3-(4-hydroxyphenoxy)-[^{14}C]-benzoic acid; Label: [Phenyl-U]-^{14}C
	Description:	not reported
	Lot/Batch #:	not reported
	Purity:	Radiochemical purity: 99.6% Specific activity: 17.4 µCi/mg
c)	**Radiolabelled test material**:	^{14}C-benzoic acid; Label: [carboxy]-^{14}C
	Description:	not reported
	Lot/Batch #:	not reported
	Purity:	Radiochemical purity: >99.7% Specific activity: 465 µCi/mg

2. Test animals

Several species as indicated in Table 5.8.1-26 were investigated in the study.

Table 5.8.1-26: Supplementary data for animals used in the metabolism studies

Species			**Animals used**				
Common name	**Strain**	**Species**	**No./Sex**		**Weight**	**Radioactivity administered/animal**	**Diet**
			3PBA	**Benzoic acid**		**µCi**	
Rat	Wistar	Rattus norvegicus	4 m	3 m	250 ± 50 g	10	b
Marmorset		Calithrix jaccus	2 m	-	300 g	10	c
Hamster	Syrian	Mesocricetus auratus	3 f	3 f	150 ± 40 g	7	b
Guinea Pig	Dunkin-Hartley	Cavia porcellus	3 f	3 f	550 ± 50 g	10	d
Rabbit	New Zealand White	Oryctolagus cuniculus	4 f	3 f	3.5 ± 0.5 kg	20	e
Sheep	Welsh Mountain	Ovis ovis	2 f	2 f	21, 28 kg	20	f
Ferret		Mustela furo	4 f	3 f	700 ± 100 g	20	g
Cat	Mongrel	Felis cattus	1 m	1 m	3.2, 3.2 kg	20	g
Gerbil		Meriones libycus	3 m	3 f	60 ± 20 g	5	b
Mouse	CF1	Mus musculus	6 m	-	25 ± 3 g	2	b
Mallard Duck		Anas platyrhynchos	4 m	-	1.1 ± 0.1 kg	20	i

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: not reported

2. Animal assignment and treatment:
Animals were given the radiolabeled acids (as their Na-salts) either po (intubation for rodents, gelatin capsule for others) or by ip injection. The dose levels used were 0.1, 1, 10, and 100 mg/kg bw for M310I011 or 10 mg/kg bw for benzoic acid. For the duration of the experiments (up to 72 h), animals were housed individually (except for mice, 2 animals per cage) in appropriately sized all-glass metabolism cages (mini and standard size Metabowls for rodents; Jencons Ltd., Hemel Hempstead, Herts.) or in metal metabolism cages designed to permit the separate collection of urine and faeces.

3. Sample collection and investigations:
Samples of excreta from each cage were collected daily at room temperature and assayed as soon as possible after collection.
Where appropriate, faecal samples were extracted three times with a methanol/water (1:1, v/v) mixture by homogenization with an Ultra-Turrax homogenizer (half-maximal speed for 2 min). The homogenate (50% v/v) was centrifuged for 30 min at 4°C and 4000 g, and the supernatant fluid was analyzed by TLC. Samples (20-50 µL) of faecal supernatant and urine samples (5-30 µL) were analysed by LSC.
For separation and quantification of radiolabeled metabolites, urine (5-20 µL) was subjected to one-dimensional TLC in solvents A, B, and C, and in two dimensions in solvents A (first dimension) x B (second dimension) and BxC, followed by autoradiography and LSC. All urine samples were filtered (0.22 µm) before TLC.

II. RESULTS AND DISCUSSION

1. Elimination of radioactivity
The urinary excretion profiles for animals administered the radiolabeled carboxylic acids (10 mg/kg bw) are shown in Table 5.8.1-27. For each acid, the urine was the major route of elimination of radioactivity in all species. In most cases, 60-100% of the radioactivity administered was rapidly excreted in the urine within 24 h of dosing. The only animals in which the urinary excretion of radioactivity was relatively slow were the ferret and the cat, which excreted only 35% and 24%, respectively, of M310I011 and its metabolites within 24 h, and 45% and 57% respectively, during 3 days. Conversely, benzoic acid and its metabolites were rapidly eliminated by the cat and ferret, as they were in all other species studied. The mallard duck was also relatively slow to eliminate M310I011 and its metabolites, with 45% of the dose detected in the excreta in 24 h.

Faecal elimination appeared, in the majority of cases, to be a minor route of elimination for all compounds, accounting for <5% of the radioactivity aliminated in 72 h. The ferret, however, eliminated 11.6% of the administered radioactivity over a 72-h period in the faeces after treatment with M310I011. In case of benzoic acid, faecal elimination in this species was only 3.2% over 3 days.For those species given M310I011 over a range of dose levels (mouse, gerbil, and sheep) and by differing routes of administration (mouse and sheep), the urine remained the major route of elimination. The most significant difference observed was that in the sheep, which eliminated radioactivity more rapidly via this route after po dosing (98% in 24 h) than after ip administration (80% after 24 h). When 4´-HO-PBA (10 mg/kg bw, ip) was administered to the mouse and gerbil, more rapid urinary excretion of radioactivity was observed than that seen after administration of M310I011 under similar conditions.

Table 5.8.1-27: Urinary excretion of radioactivity following administration of ^{14}C-labeled M310I011 and benzoic acid to various species.

Species	Excretion after administration of carboxylic acid (10 mg/kg bw, ip) [% of administered dose]	
	M310I011	Benzoic Acid
Rat	68.7±5.1	88.0±1.7
Marmorset	73.3±64.7[a]	
Hamster	85.1±8.7	52.6±3.1
Guinea pig	87.8±2.4	70.8±3.7
Rabbit	67.6±1.0	78.6±9.7
Sheep	81.0, 78.4	83.5, 86.3
Ferret	34.8±5.4	53.9±2.5
Cat	24.3	80.7
Gerbil	65.1±4.0 (88.4±7.7)[b]	59.6±10.3
Mouse	67.1±8.0 (97.9±2.2)[b]	
Mallard duck	44.6±3.8 [a,c]	

a: po dose; b: ^{14}C excreted after administration of 4´-HO-P[^{14}C]BA; c: methanol-soluble fraction

2. Identification of the urinary metabolites of M310I011

Metabolite I (M310I011) was separately isolated from the urine of several species (rabbit, guinea pig, gerbil, and marmoset) hamster, marmoset, and rabbit urine by extraction with diethyl ether/ethanol (3:1, v/v) at pH 2.

Metabolite II (M310I025, 4´-HO-PBA) was isolated from hamster, marmoset, and rabbit urine by extraction with diethyl ether/ethanol.

Metabolite III (M310I010) was present in all urine samples collected, and was particularly prominent in those from cat, sheep, ferret, and gerbil. It was stable to enzymic treatment. The zone did not react with ninhydrin until concentrated HCl was added and the chromatogram was heated to 110°C. As chromatography was not effective to identify the standard substance, physical methods were applied for its characterization.

Metabolite IV (PBAglyval) was detected only in the methanol-soluble fraction of the excreta from the mallard duck, in which it was the principal metabolite.

Metabolite V (PBAgluc) was the major metabolite in several species (rabbit, hamster, guinea pig, marmoset, and mouse). It was partially (40%) hydrolyzed after treatment with β-glucuronidase, the radiolabeled aglycone being chromatographically indistinguishable from M310I011 standard, which was confirmed by EI-mass spectrum.
Metabolites VI and VII (4´-HO-PBAgluc and 4´-O-gluc-PBA):

Metabolite VIII (unknown) was the most ubiquitous unidentified metabolite, being particularly prominent in the marmorset and mouse. In urine samples from all species it had very similar chromatographic properties to those of 4´-$HOSO_2$OPBA. It was present in the urine from animals dosed with 4´-HO-PBA and, in the mouse exhibited a similar variation with dose as 4´-$HOSO_2$OPBA after administration of PBA. This suggests that this metabolite is a sulfate ester, perhaps of a dihydroxylated derivative of M310I011, which upon cleavage with sulfatase is not sufficiently stable to be characterized by TLC.
Metabolite IX (M310I014, 4´-$HOSO_2$OPBA) was the major metabolite in the rat and appeared in samples from most species. After treatment with sulfatase it was completely hydrolyzed, the aglycone being indistinguishable from metabolite II (M310I025, 4´-HO-PBA).
Metabolite X (PBAtau) was the major metabolite in the mouse and was also present, in smaller amounts, in the ferret and marmoset.

Table 5.8.1-28: Metabolic profile of urine samples from animals administered [^{14}C] M310I011 (10 mg/kg bw)

3. Identification of the urinary metabolites of benzoic acid

The metabolic profiles obtained were very similar in comparison with those derived from M310I011, but were qualitatively similar between species. Benzoylglycine (hippuric acid) was the major metabolite in all species studied. Similarly, unchanged benzoic acid was detected in all species but generally constituted <10% dose. The most complex metabolic profile was that observed in the ferret where benzoyl glucuronide was a major urinary metabolite in addition to hippuric acid. Furthermore, two minor metabolites of unknown identity were detected; these were not present in samples from any other species. Benzoylglucuronide was detected in small quantities in the rat, hamster, and guinea pig, but was absnt from other species studies.

4. Identification of urinary metabolites of (M310I025, 4´-HO-PBA) in the mouse and gerbil

In the mouse and gerbil M310I025 is principally eliminated unchanged, together with some M310I014 (4´-$HOSO_2$O-PBA) and the glucuronic acid derivatives of 4´-HO-PBA. This is in markled contrast to the pattern seen with M310I011, for which amino acid conjugates are the major urinary metabolites detected in these species (M310I010 in gerbil and PBAtau in mouse). Minor urinary components (<10%) were detected in gerbil and mouse. The chromatographic mobilities suggest that unidentified XI and XII are the glycine and taurine conjugates of 4´-HO-PBA. Due to extensive degradation following derivatisation no characterisation by means of mass spectrometry was possible.

5. The effect of variation of dose on the metabolism of M310I011 in various species

^{14}C-labeled PBA was administered ip to sheep, mice, and gerbils over a 1000-fold dose range: 0.1, 1, 10, and 100 mg/kg bw. In all three species at these doses, the intraspecies metabolic profiles obtained were qualitatively similar. Thus, the respective amino acid conjugates (M310I010 in gerbil and sheep; PBAtau in mouse) were the major urinary metabolites detected. The sheep and gerbil exhibited little quantitative variation in metabolism with dose; in the sheep M310I010 accounted for 72, 73, 86, and 77% of the administered dose eliminated in 24 h at 0.1, 1, 10, and 100 mg/kg bw, respectively, and in the gerbil corresponding values were 22, 17, 20, and 21%. In the mouse, the taurine conjugate was 20, 21, and 25% of the dose at 0.1, 1, and 10 mg/kg bw, respectively, whereas at 100 mg/kg bw 30% were observed. Of the other reactions detected, glucuronide acid conjugation in the gerbil appeared to decrease as the dose was increased. There was a concomitant increase in unconjugated M310I011: 7.6, 9.1, 25, and 12% of the dose at 0.1, 1, 10, and 100 mg/kg bw, respectively. This possible saturation of the glucuronide pathway may also be seen to small extent in the mouse (26, 27, 17, and 22%), with a concomitant increase in free M310I011 (2.1, 2.1, 5.0, 8.3%). (M310I014, 4´-$HOSO_2$PBA and the unidentified metabolite VIII were present at minor products of M310I011 in the gerbil and mouse at 0.1, 1, and 100 mg/kg bw, as at 10 mg/kg bw. Variations in dose did not appear to appreciably affect the extent of hydroxylation of M310I011 in sheep, gerbil, or mouse.

Table 5.8.1-29: Hydroxylation of M310I011 (10 mg/kg bw) in various species

Species	Major urinary conjugate type	M310I025 4´-HO-PBA	Glucuronic acid conjugates of 4´-HO-PBA	M310I014 4´-$HOSO_2O$-PBA	Total hydroxylation
Rat	Sulfate	2.1	2.8	43.7	48.6
Hamster	Glucuronide	16.0	13.2	5.5	34.7
Marmorset		2.6, 1.7	21.6, 18.4	2.7, 2.7	26.9, 22.8
Rabbit		5.3	11.0	1.9	18.2
Guinea pig		1.0	13.9	3.0	17.9
Mouse	Taurine	2.0	1.1	5.2	8.3
Mallard duck[a]	Glycylvaline	0.8	0.7	2.6	4.1
Sheep	Glycine	6.8, 6.8	/	/	6.8, 6.8
Gerbil		1.0	1.5	1.2	3.7
Ferret[b]		0.8	/	2.7	3.5
Cat		/	/	/	/

6. The effect of route of administration on the metabolism of M310I011 in mouse and sheep

As with the dose-level studies, the metabolic profile of sheep urine remained very similar when M310I011 (10 mg/kg bw) was administered to these animals either by ip or po routes. In each case, M310I010 was the major metabolite (88% and 90% ip and po, respectively) with similar minor amounts of M310I025 (4´-HO-PBA) and unchanged M310I011 being detected. In the mouse, however, at 10 mg/kg bw hydroxylation appeared more extensive after po dosing than ip injection. Amounts of urinary M310I025 increased from 2% (ip) to 13.2% (po) of the dose; amounts of free M310I011 eliminated are also increased 4-fold. PBAtau, however, remains the principal urinary metabolite detected after administration by both routes. It is noteworthy that the radioactivity eliminated in the urine following po dosing was 88%, but was 67% afer ip injection.

7. Discussion

M310I011 is rapidly absorbed and in the majority of cases it undergoes extensive metabolism and is excreted predominantly via the urine; faecal elimination is a minor excretory pathway in most species. The major metabolic reactions include direct conjugation of the carboxyl group with amino acids (glycine in sheep, gerbil, cat, and ferret; taurine in mouse and ferret, a dipeptide, glycylvaline, in the mallard duck) or with glucuronic acid. Oxidation occurs extensively in the rat and, to lesser extents, in some other species. The phenolic compound produced (M310I025) is subsequently conjugated with sulfate or glucuronic acid. Thus, M310I014 forms the major metabolite in the rat, and the ether and ester glucuronides of 4´-HO-PBA (generally accompagnied by glucuronide of M310I011) are formed in the marmorset, hamster, guinea pig, and rabbit. Other hyhydroxylsomers are formed in some species, but are quantitatively, together with other unidentified metabolites, of minor significance. Variations in dose or route did not appreciably affect the pattern of metabolism of M310I011.

Benzoic acid shows very little interspecies variation. It was excreted rapidly in the urine mainly as hippuric acid, except in the ferret (benzoylglucuronide).

M310I025 is mainly metabolized by sulfation and glucuronidation, acting rather as a phenol than a carboxylic acid. Appreciable amounts of unchanged M310I025 are eliminated in the gerbil and mouse. Furthermore, M310I025 is eliminated more rapidly in the urine of both the gerbil and mouse than is M310I011.

III. CONCLUSION

In this study the species differences in metabolism of M310I011 were investigated. It has been shown that M310I011 is rapidly absorbed and in the majority of cases it undergoes extensive metabolism and is excreted predominantly via the urine. The major metabolic reactions include direct conjugation of the carboxyl group with amino acids or with glucuronic acid. Oxidation occurs extensively in the rat and, to lesser extents, in some other species.

Report: CA 5.8.1/40
[redacted] 2000a
CL 206128: Acute oral toxicity study in mice
AL-460-099

GLP: yes
(certified by Ministry of Agriculture, Forestry and Fisheries of Japan, Japan)

Executive Summary

Single doses of 1021, 1429, and 2000 mg/kg bw of M310I011 preparations in corn oil were given to groups of 5 male and 5 female animals each by gavage. Animals were observed for 14 days. No mortality occurred in the control and 1021 mg/kg bw dose groups. Each 1/5 males and 3/5 females were found dead in the 1429 and 2000 mg/kg bw dose groups, respectively. Accordingly, the oral LD_{50} was found to be greater than 2000 mg/kg bw for males and 1511 mg/kg bw for females, respectively:

Rat, oral: $LD_{50} > 2000$ mg/kg bw (males),
$LD_{50} = 1511$ mg/kg bw (females)

Clinical signs noted were prone position, lateral position, restlessness, stupor, sedation, decrease in or loss of spontaneous motor activity, convulsions, ptosis, and soiled fur in the external genital region in both males and females. The mean body weights of the administration groups increased throughout the study period. In the animals that died during the study red color and/or edema of the small intestine and red/black contents in the small intestine in both males and females and black spots in the glandular stomach and soiled fur in the external genital region in females were noted. No macroscopic pathologic abnormalities were noted in the animals examined at the end of the observation period.
Under the conditions of this study the median lethal dose of M310I011 after oral administration was found to be greater than 2000 mg/kg bw in males and 1511 mg/kg bw in females, respectively.

DocID (AL-460-099)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: CL 206128 (3-phenoxybenzoic acid)
Description: Powder/white
Lot/Batch #: AC11303-61
Purity/content: 99%

2. Vehicle: Corn oil

3. Test animals:

Species:	Mouse
Strain:	Crj:CD-1
Sex:	male/female
Age:	6 weeks (at administration of test substance)
Weight at dosing (mean):	25-30 g (males), 20-25 g (females)
Source:	Atsugi Breeding Center, Charles River Japan Inc., Shimofurusawa, Atsugi-shi, Kanagawa, Japan
Acclimation period:	8 days
Diet:	Pellet diet MF (Oriental Yeast Co., Ltd., Azusawa, Itabashi-ku, Tokyo), ad libitum
Water:	Well water, sand and charcoal filtered, sterilited with sodium hypochlorite, ad libitum
Housing:	Five animals per aluminium cage with wire-mesh floor (Tokiwa Kagakukikai Co., Ltd., Ueno, Taito-ku, Tokyo)
Environmental conditions:	
Temperature:	24 °C
Humidity:	55%
Air changes:	at least 10 times per hour
Photo period:	Alternating 12-hour light and dark cycles, artificial light from 7 am to 7 pm

B. STUDY DESIGN AND METHODS

1. Dates of work: 13-Oct-1999 - 27-Oct-1999 (Experimental period)

2. Animal assignment and treatment:

Single doses of 1021, 1429, and 2000 mg/kg bw of M310I011 preparations in corn oil were given to groups of 5 male and 5 female animals each by gavage, which were fasted for 2-3 hours before and 3 hours after administration. Clinical signs and symptoms were recorded 30 min, 1, 3, and 6 hours after administration and afterwards at least once daily for the individual animals up to 14 days post-administration. Individual body weights were determined shortly before administration, weekly thereafter and at the end of the study, or when the animal was found dead. The animals were sacrificed after ether anesthesia and subjected to necropsy including gross pathological examination on the last day of the observation period or as soon as possible after death in case of animals that died before.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality occurred in the control and 1021 mg/kg bw dose groups. Each 1/5 males and 3/5 females were found dead in the 1429 and 2000 mg/kg bw dose groups, respectively. Deaths occurred at 3 hours (males) and from 3 hours to 1 day (females) after administration.

B. CLINICAL OBSERVATIONS

Clinical signs noted were prone position, lateral position, restlessness, stupor, sedation, decrease in or loss of spontaneous motor activity, convulsions, ptosis, and soiled fur in the external genital region in both males and females. Additional findings included wetted fur in the external genital region in males and tremor, bradypnea, hypothermia, and lacrimation in females. These signs began to appear from 30 min after administration in both males and females and disappeared by day 5 and 2 in surviving males and females, respectively. No clinical signs were observed in the vehicle control animals.

C. BODY WEIGHT

The mean body weights of the administration groups increased throughout the study period.

D. NECROPSY

In the animals that died during the study red color and/or edema of the small intestine and red/black contents in the small intestine in both males and females and black spots in the glandular stomach and soiled fur in the external genital region in females were noted. No macroscopic abnormalities were observed in the surviving animals.

III. CONCLUSION

Under the conditions of this study, the oral LD_{50} for M310I011 in mice was determined to be greater than 2000 mg/kg bw for males and 1511 mg/kg bw for females.

Report: CA 5.8.1/41
[redacted] 1979a
A neurotoxicity study on the pyrethroid metabolite 3-Phenoxybenzoic acid (3-PBA)
CY-470-007
Guidelines: none
GLP: no

Executive Summary

M310I011 (Batch: 19027-6; Purity: 99%) was administered orally by gavage to groups of 8 male and 8 female rats at concentrations of 0, 25, 77 and 375 mg/kg bw/day over a period of 7 days. The positive control substance Cypermethrin was applied at 150 mg/kg bw/day. No clinical signs of intoxication were seen in any of the three groups dosed with M310I011, although mortality did occur with one female death in each dose group and one male death in the high dose group. Slight weight loss was observed in the high dose group during the dosing period. Normal weight gain was observed in all groups after cessation of dosing.
No increase in beta-glucuronidase and beta-galactosidase activities were observed in either the distal or proximal sections of the sciatic/posterior tibial nerve or in the trigeminal ganglia of the groups of rats dosed with M310I011. Groups treated with 25 mg/kg bw showed a statistically significant lower beta-galactosidase activity in the trigeminal ganglia. This decrease in activity however was marginal and was only seen in the females. Moreover this decrease was not seen in any of the rats given higher doses of M310I011.
Rats treated with cypermethrin showed a significant increase in beta-glucuronidase and beta-galactosidase activities. These enzyme increases were largest and most reproducible in the distal section of the sciatic/posterior tibial nerve and in the trigeminal ganglia.
Therefore, under the conditions of the present study the metabolite M310I011 is unlikely to be responsible for the enzymatic changes seen in the sciatic/posterior tibial nerve with cypermethrin.
(Doc ID CY-470-007)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: 3-Phenoxybenzoic acid
Description: not available
Lot/Batch #: 19027-6
Purity: 99%
Stability of test compound: The test substance was stable if kept cool and in the dark.

2. Vehicle and/or positive control: DMSO and Cypermethrin (WL 43467)

3. Test animals:

Species:	Rat
Strain:	Wistar
Sex:	Male and female
Age:	10-12 weeks
Weight at day 1 after dosing:	♂: approximately 93 – 101 g ♀: approximately 96 – 101 g
Source:	Shell Toxicology Laboratory (Tunstall), Sittingbourne, UK
Acclimation period:	no data
Diet:	no data
Water:	no data
Housing:	Single housing
Environmental conditions:	
Temperature:	18 - 24 °C
Humidity:	no data
Air changes:	no data
Photo period:	no data

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: September 1979

2. Animal assignment and treatment:

M310I011 was administered orally by gavage to groups of 8 male and 8 female rats at concentrations of 0, 25 (low dose), 77 (mid dose) and 375 mg/kg bw/day (high dose) over a period of 7 days.

3. Test substance preparation:

M310I011 was applied as a 10% (w/v) solution in DMSO.

4. Statistics:

Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed but no further details were given.

C. METHODS

1. Observations:
A check for moribund and dead animals as well as for clinical signs of toxicity was made before the start of the administration period and at frequent intervals after dosing.

2. Body weight:
Body weight was determined before the start of the administration period and at frequent intervals after dosing.

3. Enzyme determination:
Three weeks after the commencement of dosing the rats were killed by cervical dislocation. The right and left sciatic nerves were dissected as far as the distal phalangeal branche of the posterior tibial nerve. Each dissected sciatic/posterior tibial nerve was then dissected into a “proximal” and “distal” half. The right and left trigeminal ganglia were dissected free after removal of the brain.
Each tissue sample was weighed and homogenized in a volume of ice-cold 0.1 M acetate buffer (pH 4.5; containing 0.1% v/v Triton X-100) calculated to yield a 1% w/v homogenate.
Beta-galactosidase activity was determined using methylumbelliferyl-galactoside as substrate in the enzyme assay using fluorescence measurement for quantitation.
Similarly beta-glucuronidase activity was determined using methylumbelliferyl-glucuronide as substrate.

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSES
No details given

B. OBSERVATIONS

1. Clinical signs of toxicity
No clinical signs were observed throughout the study after treatment with M310I011.
After treatment with Cypermethrin ataxia, abnormal gait, hyperexcitability, and tremor were observed.

2. Mortality
In every group dosed with M310I011 one female rat was found dead. One male rat of the high dose group was found dead. Mortalities occurred between day 2 and day 5.
After treatment with Cypermethrin 2 females were found dead. Mortalities occurred between day 2 and day 8.

C. BODY WEIGHT AND BODY WEIGHT GAIN

No weight gain was observed in any dose group including the control group during the dosing period. After dosing rats of all groups gained weight normally. During dosing weight loss was observed in the 375 mg/kg bw group and in the females of the 77 mg/kg bw group.

D. ENZYME ACTIVITY

No increase in beta-glucuronidase and beta-galactosidase activities were observed in either the distal or proximal sections of the sciatic/posterior tibial nerve or in the trigeminal ganglia of the groups of rats dosed with M310I011. Groups treated with 25 mg/kg bw showed a statistically significant lower beta-galactosidase activity in the trigeminal ganglia. This decrease in activity, however was marginal and was only seen in the females. Moreover this decrease was not seen in any of the rats given higher doses of M310I011.
Rats treated with Cypermethrin showed a significant increase in beta-glucuronidase and beta-galactosidase activities. These enzyme increases were largest and most reproducible in the distal section of the sciatic/posterior tibial nerve and in the trigeminal ganglia.

III. CONCLUSIONS

The administration of Cyphermethrin produces the expected neurochemical changes in the rat peripheral nervous system. The metabolite M310I011 did not induce the biochemical changes that were observed with Cypermethrin, and is therefore unlikely responsible for the neurotoxic properties.

Supplemental information from open literature about toxicokinetics of pyrethroid metabolits in males and female rats was evaluated in the DAR or lambda-cyhalothrin [see Ueyama et al., 2010; discussed in Draft Renewal Assessement Report of Lambda-cyhalothrin or RMS Sweden of February 2013, page 125-129] indicating that elimination and distribution of M310I011 shows no gender-related differences in rats.

Information from the open literature about the endocrine investigations with M310I011 (PBAcid) is summarized in the Table 5.8.1-30 below. The Literature is however described in more detail in the chapter CA 5.8.3.

In vitro studies on endocrine activity:
M310I011 has been reported to show some weak estrogenic effects on mRNA expression level for estrogen receptor and pS2 at approx. 1000-fold higher concentrations than beta-E2 (Jin et al., 2010; [see CA 5.8.3/17 2010/1232199]). However, an activation of an estrogen receptor-dependent gene-expression was consistently not seen in several transactivation assays, but weak anti-estrogenic potential was repeatedly demonstrated in yeast and mammalian systems. While the RIC20 was found in the nanomolar range, a significant inhibition was only seen in the µ-molar concentration range that is not considered relevant for the invivo situation (IC_{50} of 10-100 µM). E-Screen assays in MCF-7 cells showed also very weak estrogen like effect by M310I011 by inducing proliferation at 0.1 µM about 1.3-fold above control, but this was not reproduced by Laffin et al., 2010, [see CA 5.8.3/16 2010/1232196]. An induction of proliferation of MCF-7 cells is not directly attributable to an estrogenic effect but might mirror other stimulis and therefore this study is not considered relevant but rather supportive.
M310I011 was consistently not active as androgen receptor agonist in yeast and in mammalian cells. An anti-androgenic potential was not seen in yeast cells and in mammalian cells the transactivation of human androgen receptor via DHT was reduced about 20% at 1.21 mM. Therefore this finding is rather considered unrelevant for further consideration.
No acitivty was seen of M310I011 on the thyroid receptor dependent genexpression. Some anti-TH activity is calculated with an RIC20 in the µ-molar range (4.76E-06M) but the complete measure did not show any significant inhibition up to 10 µM. As studies with cypermethrins in general did not reveal any thyroid toxicity, this weak potency found for one of the main metabolites is not considered of importance as it is not reflected in any in vivo study.

In vivo studies:
Laffin et al., 2010 [see CA 5.8.3/16 2010/1232196] evaluated the estrogenic activity in vivo using the uterotrophic assay in Sprague-Dawley rats. Ovariectomized animals were orally gavaged at 1, 5, and 10 mg/kg bw of M310I011 dissolved in corn oil.once daily for 3 days. No effect on uterine wet weigth or body weight was found. In addition no effect on organ weights, onset of puberty and sexual maturation was found in a pubertal assay in Sprague-Dawley rats at 0, 1, 5 or 10 mg/kg bw/day administered from weaning (PND 22) until detection of the onset of puberty by vaginal opening.

Considering all available data on endocrine potential, M310I011 is not considered to be estrogenic, anti-estrogenic, androgenic or anti-androgenic active at concentrations relevant for the in vivo situation. A significant effect on the thyroid receptor was not seen, and the slight antagonistic trend on the thyroidreceptor at around 10 µM is not considered a relevant concentration range in the invivo situation and in addition it is not reflected by the toxicity profile of the active ingredient alpha-cypermethrin.

Toxicological evaluation of M310I011

The QSAR evaluation of M310I011 is of good reliability and by weight of evidence there was no alert for genotoxicity.

In an Ames-test conducted [see CA 5.8.1/36 AL-435-010] M310I011 was not genotoxic without or with metabolic activation. An in vitro chromosome aberration test in P53 deficient V79 cells [see CA 5.8.1/37 2014/1168736] showed a positive response without metabolic activtion but without a clear dose-response relationship. With metabolic activation the isolated finding in the mid dose group was not reproduced by the repeat experiment and was furthermore without dose-response relationship and thus not considered indicative of a positive genotoxic response. The subsequently conducted in vivo Micronucleus test was negative [see CA 5.8.1/38 2015/1001101]. In conclusion M310I011 was not considered to be genotoxic by weight of evidence

The available systemic toxicity studies indicate a moderate short-term toxicity and give no indication that M310I011 is responsible for the neurotoxic properties known for cypermethrins. The acute toxicity is mice is low with an LD_{50} greater than 2000 mg/kg bw for males and 1511 mg/kg bw for females. Information in rat is derived from the 7-day neurotoxicity mode of action study and from the apical endocrine studies in female rats, while the neurotoxicity study indicates some toxicity down to the lowest tested dose of 25 mg/kg bw/day in particular females but without a dose response, the 3-day gavage administration in the uterotrophic assay did not give any evidence for systemic toxicity up to the highest dose tested i.e. 10 mg/kg bw/day. With regard to the pubertal assay there was also no indication for systemic toxicity up to the highest tested dose of 10 mg/kg bw/day when applied from weaning (PND up to the onset of puberty).

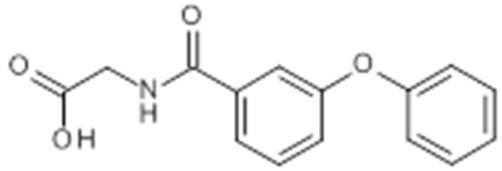
Literature data indicate that M310I011 has no relevant endocrine activity on the estrogenic, androgenic or thyroid system.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I011 is by weight of evidence considered to be not genotoxic. The available toxicological database does not provide any concern for M310I011. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the relevant TTC-threshold. In conclusion M310I011 is considered to be **not toxicologically relevant**.

M310I010 (other denominators: Reg. No. 4108084, 3PBA glycine, WL 46194, CL 117585, N-(3-phenoxybenzoyl)glycine)

M310I010 is the glycine conjugate of M310I011. It is determined as a rat, livestock (goat) and crop (wheat) metabolite.



a. Toxicological evaluation of M310I010

Being the glycin-conjugate of M310I011, toxicological evalution of M310I010 is based on the unconjugated analogon. Conjugation of metabolites with amino acids are according to the EFSA Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment [EFSA Journal 2012;10(07):2799] considered to probably not cause higher toxicity of the metabolites. Moreover it has been shown in several mammalian species that M310I010 is the major metabolite of M310I011 and thus it can be considered to be intrinsically tested in the studies conducted with M310I011.

For the non-conjugated structural analogue M310I011 results from an Ames test an Micronucleus test in vitro and a Micronucleus test in vivo are available [see CA 5.8.1/36 AL-435-010], [see CA 5.8.1/37 2014/1168736] and [see CA 5.8.1/38 2015/1001101]. In the Ames-test M310I011 was not genotoxic without or with metabolic activation. The in vitro chromosome aberration test in P53 deficient V79 cells [see CA 5.8.1/37 2014/1168736] showed a positive response without metabolic activtion but without a clear dose-response relationship. With metabolic activation the isolated finding in the mid dose group was not reproduced by the repeat experiment and was furthermor without dose-response relationship and thus not considered indicative of a positive genotoxic response. The subsequently conducted in vivo Micronucleus test showed negative results [see CA 5.8.1/38 2015/1001101]. In conclusion the glycin-conjugate M310I010 is not considered to be genotoxic by weight of evidence based on the studies conducted with M310I011. The available systemic toxicity studies for M310I011 indicate a moderate acute toxicity and give no indication that M310I011 respectively its analogon M310I010 are responsible for the neurochemical changes known for cypermethrins. Therefore, based on the negative in vitro data regarding mutagenicity and clastogenicity of the structural analogue M310I011, the glycin-conjugate M310I010 is considered to be not genotoxic.

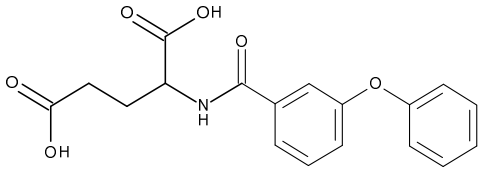
The available systemic toxicity studies for M310I011 indicate a moderate acute toxicity and give no indication that M310I011 respectively its analogon M310I010 are responsible for the neurochemical changes known for cypermethrins.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I010 based on the information available for M310I011 is by weight of evidence considered to be not genotoxic. The available toxicological database does not provide any concern for M310I010. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the relevant TTC-threshold. In conclusion, M310I010 is considered to be **not toxicologically relevant**.

M310I026 (other denominators: Reg. No. 4110960, 3-phenoxy-benzoyl glutamic acid)

M310I026 is the glutamate conjugate of M310I011. It is determined as a crop (wheat) metabolite.



a. Toxicological evaluation of M310I026

Being the glutamate-conjugate of M310I011, toxicological evalution of M310I026 is based on the unconjugated analogon. Conjugation of metabolites with amino acids are according to the EFSA Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment [EFSA Journal 2012;10(07):2799] considered to probably not cause higher toxicity of the metabolites.

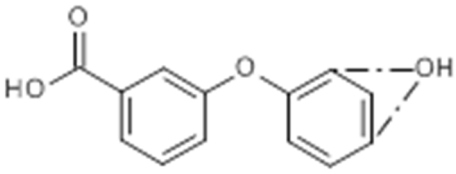
For the non-conjugated structural analogue M310I011 results from an Ames test an Micronucleus test in vitro and a Micronucleus test in vivo are available [see CA 5.8.1/36 AL-435-010], [see CA 5.8.1/37 2014/1168736] and [see CA 5.8.1/38 2015/1001101]. In the Ames-test M310I011 was not genotoxic without or with metabolic activation. The in vitro chromosome aberration test in P53 deficient V79 cells [see CA 5.8.1/37 2014/1168736] showed a positive response without metabolic activtion but without a clear dose-response relationship. With metabolic activation the isolated finding in the mid dose group was not reproduced by the repeat experiment and was furthermor without dose-response relationship and thus not considered indicative of a positive genotoxic response. The subsequently conducted in vivo Micronucleus test showed negative results [see CA 5.8.1/38 2015/1001101]. In conclusion the glutamate-conjugate M310I026 is not considered to be genotoxic by weight of evidence based on the studies conducted with M310I011.

The available systemic toxicity studies for M310I011 indicate a moderate acute toxicity and give no indication that M310I011 respectively its analogon M310I026 are responsible for the neurochemical changes known for cypermethrins.

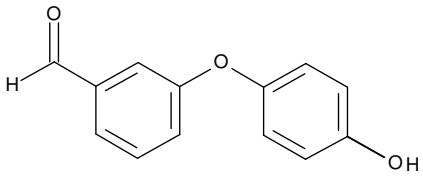
With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

M310I026 based on the information available for M310I011 is by weight of evidence considered to be not genotoxic. The available toxicological database does not provide any concern for M310I026. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the relevant TTC-threshold. In conclusion, M310I026 is considered to be **not toxicologically relevant**.

M310I013 (other denominators: CL 213336, WL 46114) and M310I025 (other denominators: Reg.Nr.4110493)



M310I013



M310I025

M310I013 is a metabolite found in rat. M310I025 is the para-hydroxylated derivative and is a metabolite identified in wheat and cabbage. Given the experimental methods available at study conduct of the cabbage and the wheat study the actual position of the hydroxylation group could not be specified. However, taking together the knowledge on metabolic pathways in crops (wheat, cabbage) and live-stock animals and mammalian species [see structure of M310I017 No. 2 above, and the extensive data on metabolism of M310I011 in mammalian species No. 16 above] it is likely that the actual position of the hydroxylation group is the para-position and thus M310I013 as determined in rat is identical to M310I025 as determined in wheat and cabbage.

a. QSAR Predicitions on M310I013 and M310I025

OASIS TIMES (V.2.27.15.146; Mutagenicity S-9 activated v09.09) [see molecule 12 of reports [see KCA 5.8.1/1 2014/1289314] and [see KCA 5.8.1/2 2014/1289315]]
There were **no** Ames mutagenicity alerts for M310I013 or in-silico generated metabolites and no structural alerts were reported. The same holds true for in-vitro chromosome aberration. In all cases the structures were out of domain.

VEGA: Mutagenicity model (CAESAR, version 2.1.9) [see molecule 12 of report [see KCA 5.8.1/5 2014/1289317]]
M310I013 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Two of the six most similar molecules had positive experimental data. The other four metabolites were predicted 'non-mutagen', which was experimentally confirmed. The concordance of the total underlying database was moderate (0.668) and thus is not very robust. Both the positive (similarity 0.844 to 0.854) and the negative molecules (similarity 0.846 to 0.861) have a reasonably similar structure to M310I013. Therefore, the chemical space does adequately cover the structure of M310I013.

VEGA: Mutagenicity model (SarPy; version 1.0.6-DEV) [see molecule 12 of report [see KCA 5.8.1/5 2014/1289317]]

M310I013 could be out of model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. The same metabolites as reported in the CAESAR model were also used in the SarPy model.

VEGA: Mutagenicity model (TOXTREE; version 1.0.0-DEV) [see molecule 12 of report [see KCA 5.8.1/5 2014/1289317]]
M310I013 could be out of the model applicability domain. The prediction is **'non-mutagen'** with no specific structural alerts. Two of the six most similar molecules had positive experimental data. The concordance of the total underlying database was low (0.496) and thus is not very robust. All six molecules (similarity 0.798 to 0.821) have a reasonably similar structure to M310I013. Therefore, the chemical space does adequately cover the structure of M310I013.

Conclusion on QSAR evaluations
No conclusive structural alert was identified for M310I013/M310I025.

b. Toxicological data on M310I013 and its structural analog M310I025

M310I013/M310I025 are reported in the literature to show neither estrogenic nor anti-androgenic activity.

Table 5.8.1-31: Endocrine activity studies with M310I013/M310I025

Endpoint	Test system with endpoint	Endocrine activity	Positive control	Reference Doc ID
In vitro data were identical for both metabolites				
ER-activation	hER transactivation in MCF-7 cells (Luciferase)	ER-agonist: not active ER-antagonist: Not tested	Agonist: E2 EC20: 2.4 E-8M	Tange et al., 2000 2000/1024078
AR-activation	hAR transactivation in CHO cells (Luciferase)	AR-agonist: not tested AR-antagonist: not active	Antagonist: Flutamide: IC_{20}: 0.16E-6 M IC_{50}: 0.62E-6M	

c. Toxicological evaluation of M310I013/M310I025

The available systemic toxicity studies for M310I011 indicate a moderate acute toxicity and give no indication that M310I011 respectively its analogon M310I013/M310I025 are responsible for the neurotoxic properties known for cypermethrins.

The QSAR evaluation of M310I025 the para-hydroylated moiety is of moderate reliability and by weight of evidence there was no conclusive alert for genotoxicity.
M310I013/M310I025 is the ring-hydroxylated analogon of M310I011. Hydroxylation of the ring system without any cleavage of the ring is often identified as probably not causing higher toxicity of metabolites (EFSA, 2012; 10(07):2799).

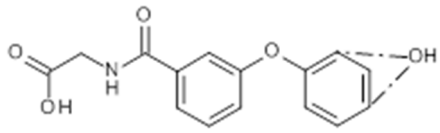
For the structural analogon M310I011 results from an Ames test an Micronucleus test in vitro and a Micronucleus test in vivo are available [see CA 5.8.1/36 AL-435-010], [see CA 5.8.1/37 2014/1168736] and [see CA 5.8.1/38 2015/1001101]. In the Ames-test M310I011 was not genotoxic without or with metabolic activation. The in vitro chromosome aberration test in P53 deficient V79 cells [see CA 5.8.1/37 2014/1168736] showed a positive response without metabolic activtion but without a clear dose-response relationship. With metabolic activation the isolated finding in the mid dose group was not reproduced by the repeat experiment and was furthermor without dose-response relationship and thus not considered indicative of a positive genotoxic response. The subsequently conducted in vivo Micronucleus test was negative [see CA 5.8.1/38 2015/1001101]. In conclusion the structural analogon M310I013/M310I025 was not considered to be genotoxic by weight of evidence based on the studies conducted with M310I011. Therefore, based on the negative in vivo data regarding mutagenicity and clastogenicity of the structural analogue M310I011 in combination with the negative prediction for M310I013 in the various QSAR models, M310I013 is considered to be not genotoxic.

M310I013/M310I025 showed no estrogenic or anti-androgenic properties. Further investigations are not considered relevant.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. However, the acute estimates of M310I025 will slightly exceed the TTC level of 5 µg/kg bw/day [see table section MCA 6.9]. However, the available data on M0310I011 indicate a moderate acute toxicity only [see section 5.8.1 No. 16 above]. The short-term NOAEL determined in the apical endocrine modulation studies was 10 mg/kg bw/day and thus by magnitude above the TTC-threshold without indicating any relevant toxicity.

M310I013/M310I025 based on the information available for M310I011 is by weight of evidence considered to be not genotoxic. The available toxicological database does not provide any concern for M310I025. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is slightly exceeding the relevant TTC-threshold but available toxicity data do not indicate a relevant concern for acute toxicity. In conclusion, M310I013/M310I025 are considered to be **not toxicologically relevant**.

M310I012



M310I012 is a metabolite found in rats and plants (wheat). M310I012 is the glycin-conjugate of M310I013/M310I025 respectively. As discsussed above taking together the knowledge on metabolic pathways in other crops (wheat) live-stock animals and mammalian species [see structure of M310I017 No. 2 above, and data on metabolism of M310I011 No. 16 above] it is likely that the actual position of the hydroxylation group is the para-position.

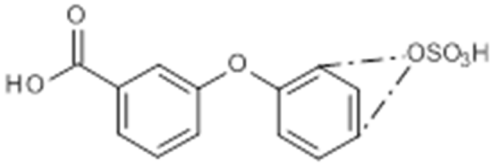
a. Toxicological evaluation of M310I012

Being a rat metabolite M310I012 is intrinsically covered by the toxicological testing of Alpha-cypermethrin. As a glycin-conjugate thereof toxicological evalution of M310I012 is based on the unconjugated analogon M310I013/M310I025. Conjugation of metabolites with amino acids are according to the EFSA Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment [EFSA Journal 2012;10(07):2799] considered to probably not cause higher toxicity of the metabolites.

With regard to chronic consumer exposure the TTC concept for a presumably neurotoxic, non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC-threshold of 0.3 µg/kg bw/day for a presumably neurotoxic, non-genotoxic Cramer-class 3 compound. The estimated acute exposure level is also below the TTC-threshold of 5 µg/kg bw/day.

Based on the information available for M310I011 M310I012 is by weight of evidence is considered to be not genotoxic. The available toxicological database does not provide any concern for M310I026. In addition M310I012 as a rat metabolite is intrinsically covered by the toxicologically testing of alpha-cypermethrin. The estimated chronic exposure is below the TTC-threshold for presumably neurotoxic, non-genotoxic compounds. The estimated acute exposure is also below the relevant TTC-threshold.. In conclusion, M310I012 is considered to be **not toxicologically relevant**.

M310I014



M310I014 is a metabolite found in the rat. M310I014 is the sulate-conjugate of M310I013.

a. Toxicological evaluation of M310I014

Being a rat metabolite M310I014 is intrinsically covered by the toxicological testing of Alpha-cypermethrin.

III. Toxicological evaluation of group D: Phenoxybenzyl alcohol, aldehyde and benzoic acid and conjugates, hydroxylated Phenoxybenzoic acid and conjugates

The group Members of this Group this group include several metabolites identified in mammals and thus also in the rat, namely M310I011 (phenoxybenzoic acid), M310I010 (glycine-conjugate therof), M310I013 (hydroxylated phenoxybenzoic acid), M310I014 (sulfate conjugate) and M310I012 (glycine-conjugate) thereof.

Toxicological data are available for M310I024 (3-phenoxy-benzyl-alcohol), M310I018 (3-phenoxy-benzaldehyd) and M310I011 (3-phenoxybenzoic acid). This database comprises genotoxicity data for all three metabolites considered by weight of evidence not to be genotoxic. The metabolism data reported for M310I011 in several mammalian species including rat and mouse indicate that the hydroxylation in the para-position of the the terminal phenoxyring is the major metabolic route in rats and thus the identified hydroxylation products M310H012, M310I013 and M310I027 are all assumed to follow this pathway (hydroxylation at the para-position) although the final structure could not be defined in all cases.
Moreover the acute toxicity studies available for M310I024 and M310I018 indicate group members to be less toxic than the parent molecule alpha-cypermethrin. A subchronic 90-day rat study conducted with the aldehyde M310I018 indicated the liver and kidney as a target organs characterized by an increased metabolic activity. A NOEL of 50 mg/kg bw/day was determined in this study. In a neurotoxicity study conducted with M310I011 in comparison to cypermethrin effects on the nerval system were investigated. M310I011 is unlikely to be responsible for the enzymatic changes seen in the sciatic/posterior tibial nerve with cypermethrin.
With regard to potential endocrine activity literature data are available on M310I011, M310I24, M310I018. Literature data indicate that M310I011 has no relevant endocrine activity on the estrogenic, androgenic or thyroid system. M310I024 has no relevant activity on the estrogenic or androgenic system. M310I013 and its related structure M310I027 showed no estrogenic or anti-androgenic properties.
Based on this datapackage of relevant group members and the relation to the mammalian metabolism of alpha-cypermethrin **the metabolites of the group D are by weight of evidence not considered to be genotoxic or neurotoxic, do not bear a relevant endocrine activity and are not considered to be toxicological relevant.**

3-Hydroxybenzoic acid

I. Definition of group E: 3-Hydroxybenzoic acid

The "group E" comprises of a single molecule M310I019 i.e. 3-hydroxybenzoic acid

M310I019 (3-Hydroxybenzoic acid)

Evaluation of group E members

M310I019 (other denominators: CAS-No. 99-06-9, EC-No. 202-726-5, m-Hydroxy benzoic acid, 3-Hydroxy benzoic acid, FL-no 08.132)
M310I019 is identified as a food flavor. As such it was evaluated by EFSA [EFSA Journal 2012; 10(12):2994]. M310I019 is reported to be a known metabolite in microbial metabolism. Some investigations on pharmacological and nutritional benefitial effects are reported for M310I019 as a metabolite.

a. Toxicological data on M310I019

The EPA ACToR data-warehouse [http://actor.epa.gov/actor/GenericChemical?casrn=99-06-9] reports based on the information of NLM TOXNET Toxicology an acute oral LD_{50} of 2000 mg/kg bw in mice [reference: Quarterly Journal of Pharmacy & Pharmacology. Vol. 19, Pg. 483, 1946]. For rats an LD_{50} of 3700 mg/kg is reported [reference: Bollettino Chimico Farmaceutico. Vol. 112, Pg. 53, 1973]. In the UMD list of Acute Toxins, Teratogens, Carcinogens or Mutagens it is reported that M310I019 meets the University of Maryland definition of a Teratogen for the purpose of the Chemical Hygiene Plan as it was listed as a teratogen in the "Dangerous Properties of Industrial Materials", 7th Ed., by N. Irving Sax and Richard J. Lewis, however the underlying data could not be identified. There is some additional limited evidence published that M310I019 is not teratogenic [see CA 5.8.1/42 1972/1000521 below].

M310I019 was evaluated by EFSA as a food flavour [EFSA Journal 2012; 10(12):2994]. The group evaluation 20 comprised benzyl alcohols, benzaldehydes, a related acetal, benzoic acids, and related esters from chemical groups 23 and 30. M310I019 was assigned to the subgroup 2 (hydroxy- and alkoxy-ringsubstituted benzyl derivatives). M310I019 was assigned to structural Cramer class I and a threshold of concern (based on the TTC concept) of 1800 µg/person/day i.e. 30 µg/kg bw/day was derived. With regard to M310I019 no specific toxicological data are reported instead M310I019 was evaluated based on the grouping approach. Toxicological evaluation by EFSA based on grouping approach: By weight of evidence no safety concern with respect to genotoxicity was identified. Acute toxicity, repeated dose toxicity data and developmental / reproductive toxicity data of group candidate and supporting substances were consistent with the group evaluation and with the conclusion based on the TTC concept.

Some on pharmacological and nutritional benefitial effects are reported for M310I019 as a metabolite.

Report: CA 5.8.1/42
[redacted] 1972b
Biochemical mechanisms of salicylate teratology in the rat
1972/1000521
Guidelines: none
GLP: no

In this non-guideline prenatal toxicity study with limited exposure and limited parameters investigated M310I019 (m-Hydroxybenzoic acid) was investigated in comparison to salicylates and their other presumed derivatives. Groups of adult female Spreague-Dawley rats, aged 100 days at weaning, weighing 190 – 220 g were used. The animals were fed with Purina laboratory chow and water ad libitum. They were paired overnight with male rats of the same strain. 10 female animals were treated subcutaneously with m-Hydroxybenzoic acid at a dose equivalent to 380 mg/kg acetyl-salicylic acid on day 9 of gestation. The concurrent control of 15 female rats was treated with the vehicle i.e. deionized water. The source and purity of the administered compounds is not reported in the publication but indicated to be referenced in the underlying author's dissertation. The dose was administered in two equal portions with 2 hour interval. Animals were housed until day 20 of gestation, when they were sacrificed and the fetuses were removed. Uterus was inspected for resorptions and fetal death and external congenital malformations were reported. The mean fetus weight, the number of alive fetuses and the number and percentage of resorptions were in the same range as the control [see Table 5.8.1-32 below]. In contrast to the in parallel investigated acetyl-salicylic acid and salicylic acid no external malformations were reported for the fetuses from dams treated with M310I019.

Table 5.8.1-32: Results of non-guideline teratogenicity study with M310I019

Treatment group	No of dams	Dam mortality	Implan-tations	Mean fetus weight	No. of fetuses (alive)	Resorptions		Malformed fetus	
			Total No.	(g)	Total No.	Total No.	% of total implan-tations	Total No.	% of total living fetuses
Control	15	0	172	3.89 ± 0.44	169	3	1.7	0	0
Acetyl-Salicylic acid	10	0	114	**3.02 ± 0.70****	**93**	**21**	**18.4**	0	0
Salicylic acid	17	**1**	178	**3.09 ± 0.93****	**95**	**83**	**46.6**	0	0
M310I019	10	0	123	3.96 ± 0.43	120	3	2.4	0	0

** significantly different from control $p < 0.01$
Bold figures indicate treatment related changes

The study is considered to be of limited value due to significant differences from guideline teratogenicity studies. In particular the duration of exposure is insufficient and the parameters investigated are limited.

Classification of study: supplemental information

Information with regard to the endocrine potential of M310I019 was found in the open literature. A summary table of the available literature is provided in Table 5.8.1-33 below. The literature is however described in more detail in the chapter CA 5.8.3.

In vitro studies:

Considering all available data on endocrine potential and on aromatase inhibition, M310I019 is considered to display neither estrogenic activity in vitro nor inhibitory effects on aromatase activity in vitro.

Table 5.8.1-33: Endocrine activity studies with M310I019

Endpoint	Test system with endpoint	Endocrine activity	Positive control	Reference Doc ID
In vitro assays				
E-screen	MCF-7 cells (proliferation)	ER-agonist: Not active ER-antagonist: Not determined	Agonist: E2: EC50: 12E-3 M Antagonist:4HO-TAM: IC_{50}: 2.8±0.7E-6 M	van Meeuwen et al., 2008 2008/1102356
Aromatase inhibition	in vitro microsomal conversion of 1-β-^{3}H-androstenedion	Aromatase inhibition: Not active	4-OH-androstendion IC_{100}: 1E-6 M	van Meeuwen et al., 2008 2008/1102356

b. Toxicological evaluation of M310I019

M310I019 was evaluated by EFSA in the context of food-flavour ingredients [see Scientific Opinion on flavouring group evaluation, Revision 4: Benzylalcohols, benzaldehydes, a related acetal, benzoic acids, and related esters from chemical groups 23 and 30, EFSA Panel on Food Contact Materials, Enzymes, Flavourings and Processing Aids (CEF); http://www.efsa.europa.eu/de/efsajournal/doc/2994.pdf]. Evaluated as a Cramer-class 1 compound a threshold fo concern of 1800 µg/person/day was defined for the so-called FL-no. 08.132 based on a grouping approach. The available toxicological information for M310I019 gives no indication of a toxicological concern.

With regard to consumer exposure the TTC concept for a non-genotoxic compound was applied. The estimated exposure levels - back-calculated from worst-case exposure levels of alpha-cypermethrin for operators and consumers based on 100 % utilization of the reference value 0.02 mg/kg bw – would be below the TTC for a of 0.3 µg/kg bw/day for a presumably neurotoxic , non-genotoxic Cramer-class 3 compound and thus of course below the much higher threshold defined by EFSA for M310I019 being a Cramer-class 1 compound evaluated as a food flavor.
In conclusion M310I019 is considered to be **not toxicologically relevant**.

Toxicological evaluation of group E: 3-Hydroxybenzoic acid

Based on the grouping approach evaluated by EFSA as a food flavour **3-hydroxybenzoic acid is by weight of evidence not considered to be genotoxic or neurotoxic, does not bear a relevant endocrine activity and is not considered to be more toxic than the parent molecule.**

CA 5.8.2 Supplementary studies on the active substance or related substances

Studies evaluated in the draft monograph of the Rapporteur Member State Belgium September 1999: A mechanistic neurotoxicity study with oral administration in rats was presented in the first DAR as supplementary study but was used in the list of Endpoints under point Neurotoxicity/Delayed neurotoxicity and is therefore shifted into chapter CA 5.7. Furthermore literature data were discussed within the ECCO Peer review meeting - Full Report on alpha-cypermethrin [see KCA 5.8.2/1 AL-901-031] to conclude that no further studies on developmental neurotoxicity are necessary. These data are also shifted for a better understanding into chapter CA 5.7, too.

The endpoint "Other toxicological studies" during the last Annex I listing of Alpha-Cypermethrin was therefore as follows:

Other toxicological studies	No data- not required

Studies submitted in this AIR 3 dossier (Part I: peer-reviewed studies from other DARs):
In the DAR (2008) of zeta-cypermetrhin two crucial studies are presented that demonstrate the continuous exposure of pups via milk. One study is focusing on placental and lactational transfer, the other one is focusing on lactational transfer of dietary administered zeta-cypermethrin. Based on the similarity of properties a lactational transfer is thereby proven for alpha-cypermethrin, too. Based on these data an estimation of pup exposure via milk is calculated in CA 5.7 in order to demonstrate that lactational exposure of pups is at a sufficient degree to be used in human risk assessment.

Table 5.8.2-1: Summary of already peer-reviewed supplementary studies

Study	Test substance information	Endpoints			Reference
		NOAEL (mg/kg bw/day)	LOAEL (mg/kg bw/day)	Effect	
Dietary placental and lactation transfer, rats, 50, 125, 300 ppm GD 6-20 or GD6-LD21	Zeta-cypermethrin: batch No. PL03-0427; 81.8%			Zeta-cypermethrin was detected in maternal and fetal plasma	Copied from DAR zeta-cypermethrin (2006) : see CA 5.8.2/5 Doc ID 2006/7013990 [redacted]2005 a
Dietary exposure from GD 6 to LD17, rats, 125, 375 ppm and transfer in milk	Zeta-cypermethrin: batch No. PL03-0427; 81.8%			Dietary administration permits transfer from food to milk	Copied from DAR zeta-cypermethrin (2006): see CA 5.8.2/5 Doc ID 2006/7013990 [redacted] 2004 and amended by the EFSA conclusion with regard to R64, which was considered not relevant

Studies submitted in this AIR 3 dossier (Part II: not peer-reviewed studies):
Upon request of US EPA, an immunotoxicity study in male rats was conducted investigating the primary T-cell dependent IgM antibody response as assessed by the anti-Sheep red blood cell (SRBC) IgM ELISA and additionally by weight changes of spleen and thymus. The respective study is listed in Table 5.8.2-2. The immunotoxicity study did not reveal a specific effect on the T-cell dependent immune response or on immune-system related organs. Additionally, a 14-day range finding study was performed to set the dose levels for the subsequent immunotoxicity studies. This study is not listed in Table 5.8.2-2as the results are not end-point relevant.

For submission in Japan a general pharmacology study has been conducted investigating the effect of alpha-cypermethrin on vital functions of animals of different species. The respective study is listed in Table 5.8.2-2. The study showed the typical acute toxicity via action on the CNS and the cardiovascular system at sublethal doses. Furthermore a study to investigate the potential use of methocarbamol, mephenesin, or halothane as antidots on acute toxicity in rats has been performed. These studies are not mandatory in the EU and are therefore only summarized roughly.

In addition, literature data were taken into account. However, these data are judged to represent supplemental information only and do not provide relevant endpoints for human riskassessment.

Table 5.8.2-2: Summary of newly submitted not peer reviewed supplementary studies

Study	Test substance information	Endpoints			Reference

BAS 310 I (Alpha-Cypermethrin) - Immunotoxicity study in male Wistar rats - Administration via the diet for 4 weeks
2010/1057357
Guidelines: EPA 870.7800
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

BAS 310 I (batch COD – 000595, purity 99.2%) was administered via the diet to male Wistar rats at dietary dose levels of 0, 50, 150 and 450 ppm, respective 0, 3.99, 11.83 and 34.34 mg/kg bw/day for 4 weeks. Cyclophosphamide monohydrate (4.5 mg/kg bw/day) was used as a positive control. SRBC IgM antibody titers were similar between control and BAS 310 I treated animals. No immunopathological findings as well as general systemic toxicity findings were observed after treatment of animals with BAS 310 I.
The administration of the positive control Cyclophosphamide monohydrate (4.5 mg/kg bw/d) led to effects indicative of immunotoxicity, i.e. reduced absolute and relative spleen and thymus weight. Furthermore, SRBC IgM antibody titers were significantly lower compared to the control group. In addition, an impaired body weight development was observed after treatment of animals with cyclophosphamide.

Based on the results of the study the NOAEL was identified at 450 ppm (34 mg/kg bw/day) for general toxicity as well as for immunotoxicity for BAS 310 I.

(DocID 2010/1057357)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: BAS 310 I
Description: solid, white
Lot/Batch #: COD – 000595
Purity: 99.2%
Stability of test compound: The test substance was stable over the study period (Expiry date 01.06.2013).

2. Positive control: Cyclophosphamide Monohydrate (CAS No.: 6055-19-2)
Description: solid, white
Lot/Batch #: 1362353
Purity: 100%
Stability of test compound: The test substance was stable over the study period (Expiry date 08.10.2010).

3. Test animals:

Species:	Rat
Strain:	Crl:WI (Han)
Sex:	Male
Age:	36 ± 1 days at delivery; 42 ± 1 at the beginning of the administration period
Weight at dosing:	168.64 – 171.01 g
Source:	Charles River, Sulzfeld, Germany
Acclimation period:	6 days
Diet:	Kliba maintenance diet rat/mouse Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
Water:	Tap water ad libitum
Housing:	Group housing (4 animals per cage) in H-Temp (PSU, TECNIPLAST, Hohenpeißenberg, Germany) cages; floor area about 2065 cm².
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	Fully air-conditioned rooms; 15 of air-changes per hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

The study was conducted at BASF SE, Experimental Toxicology and Ecology, 67056 Ludwigshafen, Germany.

1. In life dates: 09-Feb-2010 - 16-Mar-2010)
(Dates of experimental work:09-Feb-2010 to 07-Sep-2010)

2. Animal assignment and treatment:
BAS 310 I was administered to groups of 8 male rats at dietary concentrations of 0, 50, 150, and 450 ppm for 4 weeks via the diet. Cyclophosphamide monohydrate (4.5 mg/kg bw/d) was administered by gavage as a solution in drinking water.
All animals were immunized 6 days before blood sampling and necropsy using 0.5 ml sheep red blood cells ($4x10^8$ SRBC/ml) administered intraperitoneally. The animals were assigned to the treatment groups by means of a computer generated randomization lists based on body weights.

3. Test substance preparation and analysis:
Previous tests indicated that BAS 310 I was stable in the diet at room temperature for at least 30 days. The stability of Cyclophosphamide Monohydrate (positive control substance) in the vehicle (drinking water) over a period of 32 days (in the freezer) was proven before the start of the study

Homogeneity analyses were performed at all concentrations at the start of the study (see Table 5.8.2-3). Samples also served for concentration control. From a strict chemical viewpoint, a homogeneity assay was not necessary because the compound is completely soluble in water at the concentration being dosed.

Table 5.8.2-3: Analysis of diet preparations for homogeneity and test-item content

Dose level [ppm]	Sampling	Concentration [ppm] Mean ± SD	Relative standard deviation [%]	Mean / of nominal concentration
50 ppm	23.01.2011	50.2 ± 2.3	4.6	100.4
150 ppm	23.01.2011	159.1 ± 5.8	3.6	106.1
450 ppm	23.01.2011	433.7 ± 14.1	3.2	96.4

Relative standard deviations of the homogeneity samples in the range of 3.2 to 4.6% indicate the homogenous distribution of BAS 310 I in the diet preparations. The actual test-item concentrations were in the range of 96.4 to 106.1% of the nominal concentrations.
For Cyclophosphamide monohydrate the 98.4 % of the nominal concentration was achieved.

4. Statistics:
Means and standard deviations of each test group were calculated for several parameters. Further statistical analyses were performed according to following tables:

Statistics of clinical examinations

Parameter	Statistical test
Body weight, body weight gains (control and test substance treatment)	A comparison of each group with the control group was performed using DUNNETT's test (two-sided) for the hypothesis of equal means
Body weight, body weight gains (control and Cyclophosphamide monohydrate treatment)	A comparison of the dose group with the control group was performed using the t-test (two-sided) for the hypothesis of equal means

Statistics of clinical pathology

Parameter	Statistical test
Clinical pathology parameters	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pair-wise comparison of each dose group with the control group was performed using Wilcoxon-test (two-sided) for the equal medians

Statistics of pathology

Parameter	Statistical test
Organ weights	Non-parametric one-way analysis using KRUSKALWALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using the WILCOXON test for the hypothesis of equal medians

C. METHODS

1. Observations:
The animals were examined for evident signs of toxicity or mortality twice daily on working days and once daily on weekends and public holidays.

The clinical condition of the test animals were recorded individually.
Detailed clinical observations of all animals were performed in a standard arena prior to the administration period and weekly thereafter. The standard arena had a size of 50 x 37.5 cm with walls of 25 cm height. If applicable the findings were ranked according to the degree of severity. The following parameters were examined:

1. abnormal behavior during handling
2. fur
3. skin
4. posture
5. salivation
6. respiration
7. activity/arousal level
8. tremors
9. convulsions
10. abnormal movements
11. impairment of gait
12. lacrimation
13. palpebral closure
14. exophthalmus
15. feces (appearance/consistency)
16. urine
17. pupil size

2. Body weight:
The body weight of the animals was determined before the start of the administration period in order to randomize the animals, at the start of the exposure period and thereafter twice weekly. The difference between the body weight on the respective day of weighing and the body weight on day 0 was calculated as body weight change.

3. Food consumption, food efficiency and compound intake:
Group food consumption was determined weekly (as representative value over 1 day) for each cage. The average food consumption was used to estimate the mean food consumption in grams per animal and day.
Water consumption was observed daily by visual inspection of the water bottles for any overt changes in volume.

The mean daily intake of test substance (group means) was calculated based upon individual values for body weight and food consumption.

$$\text{Substance intake for day x} = \frac{FC_x \times C}{BW_x}$$

BW_x = body weight on study day x [g]; FC_x= mean daily food consumption on study day x [g]; C = concentration in the food on study day x [mg/day]

4. Immuntoxicological examinations:
Primary T-cell dependent antibody response (anti-SRBC IgM ELISA) was performed on two dilutions (1:64 and 1:128)

4. Sacrifice and pathology:
All animals were sacrificed by decapitation under isoflurane anesthesia. The exsanguinated animals were necropsied and assessed by gross pathology. The following organs were sampled, weighed and examined histopathologically:

Pathology:
The following organs were collected (column C), weighed (W) and examined histopathologically (H, ✓: all groups, #: control and top dose).

C	W	H		C	W	H		C	W	H

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

1. Clinical signs of toxicity

No test substance-related clinical signs were observed in all animals treated with BAS 310 I and in animals which received Cyclophosphamide monohydrate as positive control.

2. Mortality

No mortality was observed throughout the study.

B. BODY WEIGHT AND BODY WEIGHT GAIN

No significant changes were observed in all animals tested with BAS 310 I. During the administration period the body weight change of the test group 4 (positive control) was significantly lower from study day 7 to study day 28 (maximum of 13% less on study day 24) [see Figure 5.8.2-1:and Table 5.8.2-4:].

Figure 5.8.2-1: Body weight and body weight development of male rats administered BAS 310 I for 4 weeks

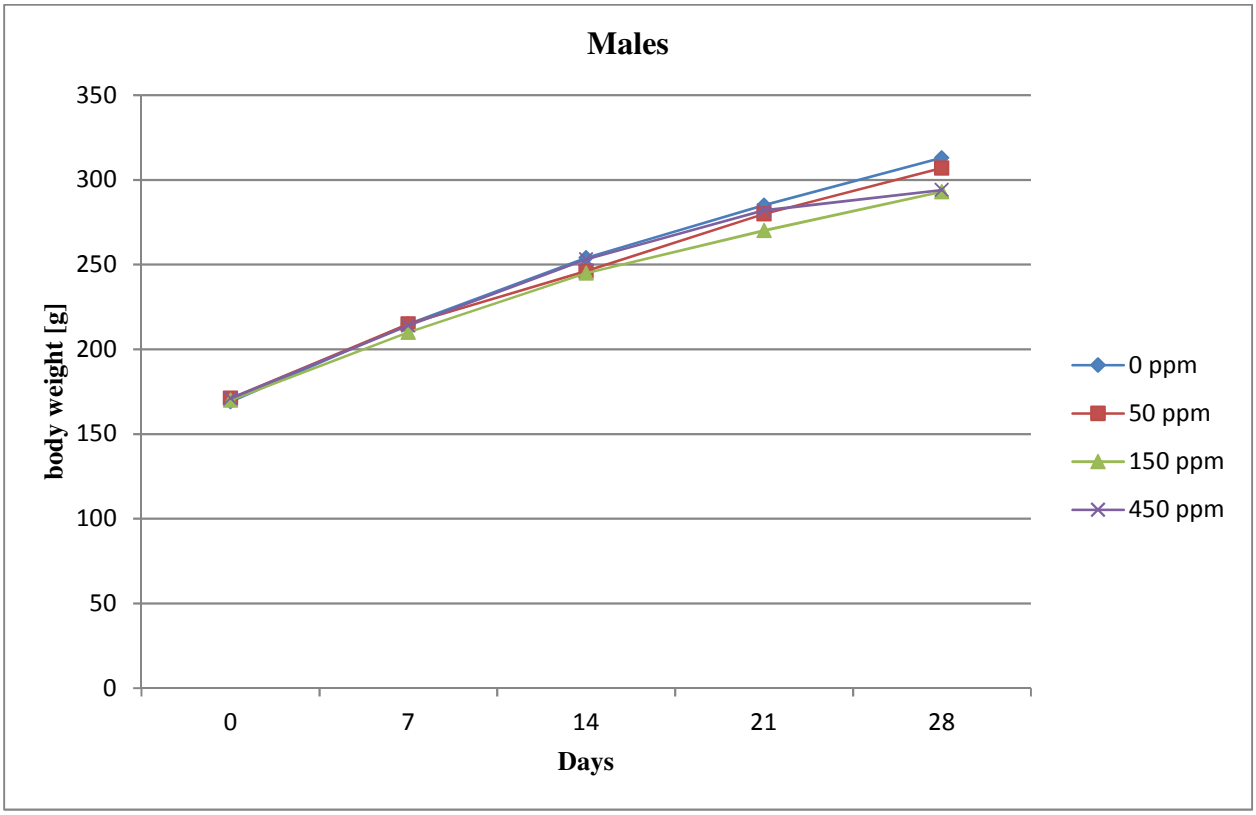

Table 5.8.2-4: Body weight and food consumption data of rats administered BAS 310 I for 4 weeks

	Males				
Dose level [ppm]	0	50	150	450	Positive control
Body weight [g]					
- Day 0	168.64	171.01	169.67	170.91	170.02
- Day 28	312.65	307.19	292.70	304.84	296.38
% (compared to control)		-.175	-6.38	-2.50	-5.21

% (compared to control)		-5.44	-14.57	-7.00	-12.26
Food consumption [g/day]					
- average week 1-4[§]	21.21	20.52	19.77	19.74	20.10
% (compared to control)		96.77	93.20	93.06	94.77

* $p \leq 0.05$ (Dunnett's test, two sided); [$] calculated from the weekly means

C. FOOD CONSUMPTION AND COMPOUND INTAKE

No effects on food consumption and food efficiency were observed.
The mean daily test substance intake was 3.99, 11.83, and 34.34 mg/kg bw/day at dietary dose levels of 50, 150 and 450 ppm, respectively.

D. BLOOD ANALYSIS

1. Primary T-cell dependent antibody response (anti-SRBC IgM ELISA)
Six days after immunization no difference between control and substance treated animals was observed. SRBC titers were significantly lower in animals treated with Cyclophosphamide monohydrate [see Table 5.8.2-5].

Table 5.8.2-5: Blood analysis findings of rats administered BAS 310 I for 4 weeks

Sex	Females								
Dose [ppm]	Values					% (compared to control)			
	0	50	150	450	Pos. control	50	150	450	Pos. control
SRBC [LU/l]	4.14	3.15	4.31	4.52	0.84*	76.09	104.10	109.18	20.29*

* $p \leq 0.05$ (Kruskal-Wallis and Wilcoxon-test, two sided)

E. NECROPSY

1. Organ weight

Terminal body weights (absolute and relative) were not significantly affected by treatment with BAS 310 I or Cyclophosphamide [see Table 5.8.2-6].

Mean absolute and relative weights of organs were comparable between control and BAS 310 I treated animals. Cyclophosphamide treated animals revealed a significant decrease of spleen and thymus weights.

Table 5.8.2-6: Terminal body and organ weights of rats administered BAS 310 I for 4 weeks

Sex	Females								
Dose [ppm]	Values					% (compared to control)			
	0	50	150	450	Pos. control	50	150	450	Pos. control
Terminal body weight [g]	289.7	284.8	269.9	285.1	274.8	98.31	93.17	98.41	94.86

rel. [%]	0.208	0.207	0.190	0.195	0.140**	99.52	91.79	102.63	71.79**
Thymus abs. [mg]	504.4	460.6	401.9	456.9	265.1**	91.32	87.26	113.68	58.02**
rel. [%]	0.174	0.162	0.147	0.158	0.096**	93.10	90.74	107.48	60.76**

** $p \leq 0.01$; Wilcoxon test, two sided

2. Gross and histopathology

No gross lesions were observed. In the absence of gross lesions no histopathological investigations were carried out.

III. CONCLUSIONS

Under the conditions of the study BAS 310 I did not reveal any signs of immunotoxicity when administered via the diet over a period of 4 weeks to male Wistar rats. The NOAEL for the immunotoxicologically relevant endpoints was set to 450 ppm (34 mg/kg bw/day), the highest dose tested. The oral administration of the positive control substance cyclophosphamide monohydrate (4.5 mg/kg bw/day) led to severe findings indicative of immunotoxicity. This was represented by significantly lower SRBC IgM antibody titres as well as reduced spleen and thymus weights. Thus, assay sensitivity was verified in the present immunotoxicity study performed in male Wistar rats.

Report: CA 5.8.2/3

Alphacypermethrin: General pharmacological study
AL-452-001
Guidelines: JMAFF 59 NohSan No 4200
GLP: yes
(certified by Ministry of Agriculture, Forestry and Fisheries of Japan, Japan)

Executive Summary

Alphacypermethrin (batch 351, purity 93.2%) was tested in a general pharmacological study in mice, rats, guinea pigs and rabbits. Clinical signs of toxicology, effects on the autonomic and central nervous system, effects on respiration and circulation, effects on digestive organs, effects on skeletal muscles and renal function were observed during the study.
Excitatory toxic signs typical for cyano pyrethroids were observed at 40 mg/kg or higher in mice and rats. Intravenous injection of the test substance to male rabbits at 12 mg/kg elicited cardiorespiratory changes and death. Oral administration at sub-lethal doses produced a decrease in transport activity in the small intestine in mice, and a decrease in body weight and temperature as well as an increase in urinary glucose. The present in vitro experiments revealed an increase in both muscle and nerve stimulated contraction of the diaphragm of rats and an increase in spontaneous motility of the ileum, and a decrease in agonist-induced contraction of the organ in the guinea pig. No distinct effects on hexobarbital sleeping time in male mice or on grip strength in male rats were observed.

(DocID 2000/7000975)

B. STUDY DESIGN AND METHODS

The study was conducted at the Institute of Environmental Toxicology, Ibaraki, Japan.

1. In life dates: 17-Aug-1999 - 27-Sep-1999)
(Dates of experimental work: 30-Aug-1999 to 16-Mar-2000)

2. Animal assignment and treatment:
Mice were treated with 2.6, 6.4, 16, 40, 100, and 250 mg/kg for assessment of general toxicity. For hexobarbital sleeping time measurements male mice were treated with 2.6, 6.4, 16, 40, and 100 mg/kg bw.
Transport activity of the small intestine in male mice was determined after treatment with 1.0, 2.6, 6.4, 16, 40, and 100 mg/kg.

Rats were treated with 16, 40, 100, 250, and 625 mg/kg test substance.
For assessment of cardiorespiratory parameters male rabbits were treated with 0.75, 3, and 12 mg/kg.
The solution containing the test substance was administered in a volume of 10 mL/kg to mice and rats, and 1 mL/kg to rabbits.

For assessment of agonist-induced contractions of the ileum in male guinea pigs the test substance was applied at concentrations of 0.1, 1, 10, and 100 µg/mL.

For assessment of electrical stimulation-induced contraction of diaphragm in male rats the test substance was applied at concentrations of 0.1, 1, 10, and 100 µg/mL.

In the in vitro experiments the maximum concentration emulsible in Krebs-Ringer solution containing Tween 80 was 100 µg/mL.

3. Test substance preparation:
Since the test substance is insoluble in water it was suspended in 1% Tween 80 aqueous solution for oral application to mice and rats. For intravenous injection to rabbits the test substance was dissolved in dimethylsulfoxide (DMSO, 15% final concentration) and then emulsified by mixing with physiological saline containing Tween 80 (5%). The suspension and emulsion were prepared immediately before each experiment.

4. Statistics:
The data were statistically analyzed by Dunnett´s or Steel´s multiple comparison test. Differences between groups were considered to be statistically significant at the $p \leq 0.05$ level.

C. METHODS

1. Effects on central nervous system:
Clinical signs of male and female mice were observed immediately before and 1 h, 3h, 6 h, 1 day, 2 days, 3 days, and 7 days after oral administration of the test substance (3 animals/dose).
Hexobarbital sleeping time in male mice was studied 1 h after oral administration (8 animals/dose). The hypnosis was induced by subcutaneous injection of hexobarbital (100 mg/kg) 1 h after the administration of the test substance. The time between disappearance and reappearance of righting reflex was measured.
Clinical signs of toxicity and body temperature in male rats were observed 1 day before and 1 h, 3h, 6 h, 1 day, 2 days, 3 days, and 7 days after oral administration of the test substance (5 animals/dose).

2. Effects on respiration and circulation
Cardiorespiratory function in male rabbits was evaluated after intravenous injection at cumulative doses of 0.75, 3, and 13 mg/kg every one hour (4 animals/dose). For assessment of respiratory function a thermistor type respiration sensor was fixed to a cannula inserted into a cut opening of the trachea. Relative change of respiratory pattern was recorded with 0.3 s of time constant. Blood pressure was measured using a polyethylene tubing, which was inserted into the femoral artery about 10 cm with the opposite of the tubing being connected to a high pressure transducer. Values of systolic, diastolic, and mean blood pressure were measured with a digital meter. The electrodes for recording the ECG were fixed on a right forelimb and right and left hindlimbs. Heart rate was measured with a digital counter.

3. Effects on autonomic nervous system
Pupil size in male rats was observed 1 day before and 1 h, 3h, 6 h, 1 day, 2 days, 3 days, and 7 days after oral administration of the test substance (5 animals/dose).
The effects on the phrenic nerve-diaphragm of male rats was evaluated in vitro by applying the test substance at concentrations of 0.1, 1, 10, and 100 µg/mL (4 animals/dose). Four preparations of the isolated phrenic nerve diaphragm were used to study the effects of the test substance on the muscle contraction induced by direct or indirect stimulation. The test substance was cumulatively applied every 5 min to the medium in the Magnus tube. The contraction was expressed as % calculated with reference to the value recorded immediately before the vehicle. Bipolar electrodes for direct and indirect stimulation were located on the diaphragm and on the phrenic nerve, respectively, and the preparation was suspended in the Magnus tube filled with aerated Krebs-Ringer´s solution. Direct stimulation (8 msec) and indirect stimulation (0.05 msec) at supramaximal voltage were applied alternately with an interval of 5 s with an electric stimulator. Contraction was recorded isometrically.

4. Effects on digestive organs
Transport activity of the small intestine in male mice was studied 1 h after oral administration of the test substance (8 animals/dose). The mice were deprived of food for about 16 h before the experiment. Charcoal suspension was administered orally in a volume of 10 mL/kg 1 h after the administration of the test substance. Mice were euthanized with ether 30 min after the administration of the charcoal and their intestines were isolated. The mobility of the charcoal (%) was calculated by comparing the length of charcoal transported in the small intestine with the total length. Charcoal powder was uniformly suspended in 10% acacia aqueous solution to give a concentration of 10% (w/v).

The effects on the ileum of male guinea pigs was evaluated in vitro by applying the test substance at concentrations of 0.1, 1, 10, and 100 µg/mL (4 animals/dose). Four preparations of the isolated ileum were used to study the effects of the test substance on the spontaneous motility and agonist-induced contraction. After confirming contraction induced by acetylcholine (50 ng/mL, 30 s) effects of the test substance on spontaneous motility were observed for 5 min in the presence of the test substance. Thereafter, contraction was induced by acetylcholine (50 ng/mL), histamine (50 ng/mL), or high potassium concentration (50 mM). The contraction was expressed as % calculated with reference to the respective mean values of two consecutive values recorded immediately before the vehicle.

5. Effects on skeletal muscle
Grip strength in male rats were observed 1 day before and 1 h, 3h, 6 h, 1 day, 2 days, 3 days, and 7 days after oral administration of the test substance (5 animals/dose).

6. Effects on renal function
Urine of male rats was collected to evaluate renal function during 3 h collection period after loading physiological saline, which was initiated 1 h following the oral administration of the test substance (5 animals/dose). Effects on urine volume, urinary electrolyte excretion, osmolality, pH, occult blood, protein, ketone, and glucose were examined.

II. RESULTS AND DISCUSSION

A. Effects on central nervous system

1. Male and female mice (toxicological signs and body weights)
In male mice one animal of the 40 and 100 mg/kg group and all animals of the 250 mg/kg dose group died within 6 h after the administration. In female mice two animals of the 250 mg/kg group died within 3 h after administration. Abnormal signs observed in the survived mice disappeared within 2 days. No distinct abnormalities were observed for male and female mice at 16 mg/kg or less. No distinct changes were observed for body weights at the doses up to 250 mg/kg.
Nonspecific abnormal signs including both excitatory and inhibitory signs were observed at 40 mg/kg upwards. The abnormal signs consisted of a decrease in alertness and visual placing, manifestation of passivity and thrashing, a decrease in spontaneous activity and reactivity, exaggerated touch and startle response, manifestation of Straub tail, tremors, and clonic convulsions, prostrate, staggering gait, a decrease in righting reflex, limb tone, grip strength, body tone, ipsilateral flexor reflex (IFR), manifestation of salivation, hypothermia, whitish skin, and a decrease in respiratory rate.

2. Male rats (toxicological signs, body temperature, and body weights)
One animal of the 625 mg/kg group died within 2 days after administration. Abnormal signs observed in the survived rats disappeared within 7 days. No distinct abnormalities were observed at 16 mg/kg or less. Body weights were significantly decreased 1 day through 3 days at the highest dose. No distinct changes were observed for body weights at the doses up to 250 mg/kg.
Oral administration of the test substance dose-dependently produced excitatory abnormal signs at 40 mg/kg or more. The abnormal signs consisted of manifestation of thrashing, manifestation of Straub tail, clonic convulsions, prostrate, staggering gait, salivation, urination, shivering, and whitish skin.
Body temperature was transiently decreased 1 and 3 h after administration of 100 mg/kg or more. At 250 and 625 mg/kg increased values of 2 and/or 3 days were observed, but seemed not to be related to the administration of the test substance.

3. Male mice (hexobarbital sleeping time)
No distinct changes were observed for the sleeping time up to 100 mg/kg, although 6/8 animals of the 100 mg/kg group died 30 min through 3.5 h after the injection of hexobarbital.

B. Effects on Respiration and circulation

1. Male rabbits (heart rate, blood pressure, electrocardiogram, respiration)
Injection of vehicle (5% Tween 80 aqueous solution containing 15% DMSO) produced a decrease in blood pressure during the last half of injection and thereafter, a slight increase in blood pressure that lasted for a few minutes. Injection of 3 mg/kg test substance elicited bursts in electrocardiogram related to convulsions and slightly increased systolic blood pressure. Injection of 12 mg/kg test substance elicited remarkable increase in blood pressure and tidal volume a few minutes after injection. Thereafter, low level of blood pressure continued during several ten minutes before death. All animals died at that dose. Cardiovascular collapse and decreased respiratory rate occurred immediately before death. No changes related to the test substance were observed at the dose of 0.75 mg/kg.

C. Effects on autonomic nervous system

1. Male rabbits (pupil size)
Mean pupil size of the 250 mg/kg group was slightly but significantly increased 3 h after administration. As this effect was only observed in some animals and was not observed in the other dose groups or at the other time points this was not considered to be treatment related.

D. Effects on digestive organs

1. Male mice (transport activity of the small intestine)
Transport activity of the small intestine was slightly decreased at the doses of 40 mg/kg or more. The mobility of the 100 mg/kg group decreased to 70% of the control group. Changes related to the test substance were not observed at the doses of 16 mg/kg or less. Statistical significance is noted for the value of the 2.6 mg/kg group. However, it seems to be accidental because significant changes were not observed at the higher two successive doses.

2. Male guinea pigs (effects on isolated ileum)
Application of the test substance at concentrations of 10 µg/mL or more increased motility. The increase observed at 100 µg/mL was still observed after washing out the test substance. The changes at 1 µg/mL were marginal and no distinct changes were observed at lower concentrations. Application of the test substance inhibited histamine-induced contraction to about 90% of pre-application at 10 µg/mL or more. Application of the test substance also inhibited high potassium-induced contraction to about 80% at 1 µg/mL or more. Acetylcholine-induced contraction was not significantly affected up to concentrations of 100 µg/mL.

E. Effects on skeletal Muscle

1. Male rats (effects on grip strength and on isolated phrenic nerve-diaphragm preparation)
No test substance related changes of grip strength were observed at doses up to 625 mg/kg. Occasional changes at 100 and 250 mg/kg were considered to be not treatment-related due as the values were close to the pre-administration values and the control values were small.
Treatment with 1 µg/mL or more increased both direct (muscle) stimulation-induced and indirect (nerve) stimulation-induced contraction. Direct contraction was increased more strongly than the indirect contraction (50% vs. 10-20%). No effects were observed at concentrations of 0.1 µg/mL.

F. Effects on renal function

1. Male rats (urinalysis)
After administration of the test substance at 100 mg/kg an increased glucose concentration was observed in the urine. No effect on glucose concentration was observed at 40 mg/kg or less. No changes of the other parameters were observed at the doses up to 625 mg/kg. Although no statistical significance was noted in the 625 mg/kg group, 3/4 survived animals in the group exhibited severe and extreme scores on glucose. The high incidence suggests that urine glucose of the group is increased by the test substance. On the other hand statistical significance in urinary K and Cl excretions of the 100 and 250 mg/kg groups seems not to be related to the administration of the test substance, because the values of the 625 mg/kg group are larger than those of the lower groups but were not statistically significant.

III. CONCLUSIONS

Alphacypermethrin (batch 351, purity 93.2%) was tested in a general pharmacological study in mice, rats, guinea pigs and rabbits. The test substance produced acute toxicities through its action on the nervous and cardiorespiratory systems at sublethal doses close to lethal doses.

Alphacypermethrin: Effects of antidotes on acute toxicity
AL-452-002
Guidelines: <none>
GLP: yes
(certified by Ministry of Agriculture, Forestry and Fisheries of Japan, Japan)
Remark: This study was not submitted within the first Annex I inclusion. As this study is supplemental, the data are only shortly summarized.

Executive Summary

In 1999 an antidote study with methocarbamol, mephenesin and halothane was conducted in each 10 male rats to investigate their possible use as antidotes in acute oral intoxications. Alpha-cypermethrin (Batch 351, purity 93.2%) was dissolved in corn oil and orally administered at a dose of 125 mg/kg bw to 6 week old male Sprague-Dawley rats. Methocarbamol (100 mg/kg) and mephenesin (100 mg/kg) were subcutaneously treated immediately after, and 4, 8, 12, 16, 20, and 24 hours after the administration of alpha-cypermethrin. Halothane was continuously exposed to the animals in a chamber at a concentration less than 1% up to 24 hours after the administration. The animals were observed 4, 8, 12, 16, 20, 24, 28, 48, 72, 96, 120, 144, and 168h after the administration of the test substance. As control group served 10 animals treated with saline after the intoxication with alpha-cypermethrin.
The saline –treated group produced salivation, convulsions and 6 out of 10 rats died within 48 hours. Methocarbamol and mephenesin did not show any protective effects on the incidence or latency of the toxic parameters, halothane protected the animals from the acute toxic signs (salivation and convulsions) although it had no protective effects on the lethality.

GLP: no

Dietary placental transfer and lactation transfer of zetacypermethrin at 50, 125, 300 ppm in rats from GD 6-20, or GD6-LD21 ([redacted] 2005a)

Executive Summary

The placental and lactational transfer of zetacypermethrin in rats was evaluated in this developmental toxicity study. Test diet containing zetacypermethrin was offered to 6 mated female rats per group from GD 6 through GD 20 (placental transfer animals) or lactation day 21 (lactational transfer animals) at 0, 50, 125, 300 ppm for placental transfer and at 125 ppm for lactational transfer. No mortality and no clinical signs of toxicity were observed. No effect on body weight or food consumtion was observed. At the scheduled necropsy on gestation day 20, 2 females were non gravid. Mean number of pups born, percent males at birth and live litter size were within the historical control data ranges in the placental transfer group. The mean litter percentage of post-implantation loss, live litter size, early and late resorptions at the different dose levels were similar to the control group. The higher percentage of early resorptions at 300 ppm was below the maximum mean value in the laboratory historical control data for definitive studies. In the lactation transfer group no effects on gestation length or the process of parturition were noted in the maternal animals of this group. Furthermore no abnormalities were found regarding mortality, body weight or food consumption. Postnatal survival was within the range of historical control data at most time points. From PND 4 (post selection) to 7 postnatal survival was slightly lower than the historical control data, but was considered a spurious finding. Plasma analyses showed that maternal and fetal plasma are accurate indices of internal exposure to zetacypermethrin during gestation and lactation.

I. MATERIAL AND METHODS

A. MATERIALS

1 ***Test Material:***

Description:	*Zetacypermethrin*
Lot/Batch no.:	*PL03-0427*
Purity:	*81.8%*
Stability:	*Stability in diet was verified for 15 days*

2 ***Dosing:***

Dose levels:	*0, 50, 125, 300 ppm (in diet)*
Dosing period:	*GD 6 – GD 20 or LD 21*

3 ***Test animals***

Species:	*Rat*
Strain:	*Crl:CD(SD)*
Sex:	*Female (6/group)*
Acclimation period:	*yes (length not specified)*

B. STUDY DESIGN AND METHODS

After an acclimation period untreated females were paired with untreated male rats. Test diet containing zetacypermethrin was offered to 6 F0 female rats per group from GD 6 through GD 20 (placental transfer animals) or lactation day 21 (lactational transfer animals) at 0, 50, 125, 300 ppm for placental transfer and at 125 ppm for lactational transfer. A control group was included for placental transfer.
Placental transfer: females were necropsied on GD 20; blood and brain samples were collected from 6 females/group. Blood and brain samples were collected from fetuses (pooled within litters). Samples were analyzed for zetacypermethrin.
Lactational transfer: all females were allowed to deliver. F1 pups were potentially exposed to zetacypermethrin in utero, through nursing during lactation and via direct consumption late in lactation. Blood was collected from all dams on LD 5. Blood and brain samples were collected and pooled from F1 culled pups on post natal day 5. F0 females were necropsied on LD21; blood and brain samples were collected from all dams. Blood and brain samples were collected from 1 weanling/sex/litter on post natal day 21. F0 and F1 samples were analyzed for zetacypermethrin. Samples were analyzed using a gas chromatograph with a µECD and capillary column. Stability in diet of zetacypermethrin was observed for 15 days at room temperature.

II. RESULTS AND DISCUSSION

A MATERNAL OBSERVATIONS (PLACENTAL PHASE)

The following observations were performed in the placental transfer phase with dose groups 0, 50, 125, and 300 ppm.
Mortality: all females survived until necropsy day 20.
Clinical signs: no compound-related clinical signs were noted.
Body weight: main bw gain were slightly decreased at 300 ppm but did not affect the body weight.
Food consumption: was not affected.
Parturition: at the scheduled necropsy on gestation day 20, 2 females were non gravid.
Histopathology:
GD 20 laparohysterectomy (placental transfer group): Mean number of pups born, % males at birth and live litter size were within the historical control data ranges.
The mean litter percentage of postimplantation loss, live litter size, early and late resorptions at the different dose levels were similar to the control group. The higher % of early resorptions at 300 ppm was below the maximum mean value in the laboratory historical control data for definitive studies.

B MATERNAL OBSERVATIONS (LACTATIONAL PHASE)

The following observations were performed in the lactational transfer phase with dose groups 0 and 125 ppm.
Mortality: All females delivered offspring and survived to the scheduled necropsy on lactation day 21.
Body weight: was not affected.
Food consumption: was elevated as is commonly seen in nursing rats.
No effects on gestation length or the process of parturition were noted in this group.

C LITTER DATA F1

Postnatal survival from PND 4 (post selection) to 7 was slightly lower than the historical control data. This effect was not seen in the developmental neurotoxicity study. Therefore, the effect on PND 4-7 survival in this study is considered a spurious finding and not treatment-related. In addition, postnatal survival on PND 0, 0-1, 1-4 (preselection), 7-14, 14-21, birth to PND 4 (preselection), and PND 4-21 ((postselection), was within the range of historical control data. Mortality was not considered to be compound-related due to the small sample size (6 dams/group).

D TOXICOKINETIC ANALYSIS IN BLOOD

Gestation day 20:
Dams: the results of gestation day 20 control group samples probably reflect interference from an unidentified source (2 large early-eluting peaks). The levels found in the maternal plasma samples for the test-article groups show the expected increase in plasma with the dose.

Fetal plasma: low levels were detected in fetal plasma samples. Again, the control group was contamined with an unidentified source (2 large early eluting peaks). Mean concentration of zetacypermethrin in fetal plasma were lower than those in maternal plasma at all dose levels on GD 20 suggesting a minimal transplacental transfer.

Lactational day 5 and 21:
Plasma levels in F0 females were similar for lactational day 5 and 21 but higher than those measured on GD 20 reflecting higher lactational compound consumption and a higher plasma level for offsprings on both lactation day 5 and 21.

III. CONCLUSION

The present results show that maternal and fetal plasma are accurate indices of internal exposure to zetacypermethrin during gestation and lactation. RMS (Belgium) agreed that the increased incidence of early resorptions seen at top dose is not compound-related because these effects were not seen in the next reported study performed with somewhat higher doses. The historical control data are not clearly reported in this study making the use of these data difficult.

[see KCA 5.8.2/5 2006/7013990]

Measurement of zetacypermethrin in milk following dietary administration at 125 and 375 ppm from GD 6 to LD 17 [redacted] 2004)

Executive Summary

The dietary transfer of zetacypermethrin into the milk of female rats and the effect of the in utero and post-natal exposure through milk on the offspring was evaluated in this study. Groups of 15 mated female rats (Crl:CD (SD) IGS BR) were exposed to zetacypermethrin at dietary dose levels of 125 or 375 ppm from gestation day 6 through lactation day 17.
No mortality was observed. Impaired use of left hind limb was seen in 3 females at top dose. Slight reduction of body weight gain during gestation days 6-9 and lactation days 1-4 and lower body weights on lactation days 4-17 were observed in the 375 ppm group. Food consumption was also lowered during gestation days 6-9 and during lactation days 1-17 in the high dose group. Gestation length and parturition were unaffected by the compound. Mean offspring weights were lowered at 375 ppm throughout the post natal period and in the 125 ppm group during PN day 11-17. These effects were considered to be compound-related. Reduced litter weight changes were observed at 125 and 375 ppm. No other abnormalities were observed. Analysis of zetacypermethrin in milk samples show that zetacypermethrin was detected in the milk of nursing pups following dietary administration to the mothers. Levels were dose-related and time-related with a plateau on lactation day 11.
The results of this study indicate that dietary administration to mothers permits to have transfer from food to milk and to quantify exposure of pups via milk.

I. MATERIAL AND METHODS

B. STUDY DESIGN AND METHODS

15 mated female rats (Crl:CD (SD) IGS BR) per group received zetacypermethrin in their diet from gestation day 6 through lactation day 17 at 125 or 375 ppm. The control group contained 10 females. Rats were observed twice daily. Animals were allowed to deliver and rear their offspring to lactation day 17. The offsprings were exposed to zetacypermethrin in utero and through nursing during lactation. On PND 4, litters were culled to 8 pups/litter. All F1 pups were observed daily. On lactation day 4, 11 and 17, milk samples were collected from each dam for the determination of zetacypermethrin. Whole brain samples were also collected from pups on PND 4, 11 and 17 for potential future analysis. All surviving F0 females and surviving F1 pups were euthanized and discarded 17 days postpartum. The test article formulation was found to be homogeneous and contained the amounts specified.

II. RESULTS AND DISCUSSION

A. OBSERVATIONS

MATERNAL OBSERVATIONS
Mortality: there were no mortalities in the study. Postnatal survival was unaffected at the different doses.
Clinical signs: impaired use of left hind limb was seen in 3 females at top dose.
Body weight: while maternal body weight was not affected, mean body weight gain was lowered at 375 ppm during gestation days 6-9 and body weights were lower on lactation days 4-17. Main bw gain was lower during lactation days 1-4.
Food consumption: was lowered during gestation days 6-9 and during lactation days1-17 at top dose.

LITTER DATA F1
The mean number of pups born, live litter size and percent of males/litter at birth were unaffected by treatment. The number of F1 pups found dead and missing, as well as the general condition of all F1 pups were unaffected by maternal exposure.
Mean offspring weights were lowered at 375 ppm throughout the post natal period and in the 125 ppm group during PN day 11-17. These effects were considered to be compound-related. Reduced litter weight changes were observed at 125 and 375 ppm.

B ANALYSIS OF ZETACYPERMETHRIN IN MILK

Analysis of zetacypermethrin in milk samples show that zetacypermethrin was detected in the milk of nursing pups following dietary administration to the mothers. Levels were dose-related and time-related with a plateau on lactation day 11. No residues were found in control group animals. Gestation length and parturition were unaffected by the compound.

III. CONCLUSION

The results of this study indicate that dietary administration to mothers permits to have transfer from food to milk and to quantify exposure of pups via milk.

Report: CA 5.8.2/6
Abass K. et al., 2012a
Characterization of human cytochrome P450 induction by pesticides
2012/1367022
Guidelines: <none>
GLP: no
(certified by <none>)

Executive Summary of Literature

The authors investigated several pyrethroids (alpha-cypermethrin (highest purity available: not given), cypermethrin (cis/trans ratio not given, highest purity available: not given), deltamethrin, fenvalerate and lambda cyhalothrin together with representatives of organophosphorus, carbamates and other pesticides on their property to induce cytochrome P450 enzymes. A HepG2 transfection system was used to investigate the activation of human PXR via the dual-Luciferase Reporter Assay System (Promega). Activation of mouse and human CAR was investigated in C3A hepatoma cells with a Gal4-responsive luciferase reporter. Induction of CYP-mRNA was investigated by c-DNA synthesis and subsequent real time PCR and in addition enzyme activities of CYPs were investigated in the N-in-one cell culture assay. All pesticides were tested at 10 and 50 µM. These concentrations did not induce significant cytotoxicity, measured as Lactate dehydrogenase release (50 µM alphacypermethrin: 2.4%; cypermethrin: 3.0%). Both alpha-cypermethrin and cypermethrin pyrethroids induced the human nuclear receptor CAR and PXR to the same extent (see Figure 1 of the publication below), induced mRNA release of CYP2A6 (alpha-cypermethrin > cypermethrin), 2B6 and 3A4 (alpha-cypermethrin < cypermethrin), and lead to 3-4 fold induction for CYP2B6 and CYP 3A4 in HepaRG cells. This enzyme induction is in agreement with a CYP3A11 induction in mouse primary hepatocytes. Pyrethroids were rather ineffective on CYP1A2 mRNA release and enzyme induction.

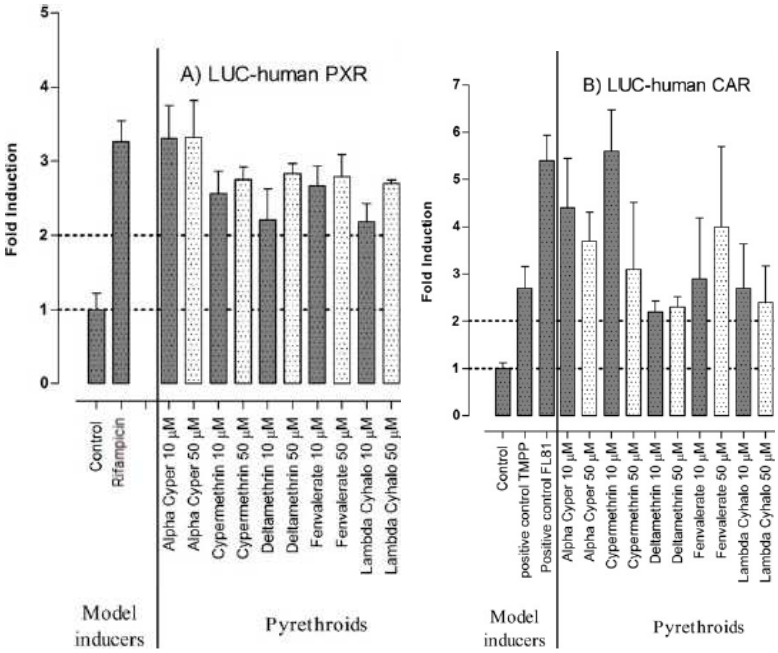

Figure 1 of the publication: Activation of human A) PXR and B) CAR by model inducers and pesticides. Nuclear receptor activation was measured by luciferase reporter gene activity. Results are expressed as mean ± SD of at least three independent experiments.

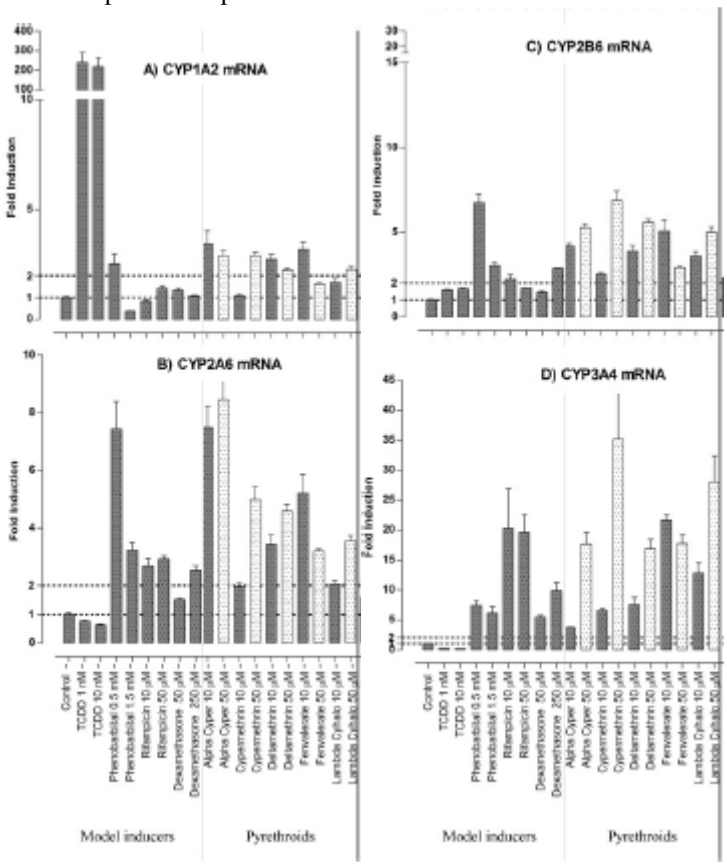

Figure 2 of the publication: Cyp mRNA levels in human HepaRG cell line after 24 h exposure to the test compounds. Total RNAs were isolated and subjected to RT-PCR. The mRNA levels are expressed as relative to the respective control cell level (normalized to 1) and the data are expressed as mean ± SD of six replicates.

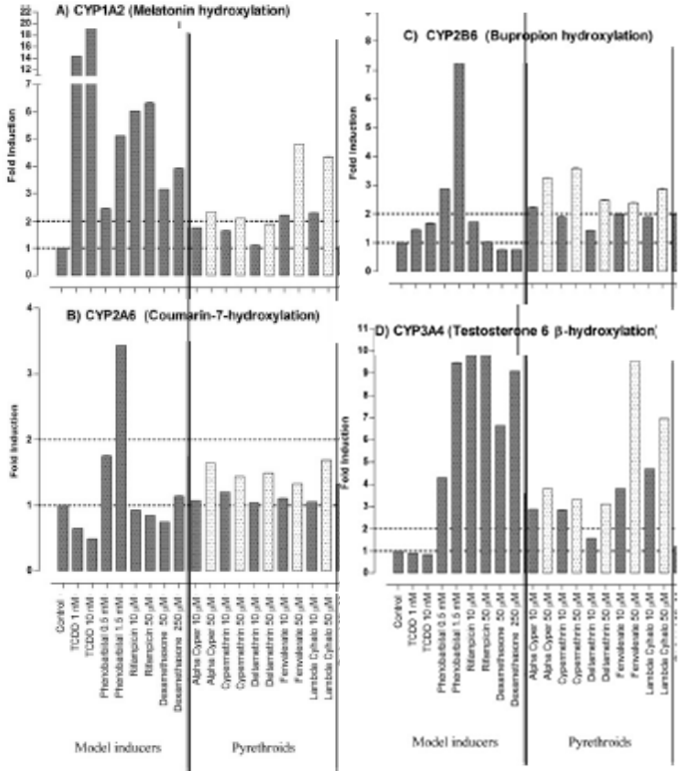

Figure 3 of the publication: A) CYP1A2, B) CYP2A6, C)CYP2B6, D) CYP3A4 enzyme activities measured by N-in-one assay. The enzyme activity levels are expressed as relative to the respective control cell level (normalized to 1) and the data are expressed as mean ± SD of three replicates.

Conclusion of the author: Pyrethroids moderately induced CYP2A6 and CYP2B6 mRNAs, and strongly upregulated CYP3A4 mRNA in HepaRG cells. In contrast to the human nuclear receptor the mouse CAR seems to be much less responsive to the pesticides than the human receptor.

Conclusion of the applicant: The used in vitro test system N-in-one for determination of enzyme acivity is considered as screening assay only (taking into consideration the following report Abass et al., 2013 Doc ID 2013/1416883 in which discrepancies to the single substrate assay were shown). The described data however confirm similarity of alphacypermethrin and cypermethrin with regard to mRNA induction. CYP P450 enzymes are not the main enzymes relevant for metabolic degradation of cypermethrins in humans, therefore, and based on the fact that the liver is not the primary target organ, these data are considered as supplemental information to support the bridging approach but are not considered relevant for risk assessment.

The inhibition of major human hepatic cytochrome P450 enzymes by 18 pesticides: Comparison of the N-in-one and single substrate approaches
2013/1416883
Guidelines: <none>
GLP: no

Executive Summary of Literature

The authors investigated the potential inhibitory interactions of a selection of widely used pesticides (among those alpha-cypermethrin and cypermethrin, deltamethrin, fenvalerate and lambda-cyhlothrin) by the N-in-one assay in human hepatic microsomes (from liver samples obtained from the University Hospital of Oulu) and compared this with a single substrate assay. The inhibitory interactions of tested compounds were investigated at 1, 5, 25, 50, and 100 µM. The respective pesticides were preincubated with the microsomal protein and the substrate for 2 min before the addition of NADPH initiated the reaction. After 20 min the reaction was stopped, protein fraction was removed and supernatant was analysed via LC/MS-MS. Reduced substrate degradation was interpreted as inhibition based on CYP interaction with the pesticide.
The data for alpha-cypermethrin and cypermethrin were extracted from the Supplementary data in the online version, at http://dx.doi.org/10.1016/j.tiv.2012.05.003 and are presented below in Table 1 Supplementary of the publication (see below).

Table 1 Supplementary. IC_{50} values (µM) of the studied pyrethroid pesticides on different human P450 enzymes using pooled human hepatic microsomes as measured by the N-in-one[1] and single substrate[2] approaches.

[1] Each pesticide was added at final concentrations of 1, 5, 25, 50 and100 µMto the incubation mixture for the IC_{50} values determination. The IC_{50} values were determined from three technical replicates from the same human microsomal poolby linear regression analysis from the plot of the logarithm of inhibitor concentration versus percentage of the activity remaining after inhibition using MicroCal Origin 6.0 (MicroCal Software. Inc.. Northampton. MA). The enzyme activities in the presence of inhibitors were compared with the control incubations (incubations with the solvent only). IC_{50} values higher than 100 µM were extrapolated based on the linear regression analysis obtained from tested concentrations.
[2] IC_{50} values (µM) measured by single substrate assays were obtained from our previous study (Abass et al. 2009) for comparison between the assays.
[3] 1-OH-MDZ
[4] SO_2-OME

Alpha-cypermethrin inhibited CYP2E1 and CYP3A4 with IC50 values of 4.0 and 3.4 µM in the N-in-one assay. This enzyme inhibition was not reproduced in the single substrate approach.

Conclusion of the author: The N-in-one screening assay seems useful and reliable for most CYP activities when a comprehensive and quick evaluation of potential interactions with CYPs is needed.

Conclusion of the applicant: The enzyme inhibition with alpha-cypermethrin seen in the N-in-one screening assay with CYP2E1 and CYP3A4 is highly questionable because it was not reproducible in the single substrate assay. In the single substrate assay enzyme inhibition is at a compareable range between alpha-cypermethrin and cypermethrin.

Classification of study: Supplementary information

Report: CA 5.8.2/8
Nasuti C. et al., 2006a
Dopaminergic system modulation, behavioral changes, and oxidative stress after neonatal administration of Pyrethroids
2007/1070386
Guidelines: none
GLP: no

Executive Summary of Literature

The authors investigated the effects of cypermethrin (cis/trans:63/37%; purity: 92.4%,) and permethrin (cis/trans:75/25%, purity: 94%) on the behavior of rats after neonatal exposure (postnatal day (PND) 6 or 8 to PND 15) via gavage in corn oil. Furthermore, the level of oxidative stress and the effects on the dopaminergic system were determined. Each group consisted of 10 dams, each with 4 male pups treated with vehicle alone, 1.49 cypermethrin or 34.05 mg/kg bw permethrin dissolved in corn oil by oral gavage (5 mL/kg bw). The doses correspond to 1/10 of the LD_{50} values. Litter weight was recorded at PND1, PND7, PND14 and PND21.
Neurotransmitter status and degradation (dopamin, 3,4-dihydroxyphenylacetic acid (DOPA) and homovanillic acid (HVA)) in striatum was investigated in 10 animals per group (PND35).
Open field studies (number of ambulatory episodes, number of rears, number of grooming movements, number of entries into the center) were conducted at PND21 and PND35 with 10 rats per group.
Antioxidant activities (GPx and SOD activities) in plasma were investigated in the blood of six rats per group (PND35). Protein oxidation (determination of carbonyl group content) and lipid peroxidation (oxidation index) was determined in the striatum and in erythrocytes. GSH content was determined in the cells from striatum and the respiratory burst in monocytes was determined using Lucigenin as an indicator of superoxide anion radicals.

Results:
Rats treated with cypermethrin or permethrin showed no signs of pyrethroids poisoning or gross behavioral abnormalities throughout the experimental period and no effect on body weight was observed, when comparing control and treated groups (see Figure 1 of the publication, below).

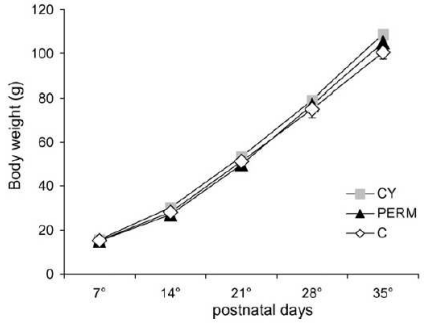

Fig. 1. Body weight in CY-treated (■), PERM-treated (▲) and control rats (◊) during 35 postnatal days. Data are presented as mean ± S.D.
*$P < 0.05$ vs. control (C).

In the open field observation no significant modifications were observed on PND21 (see Fig. 2 of the publication below), whereas on PND35 pyrethroid treatment increased the spontaneous locomotor activity of rats in comparison with the control group (see Fig. 3 of the publication below). In addition a significant increase of rearing was observed after treatment with cypermethrin on PND35. With regard to anxiety-like behavior, the cypermethrin-treated rats had more entries and time spent in the center than control animals.

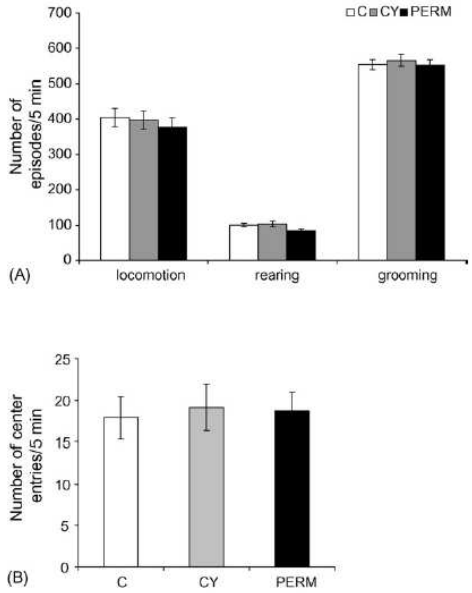

Fig. 2. Effects of neonatal cypermethrin (CY) and permethrin (PERM) exposure on locomotion, rearing and grooming (A) and anxiety test (B) in rats observed at 21 days of age. Data are expressed as mean ± S.D. for 10 rats ($n = 10$L). $^{*}P < 0.05$ vs. control (C).

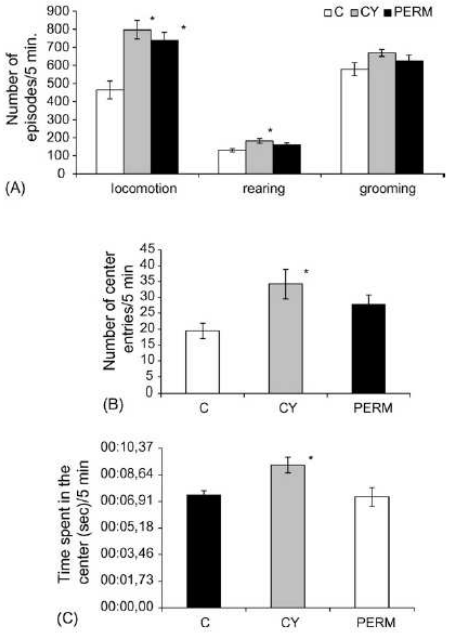

Fig. 3. Effects of neonatal cypermethrin (CY) and permethrin (PERM) exposure on locomotion, rearing and grooming (A) and anxiety test (B and C) in rats observed at 35 days of age. Data are expressed as mean ± S.D. for 10 rats ($n = 10$L). $^{*}P < 0.05$ vs. control (C).

Monoamine levels: On PND 35 pyrethroid-treated animals exhibited lower striatal dopamine levels. No significant changes were observed in DOPAC levels, while HVA concentration increased significantly in rats treated with cypermethrin (26±5.2 pmol/mg tissue) and permethrin (24±4.2 pmol/mg tissue) compared to the control animals (17±1.6 pmol/mg tissue).

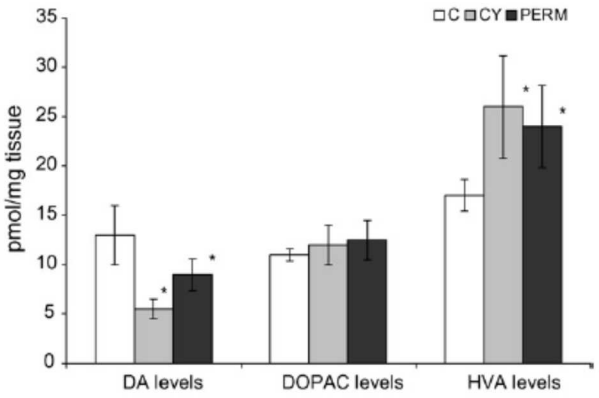

Fig. 4. Levels of dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC), and 3-methoxy-4-hydroxyphenylacetic acid (HVA) in striatum cell of rats from control group (□), CY-treated (▨) and PERM-treated (■) groups. Data are presented as mean ± S.D. for four rats. Measurements were performed in triplicate for each sample. $^{*}P < 0.05$ vs. control (C).

Plasmatic superoxide dismutase (SOD) and gluthathione peroxidase (GPx) activities: Pyrethroid-treatment led to a decrease of plasmatic GPx activity on PND 35 of approximately 15%. No change was measured in SOD activity (see Fiure 5 of publication below).

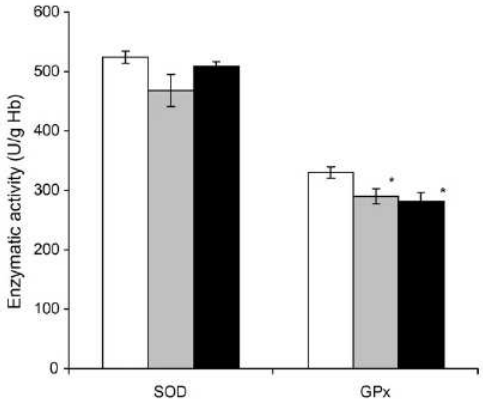

Fig. 5. SOD and GPx blood levels measured in rats, at 35 days of age, from control group (□), CY-treated (▨) and PERM-treated (■) groups. Data are presented as mean ± S.D. for six rats. $^{*}P < 0.05$ vs. control (C).

Protein oxidation (measured as Carbonyl groups) and lipidperoxidation (measured as Oxidation index) in striatum and erythrocytes: A significant increase of protein oxidation in striatum was observed in both pyrethroids-treated groups, whereas no changes in the lipidperoxidation (see Fig. 6 of the publication below) were seen. In erythrocytes no protein oxidation was found but significant increased lipidperoxidation (see Fig. 9 of the publication, below).
Effect on plasma membrane fluidity in striatum and erythrocytes: No physicochemical change of plasma membrane phospholipid fluidity was seen in striatum or in erythrocytes.

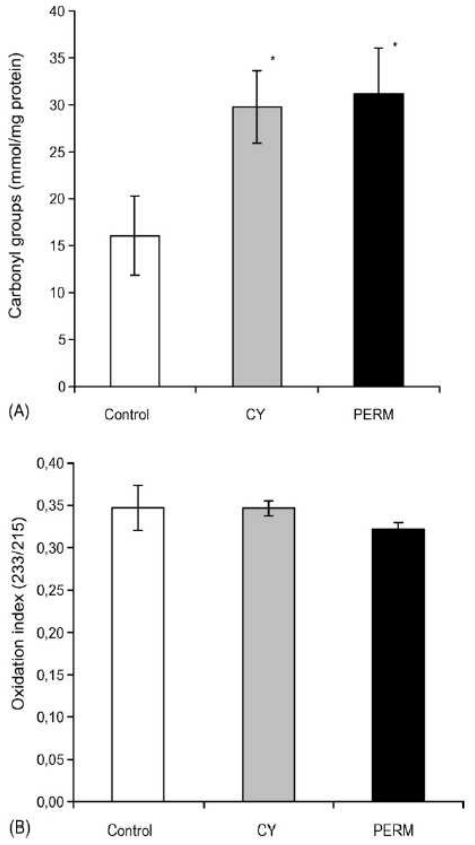

Fig. 6. Effect of pyrethoids on protein carbonyl formation (A) and oxidation index measured on lipids extracted (B) in striatum cells of rats from control group (□), CY-treated ( ) and PERM-treated (■) groups. The results are indicated as mean values ± S.D. for six rats. *$P < 0.05$ vs. control.

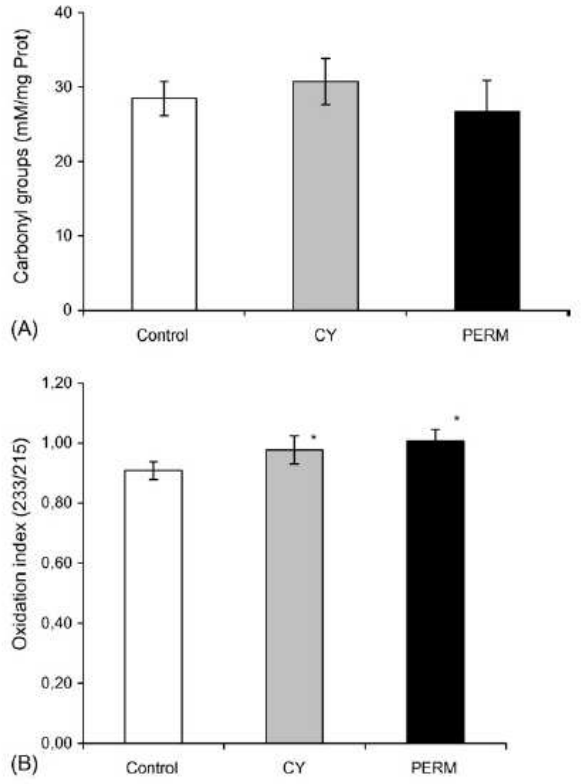

Fig. 9. Effect of pyrethoids on protein carbonyl formation (A) and oxidation index measured on lipids extracted (B) in erythrocytes of rats from control group (□), CY-treated ( ) and PERM-treated (■) groups. The results are indicated as mean values ± S.D. for six rats. *$P < 0.05$ vs. control.

GSH levels in striatum cells (see Fig. 8 of the publication below): Data indicate increased levels in the cypermethrin-treated animals and decreased levels of GSH in the permethrin-treated animals.
Furthermore the respiratory burst behavior in monocytes from rats after activation with PMA showed a decreased superoxide anion production in the monocytes of rats treated with cypermethrin and permethrin (see Fig. 10 of the publication, below).

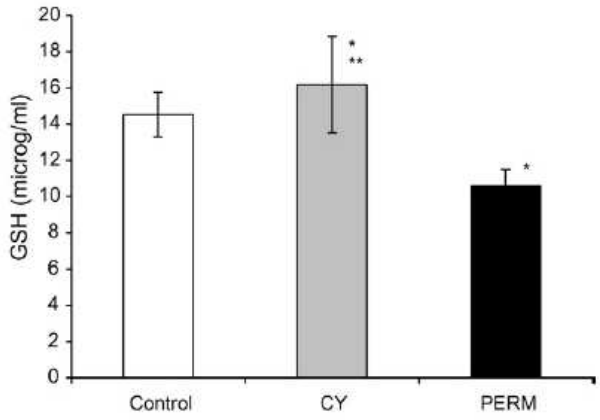

Fig. 8. GSH level in striatum cells of rats from control group (□), CY-treated (▒) and PERM-treated (■) groups. Data represent the means ± S.D. for six rats. $^{*}P<0.05$ vs. control, $^{**}P<0.05$ vs. PERM. For experimental details, see Section 2.

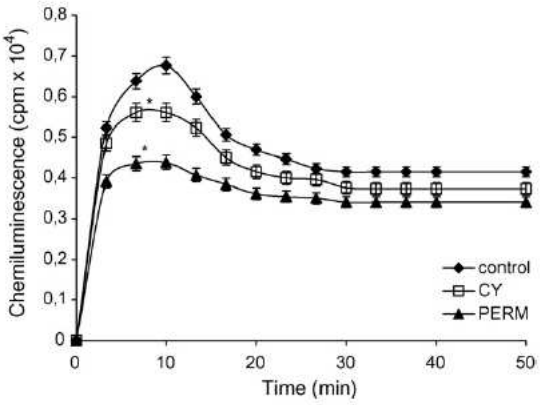

Fig. 10. Time course of lucigenin-amplified chemiluminescence of monocytes in rats from control group (♦), CY-treated (□), and PERM-treated (▲) groups. Monocytes were stimulated with 3×10^{-4} mol/L phorbol myristate acetate. Chemiluminescence was measured as counts per minute (cpm). The results are indicated as mean values ± S.D. for six rats. $^{*}P<0.05$ vs. control.

Conclusion from the author: The increased locomotion and rearing on PND 35 indicates dopaminergic impairment; the lack of increased locomotion on PND 21 indicates possible behavioral alterations by pyrethroids that are not observed directly but later in the life of the animal. From the two hypothesis presented to explain lower dopamin levels in striatum after cypermethrin or permethrin treatment (increased DA turnover and reduced DA biosynthesis) the data suggest an increased catabolic pathway of DA. Accelerated DA turnover induces formation of reactive oxygen species. This is discussed to be in line with reduced blood glutathione peroxidase levels and increased protein oxidation in striatum. No change in lipid peroxidation in striatum indicates that brain antioxidants can partially protect from free readicals produced by DA degradation. GSH levels, as representative for brain antioxidants, were found to be increased for cypermethrin but reduced for permethrin. The authors attributed this to increased hydrophilicity of cypermethrin. A further difference to previous studies was seen with regard to erythrocyte plasma fluidity which shows alterations on adult rats but not in rat pups, although both showed alteration in lipid peroxidation as only damage assessed in erythrocytes. That protein oxidation is observed in striatum but not in erythrocytes is discussed as result of different distribution of pyrethroids in brain and blood and by DA oxidation products that bind to proteins. An immunosuppressive effect evaluated as reduced superoxide anion production in rat monocytes was seen for cypermethrin and permethrin and is suggested to be based on altered signal transduction or NADPH oxidase compex formation. In conclusion the data indicate that neonatal exposure to pyrethroids during the critical period of growth has long-term effects on the biochemistry and behavior of male rats.

Comment from the applicant: The publication shows reporting deficiencies, for example with regard to unclear treatment period (PND 6-15 or PND 8-15, both is mentioned), with regard to number of samples and replicates (some measurements are not quantified), and with regard to clinical observations (interval and the timespan of observation is not mentioned). Furthermore the work shows some methodical deficiencies as the data are produced with cypermethrin of low purity, and with only one dose which hampers differentiation between incidental and treatment related effects, furthermore it is produced with litters of only one sex, which might induce a systemic confounder. MA was performed twice and only over a very short period of time (2 min adaptation, 5 min recording) which is not adequate to demonstrate intra-session habituation. Therefore the significant changes of MA assessment on PND 35 are of questionable relevance, furthermore the data are not discussed in consideration of historic control data. Repeated maternal separation which is needed for direct pup dosing is considered to be a systemic confounder for increased motoractivity and increased number of center entries for Wistar rats [see KCA 5.8.2/9 2015/1001752]. Furthermore some results suggest inconsistencies of the findings so that the reliability of the data is questioned (see figure 8 of the publication: GSH level in striatum shows opposing trends for cypermethrin and permethrin, and for cypermethrin the effect is hardly significant compared to control (although otherwise discussed). Measurement of DA and its metabolites in striatum are expressed in terms of picomoles per gram of tissue, although weighing of striatum is not mentioned in the report.
The immunosuppressive effect described in the study is not confirmed in the Immunotoxicity study performed with alpha-cypermethrin (see CA 5.8.2/2).

However, these data indicate that cypermethrin application to pups from PND6/8 onwards without preexposure of dams does not lead to clinical signs of neurotoxicity at a dose level of 1.4 mg/kg bw. Taking the purity and isomeric composition into account, this indicates that alpha-cypermethrin at a level of 0.44 mg/kg bw is not considered to induce neurotoxicity.
This is taken up in the chapter CA 5.7 when discussing developmental neurotoxicity.

In conclusion, based on the above discussed deficiencies this study is of insufficient quality, furthermore based on the unrealistic and hazard driven exposure technique this study is not considered relevant for human risk assessment.

Classification of study: Supplemental information

Report: CA 5.8.2/10
Flaskos J. et al., 2006a
The effects of Diazinon and Cypermethrin on the differentiation of neuronal and glial cell lines
2007/1070387
Guidelines: none
GLP: no

Executive Summary of Literature

The authors investigated the effects of cypermethrin (in the chapter material and methods alpha-cypermethrin is mentioned, purity: no data) and diazinon (purity: no data) on the differentiation of neuronal (mouse N2a neuroblastoma) and glial (rat C6 glioma) cell lines. Cell differentiation was either induced by incubation in serum-free medium containing 0.3 mM dibutyryl cAMP (N2a cells) or by replacing cAMP with 2 mM sodium butyric acid (C6 cells). Cell differentiation was monitored for 24 h in the presence or absence of test substances (1 and 10 µM). Cells differentiated in the presence and absence of pesticide were fixed, stained with Coomassie Brilliant blue dye, and the outgrowth of axon-like processes in N2a cells and process outgrowth in C6 cells were determined. Cell growth and viability was assessed with the MTT assay and the acetylcholinesterase activity was determined by the method of Ellmann, adapted for a microtiter plate format.
Conclusion of the author: Cypermethrin had no significant effect on process outgrowth in either differentiating neuronal cell line.
Conclusion of the applicant: Both substance (cypermethrin or alpha-cypermethrin) and purity is not clear. Therefore the result is not further considered, however under the conditions of the study no direct effect on neurite outgrowth was seen.

Classification of study: Not further considered

Effects of alpha- and theta-Cypermethrin insecticide on transient outward potassium current in rat hippocampal CA3 neurons
2008/1102217
Guidelines: none
GLP: no

Executive Summary of Literature

The authors investigated the effects of alpha-cypermethrin (purity: no data) and theta-cypermethrin (purity: no data) on the transient outward potassium (I_A) channels in freshly dissociated hippocampal CA3 neurons of rat, using whole-cell patch clamp technique. Cypermethrins were first dissolved in DMSO and then in extracellular solution. Cypermethrins were used at concentrations of 1, 10, and 100 nM. The peak amplitudes of I_A were increased about 5%, 9%, and 24% after incubation with alpha-cypermethrin in a dose-dependent manner. In contrast, incubation with theta-cypermethrin decreased the amplitudes of I_A by about 12%, 22%, and 54%, respectively. For analysis of the current–voltage (I–V) relationship, neurons were held at -70 mV. I_A currents were obtained by depolarizing steps from a command potential of -60 to +90 mV at 10 mV steps. Upon the application of alpha-cypermethrin, the amplitudes of I_A currents were enhanced differently at different membrane potential, but the amplitudes of I_A currents at different membrane potential were reduced by theta-cypermethrin (see Fig. 1 of the publication below).

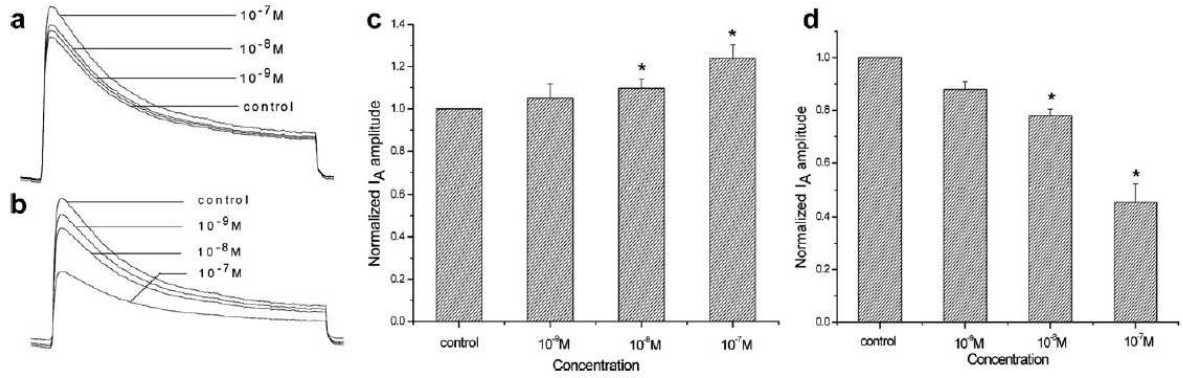

Fig. 1. Dose-dependent effects of alpha-cypermethrin and theta-cypermethrin on I_A. (a) I_A valves were increased at different concentrations of alpha-cypermethrin. (b) I_A valves were decreased at different concentrations of theta-cypermethrin. (c) Dose-dependent effects of alpha-cypermethrin on I_A ($n = 6$, $^*P < 0.05$ *vs* control). (d) Dose-dependent effects of theta-cypermethrin on I_A ($n = 6$, $^*P < 0.05$ *vs* control).

The membrane potential at half-activation of I_A activation curve was significantly shifted to the negative potentials at 10 and 100 nM alpha-cypermethrin and theta-cypermethrin. The membrane potential at half-activation of I_A inactivation curve was significantly shifted to the negative potential at all theta-cypermethrin concentrations but not with alpha-cypermethrin. Theta-cypermethrin and lower alpha-cypermethrin concentrations (1 and 10 nM) had no marked effect on the recovery of I_A from inactivation. Incubation with 100 nM alpha-cypermethrin prolonged the time constants for the recovery from inactivation kinetics of I_A.

Conclusion of the author: These results suggest that alpha-cypermethrin and theta-cypermethrin exhibit different effects on the transient outward potassium channels but are both able to modulate potassium channels in CNS.
Conclusion of the applicant: The report lack information on purity of used substances. However, the data indicate that cis 2-Isomers of cypermethrin (alpha-cypermethrin) and Trans 4 isomers of cypermethrin (Theta-cypermethrin) both act on the outward potassium channel. This is considered as a further proof for the Bridging rationale between cypermethrins. How far these in vitro data are relevant for the invivo situation is unclear.

Effect of alpha-Cypermethrin and theta-Cypermethrin on delayed rectifier potassium currents in rat hippocampal neurons
2009/1130985
Guidelines: none
GLP: no

Executive Summary of Literature

The authors investigated the effects of alpha-cypermethrin (purity: no data) and theta-cypermethrin (purity: no data) on the delayed rectifier potassium current (I_K) in hippocampal neurons of rat, using whole-cell patch clamp technique. Cypermethrins were first dissolved in DMSO and then diluted directly in artificial cerebrospinal fluid. Cypermethrins were used at concentrations of 1, 10, and 100 nM and the final DMSO concentration was <0.1%. Measurements for data analyses were made only at steady-state amplitudes of I_K. Holding potential was -50 mV. I_K was elicited by applying a single depolarizing voltage pulse to +70 mV following a 120-ms prepulse at -110 mV with a 50-ms interval at -50 mV to inactivate I_A. The application of different concentrations alpha-cypermethrin and theta-cypermethrin produced a dose dependent effect on I_K amplitude. A dose-dependent decrease of 26%, 34%, and 40% by alpha-cypermethrin and of 5%, 27%, and 53% by theta-cypermethrin was observed (see Figure 1 of publication below).

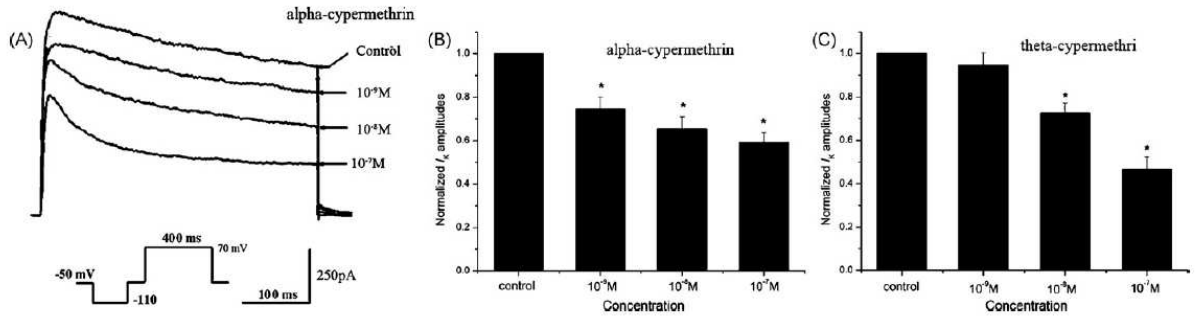

Fig. 1. The effects of cypermethrin on I_K. (A) Original traces of I_K before and after the application of alpha-cypermethrin at different concentrations showing the inhibitory effects of cypermethrin on the steady-state current amplitudes of I_K. Note that various concentrations of cypermethrin were applied to the same neuron. Voltage protocol was exhibited in the inset. (B) Dose-dependent effects of alpha-cypermethrin on I_K ($n = 8$, $^*P < 0.05$ vs control). (C) Dose-dependent effects of theta-cypermethrin on I_K ($n = 8$, $^*P < 0.05$ vs control). Data are presented as means ± S.E.M. ($n = 8$).

The action of alpha-cypermethrin and theta-cypermethrin were quite comparable with regard to reduction of I_K current amplitudes , decrease of slope factor and shift of the membrane potential at half-activation of I_K inactivation curve to the negative potential.
Conclusion of the author: The present study showed that the relative low concentrations of cypermethrin is related to the electrophysiological activities of rat hippocampal CA3 neurons by effects on the voltage gated delayed rectifier K^+ channels. The cypermethrin induced change of K^+ currents in the hippocampal CA3 neurons may contribute to its neurotoxicity by eliciting abnormal neuronal discharge.

Conclusion of the applicant: The report lack information on purity of used alpha-cypermethrin and theta-cypermethrin. However, the data indicate that cis 2-Isomers of cypermethrin (alpha-cypermethrin) and trans 4-isomers of cypermethrin (Theta-cypermethrin) both act in vitro on the delayed rectifier potassium current (I_K) of hippocampal neurons of rat. This is considered as a further proof for the Bridging rationale between cypermethrins. How far these in vitro data are relevant for the invivo situation is unclear.

Classification of study: Supplementary information

Report: CA 5.8.2/13
Wolansky M.J. et al., 2005a
Relative potencies for acute effects of Pyrethroids on motor function in rats
2006/1051134
Guidelines: none
GLP: no

Executive Summary of Literature

The objective of this report was to characterize individual dose-response curves for in vivo motor function of male Long-Evans rats (age: 55-57 days) as a chosen endpoint and calculate relative potencies for the used pyrethroids (cypermethrin, deltamethrin, beta-cyfluthrin, esfenvalerate, lamda-cyhalothrin, fenpropathrin, resmethrin, S-bioallethrin, permethrin, bifenthrin and tefluthrin). Cypermethrin (Cis/trans: 48.7%/51.3%; purity: 88%) was investigated in 8-18 animals (unclear individual number of animals for each pyrethroid) at 6 different doses between 0.1 – 120 mg/kg bw in corn oil by gavage (dosing volume 1 mL/kg). Motor activity was measured for 1 h using figure-eight mazes, each consisting of a series of interconnected alleys converging on a central arena and covered with transparent acrylic plastic. Testing was performed at the time of peak effects (1.5 h for cypermethrin). No signs of excessive toxicity were observed in the animals treated with cypermethrin. All tested pyrethroids induced dose-dependent decreases in motor activity. ED_{30} values (dose at which reduction of 30% total motor activity in figure-eight maze compared to the corresponding vehicle-treated control group was observed) ranged from 1.2 to 292 mg/kg bw. Cypermethrin showed an ED_{30} of 10.7±1.34 mg/kg bw. The Threshold dose (defined as the highest no-effect dose level at which treated rats would respond with 100% control performance) was calculated to be 4.3±1.14 mg/kg bw.

Comment from the applicant: This publication has been discussed in the RAR of Lambda-Cyhalothrin and was mentioned to lack detailed data as number of animals per dose and detailed results per dose level. The RMS (Sweden) concluded that the study is considered as supporting data only.
Furthermore EPA used this study in the assessment of alpha-cypermethrin as the most robust data set for extrapolating risk for the entity of cypermethrins after conducting a benchmark dose analysis (BMD). The argumentation was that the design of the Wolansky study with measured motor activity at the time of peak effect after exposure to several doses (6 for cypermethrin) in at least 8 animals /group minimize variability and increase the confidence in the body mass dose estimates. Moreover, each pyrethroid was evaluated by the same scientist thus decreased some of the variability associated with neurobehavioral measures.

After BMD analysis the acute dietary risk assessment was performed using the $BMDL_{1SD}$ value of 7.16 mg/kg bw, based on decreased locomotor activity at the BMD_{1SD} value of 11.20 mg/kg bw. BMD_{1SD} is the central estimate of the dose that results in decreased motor activity compared to control animals based upon a 1 standard deviation using Benchmark Dose Analysis, whereas $BMDL_{1SD}$ is the 95% lower confidence limit of the central estimate. EPA further concluded that there is no increase in hazard from repeated exposures to the cypermethrins; therefore, the acute dietary exposure assessment is protective of chronic dietary exposures since acute exposure levels are higher than chronic exposure levels. Accordingly, a dietary exposure assessment for the purpose of assessing chronic dietary risk was not conducted.
This study was used in the context of this submission to demonstrate similarity of potencies within the group of cypermethrins.

Classification of study: Supplementary information

Report: CA 5.8.2/14
Scollon E.J. et al., 2008a
In vitro metabolism of Pyrethroid pesticides by rat and human hepatic microsomes and cytochrome P450 isoforms
2009/1130987
Guidelines: none
GLP: no

Executive Summary of Literature

The objective of this study was to determine the intrinsic clearance (CL_{int}), a measurement of metabolic rate of several Type I and II pyrethroids in rat and human hepatic microsomes; to assess the relative role of oxidative and hydrolytic pathways of these pyrethroids; to investigate the potential interaction of diastereomers of permethrin at the metabolic level; and to screen rat and human P_{450} isoforms for their ability to metabolize pyrethroids. Amongst others, cypermethrin (cis/trans ratio 49/51, purity: > 98%) was used in the experiments.
3 pools of rat microsomes were prepared from 18 male Long-Evans rats (age: 70 days, weight: 275-299 g). Pooled human adult liver microsomes were purchased from CellzDirect (mixed gender pool of 15), Cedra (mixed gender pool of 15), and XenoTech (mixed gender pool of 50). Furthermore supersomes containing specific rat or human P_{450} isoforms were used. Estimates of K_m and V_{max} were determined in rat hepatic microsomes for bifenthrin, S-bioallethrin, bioresmethrin, cis-permethrin, trans-permethrn, and a 40:60 cis/trans permethrin mixture. This determination was done to ensure pyrethroids concentrations in the parent depletion assays described below were << K_m. The assays were conducted in duplicate for each of the three pools of microsomes by measuring the disappearance of parent compounds over 10 min. Assays were initiated by the addition of pyrethroid in 25 µL of methanol to a 3.5-ml incubation mixture containing NADPH at time 0 to attain final pyrethroid concentrations of 0.1, 1, 5, 10, 20, or 50 µM. At time 0, 2, 6, 8, and 10 min, 250 µL aliquots were removed from the mixture for analytical determination. This assay revealed general K_m values between 3.7 and 31.1 µM for the different pyrethroids. Therefore determination of metabolic rate constants in rat and human microsomes were than determined at a concentration of 0.5µM (except for S-bioallethrin: 1µM).
Assays to assess the microsomal hydrolysis of the pyrethroids were conducted following the assay principle described above but in the absence of NADPH. Each incubation, with or without NADPH, was conducted in duplicate using the three different pools of microsomes (n = 3).
Result: The calculation of metabolic rate constants and intrinsic hepatic clearance rates of cypermethrin, determined by summation of all the co-occurring isomers, revealed a higher clearance in the rat relative to human hepatic microsomes. Furthermore rat hepatic microsomes show mainly oxidative (85%) and to a minor extend hydrolytic (15%) cleavage. In contrast human hepatic microsomes show mainly hydrolytic cleavage of cypermethrin (see Table from the publication, below).

CL_{int} and percentage oxidative and hydrolytic metabolism of Type II pyrethroids from rat and human hepatic microsomes

Pyrethroid	Isomer	Species	CL_{int}	Percentage Oxidative	Percentage Hydrolytic
Cypermethrin	49% cis	Rat	284 ± 17	85	15
	51% trans	Human	104 ± 63	N.S.[b]	100

N.S., no significant difference.
[b] The clearance values in the presence or absence of NADPH were not significantly different as assessed by an unpaired t test, $p < 0.05$.

Of the P450 isoforms examined, rat CYP1A1, CYP2C6, CYP2C11, CPY3A1, and CYP3A2 and human CYP 2C8 and CYP2C19 have the most Cypermethrin-metabolizing activity.
Conclusion of the author: Cypermethrin metabolism in rat is mainly oxidative, whereas in human hepatic micorsomes mainly hydrolytic cleavage is observed.

Report: CA 5.8.2/15
Crow J.A. et al., 2007a
Hydrolysis of pyrethroids by human and rat tissues: Examination of intestinal, liver and serum carboxylesterase
2007/1070525
Guidelines: none
GLP: no

Executive summary

In this study the distribution and activities of esterases that catalyze pyrethroid metabolism have been investigated in vitro using several human and rat tissues, including small intestine, liver and serum. Alpha-cypermethrin (99% pure, mixture of isomers) was used together with other pyrethroids. The pyrethroid hydrolysis reactions in human and rat tissue microsomes and cytosols were performed after pre-incubation of pyrethroid substrate with buffer and addition of subcellular fraction at a final protein concentration of 0.5 mg/ml. After 15 or 30 min incubations, a time in which product formation is linear, the reactions were quenched and the hydrolysis products were quantified by HPLC. The different subcellular fractions with the CE protein fractions were either purified or purchased.
Result:
Intestine: The major esterase in human intestine is carboxylesterase 2 (hCE2) located in the microsomal fraction. This fraction was able to effectively hydrolyse trans-permethrin, but not bioresmethrin or deltamethrin. Alpha-cypermethrin was not investigated. Rat intestinal fraction (with CE activity located both in the microsomal and cytosolic fraction) was 4-5 times less active than human intestine carboxylesterases.
Liver: hCE1 and hCE2 were clearly present in both liver fractions. A comparison of hydrolytic kinetic parameters for rat and human hepatic microsomes and cytosol toward trans-permethrin is shown in Table 1 of the publication (below).

Table 1
Kinetic parameters of *trans*-permethrin hydrolysis catalyzed by human and rat hepatic subcellular fractions (microsomes and cytosols)[a]

Species (fraction)	Trans-permethrin		
	K_m (μM)	V_{max} (nmol/min/mg)	CL_{int}[b] (nmol/min/mg/mM)
Rat (microsomes)	19.2±3.2	1.3±0.3	67.7
Rat (cytosol)	24.6	0.56	22.8
Human (microsomes[c])	20.7±3.0	1.1±0.1	53.1
Human (cytosol[d])	3.4±0.8	0.47±0.02	138.2

[a] Rat microsomes and cytosol (pooled) were prepared from another study (Ross et al., 2006). Values (±SE) were obtained by non-linear regression of kinetic plots. The microsomal kinetic data are from Ross et al. (2006). The cytosol kinetic data are from this study.
[b] $CL_{int} = V_{max} / K_m$.
[c] Pooled sample (n=18 individuals).
[d] Pooled sample (n=20 individuals).

The data demonstrate that microsomal degradation is very similar in rat and human, but for cytosol the Km value is much lower in human fraction than in the rat fraction and the intrinsic clearance (CL_{int}) is higher.
Serum: Rat serum possesses 4% of the total hydrolytic capacity in the rat, while human serum did not show any hydrolyzing capacity. The capacity to hydrolyse alpha-cypermethrin was investigated in rat serum at a quite high pyrethroid substrate concentration of 50 µM and specific activity was quite low (<1nmol/min/mL serum)
Conclusion of the author: While the hepatic CEs undoubtedly contribute the bulk of pyrethroid hydrolysis, the major difference between rats and humans when attempting to extrapolate animal studies of pyrethroid exposure is the possibility in rats to hydrolyse pyrethroids via serum CEs.
Conclusion of the applicant: The rather poor metabolic capacity of alpha-cypermethrin in rat serum is not considered a relevant degradation process.

CA 5.8.3 Endocrine disrupting properties

Studies evaluated in the draft monograph of rapporteur member state Belgium of Sep. 1999:
The evaluation of potential endocrine disruption was not a data-requirement at the time of Annex I inclusion of alpha-cypermethrin. However, the regulatory data package of alpha-cypermethrin neither indicates a potential to affect the estrogen or androgen system nor the pituitary-thyroid axis.

The available repeat dose toxicology studies, used to support the pesticide registration for alpha-cypermethrin, showed almost always adverse effects limited to lowered body weight and food consumption, clinical signs of neurotoxicity, and signs of skin irritation. Liver weight increases were frequently seen but were suggested to be the result of an adaptive response due to microsomal enzyme induction. Testes weight changes were seen at doses above the LOAEL in combination with reduced body weight and were, without histopathological correlate, suggested to reflect body weight changes. Increased relative adrenal weight changes were only observed once, in the interim sacrifice in the 78 week mice study, also here as result of reduced body weight. No study revealed any treatment-related histopathological findings in adrenals, epididymides, ovaries, pituitary, prostate, seminal vesicles, thyroid with parathyroids, uterus with cervix, vagina and testes. It is worth to be mentioned as especially the 90 day studies in mice (AL-425-006) and rat (AL-425-007) were histopathologically investigated 1993 and 1994 by [redacted] author of numerous papers on male rodent reproductive pathology. In addition there was no evidence for hormonally induced carcinogenicity in life time studies in rats and mice with cypermethrin and alpha-cypermethrin.

Fertility studies with alpha-cypermethrin (Gharda study), even if poorly documented as stated in the monograph, did not show any adverse effect on parturition, reproduction and lactation response. There was no difference in the total number of pups born to control and treated P0, P1 and P2 mothers. Fertility index and litter size was unaffected. Based on reported “delayed pregnancy in this study in the mid and high dose”, it was concluded that the NOAEL of this study is 5 mg/kg bw/day. In the discussions during the ECCO Meetings the RMS stated that the delayed pregnancy finding was a mis-interpretation. Therefore the overall NOAEL for reproductive properties for Alpha-cypermethrin was > 20 mg/kg bw/d in the Review Report 2004 and it was referred to the cypermethrin dietary multigeneration study which reassures the lack of reproductive effects.
The multigeneration study with cypermethrin listed in the monograph showed lower litter sizes and weights and lower pup weights at parental toxic doses mainly for the first generation at 500 ppm. There were no increases in these effects over the three generations. Fertility was not affected at any dose in any generation. At 10 and 100 ppm there were no adverse effects on parental rats and their litters of any generation. Histopathological investigations in the F2 generation and F3B weanlings showed no pathological changes in ovaries, testes and prostate/uterus, thyroid and parathyroid, pituitary, and adrenals. Based on missing effects on fertility in both studies further studies on sperm parameters were not considered to be required.

In summary, taken the complete set of toxicology studies with alpha-cypermethrin, supplemented with existing cypermethrin studies, there is no indication for human relevant endocrine related effects.

Studies submitted in this AIR 3 dossier (not yet peer-reviewed):

The literature search revealed a huge dataset on studies investigating endocrine related effects of cypermethrin, beta-cypermethrin and alpha-cypermethrin as well as metabolites thereof.

Based on the weight of evidence, alpha-cypermethrin is not predicted to have androgenic or anti-androgenic activity:
Cypermethrin has been repeatedly tested to have no androgenic activity *in vitro*. Although there is evidence for weak anti-androgenic activity *in vitro* for cypermethrin, this is not seen with beta-cypermethrin. Based on the isomeric composition of cypermethrin (8 isomers), beta-cypermethrin (4 isomers of cypermethrin) and alpha-cypermethrin (2 isomers (only cis-2-isomers) of beta-cypermethrin), alpha-cypermethrin is considered more comparable with beta-cypermethrin and therefore is not predicted to have androgenic or anti-androgenic activity in vitro. There is evidence that the anti-androgenic activity of cypermethrin is attributable largely to metabolites. As alpha-cypermethrin consists entirely of *cis*-isomers, which are less susceptible to metabolism, similar activity is not predicted. Mechanistic data indicate that the effects of cypermethrin may not be due to a direct interaction with the androgen receptor.
In vivo, Wu et al., (2008) and Zhang et al (2008) report a week positive response in a Hershberger assay with cypermethrin but not for beta-cypermethrin. Also here, based on the isomeric composition of cypermethrin, beta-cypermethrin and alpha-cypermethrin, a positive response in a Hershberger assay is not predicted for alpha-cypermethrin. However, a number of studies report effects on the testes (weight changes, histopathology and changes in histoarchitecture), spermatogenesis, circulating levels of testosterone, LH and FSH and effects on other tissues of the male reproductive tract. The majority of these studies are limited in some way by the use of inappropriate histopathological techniques or diagnosis; dosing with commercial formulations containing high levels of organic solvent; the use of high dose levels causing significant general toxicity or the absence of information on general toxicity; or the use of intraperitoneal dosing. Nevertheless findings cannot be entirely discounted based on the consistency of responses reported. However, effects do not appear to be characteristic of an endocrine mode of action, but are considered more likely to represent general non-specific testicular toxicity due to oxidative stress. Effects are seen at relatively high dose levels of cypermethrin and beta-cypermethrin in a 15day adult intact rat assay and are associated with general systemic toxicity.
The question remains, if the non-specific testicular toxicity as well as the impairment of sperm parameters is already induced by alpha-cypermethrin, which in general needs to be dosed lower based on the higher neurotoxicity. This was addressed in a separate study with alpha-cypermethrin, which is summarized in detail below. Based on these data, alpha-cypermethrin has proven to induce no effect on reproductive organ weights and histopathology in male rat reproductive organs up to the highest tolerable dose in this assay. In addition no effects on sperm parameters were shown (sperm motility, sperm number and morphology were unaffected). This is thereby the proof that the cis-2 isomers of alpha-cypermethrin alone are not sufficient to induce reproductive organ toxicity even under the worst case scenario of repeated bolus administration.

There is limited evidence for the oestrogenicity(less anti-oestrogenicity) of cypermethrin *in vitro*, and also the evidence for oestrogenicity of alpha-cypermethrin in vitro is restricted to two cell proliferation assays (E-Screen assay) of low comparability showing some proliferative effect. A potential induction of proliferation of MCF-7 cells is not directly attributable to an estrogenic effect; therefore the relevance of this information is questionable. Also here, studies with metabolites indicate that estrogenic effects may be due to metabolites generated in vitro, rather than to the parent substance. Furthermore the respective highly potent metabolites were not formed in vivo with alpha-cypermethrin and furthermore the lower metabolic breakdown of alpha-cypermethrin reduces the potential of activation via metabolism. Anyway, *in vivo*, no positive uterotrophic effect is noted for alpha-cypermethrin in rats and in mice reported by Liang et al., 2005.

Only one study investigated the thyroid receptor interaction of Cypermethrin and its metabolites 3-PBA and DCVA and showed only weak or even no antagonistic effects in the 10 µM dose range, therefore the impact is considered of minor relevance for the human risk assessment.

The aromatase and steroidogenesis assays showed no convincing evidence for an effect of cypermethrin. In vitro-assays with relatively high concentrations of questionable physiological relevance indicated a potential direct effect of cypermethrin but not of M310I011 (3-PBA) on sperm motility.

In order to address potential effects on sperm parameters in a proven sensitive study (positive for cypermethrin and beta-cypermethrin), a 15 day adult male rat assay was performed. The dose levels were chosen in a way that no significant systemic toxicity was induced but that dose levels used in the cypermethrin and beta-cypermethrin were reflected with regard to the underlying alpha-cypermethrin amount. Thereby the study design is considered appropriate to get the information if cis-2 isomers are responsible for the formerly described effects on sperm parameters. This study together with the respective range finder is summarized in detail within the chapter CA 5.8.3/50 and below in short.

Table 5.8.3-1: Summary of not yet reviewed alpha-cypermethrin screening studies

Study	Dosages (mg/kg bw/ day)	NOAEL (mg/kg bw/day)	Main adverse effect	Reference
15-day adult male rat assay Wistar rat Vehicle: Corn oil	M: 2.0, 3.5, 6.6	M: 6.6	none	[redacted] 2014 2014/1289319 RF & 2014/1275120 see CA 5.8.3/50 & 51

Overall there is no convincing evidence for a potential of endocrine activity of alpha-cypermethrin in *vivo* up to dose levels not also causing significant systemic toxicity. A potential non-specific testicular toxicity has been investigated for alpha-cypermethrin in a test system which showed positive outcome for beta-cypermethrin and cypermethrin. This study showed no effects on sex organ weight parameters, no effect on sperm parameters and no indication of any effect on Androgen receptor density. Thereby it is appropriate to conclude that alpha-cypermethrin is neither endocrine active nor does it show testicular toxicity up to maximal tolerable dose levels.

Based on weight of evidence from the available studies and the literature data, the following input in the Annex I listing of alpha-cypermethrin is considered reasonable.

Other toxicological studies (SANCO/11802 data point 5.8)	
Endocrine disrupting properties	No endocrine effects on the oestrogen, androgen or thyroid hormone system.

For convenience of the reviewer brief summaries of the respective peer-reviewed studies used from the monograph as well as summaries from the literature data are provided below. Furthermore the 15 day adult male rat assay is described in detail.

Overview of already peer reviewed studies

RAT studies (see Table 5.8.3-2)

5 Week Feeding Study with WL 85871 (Alphacypermethrin) in rats ([redacted] 1982; SBGR.81.212; DocID: AL-420-003; see CA 5.3)

Alphacypermethrin was given to groups of 10 male and 10 female Wistar rats for 35 days at dietary concentrations of 25, 100, 200, 400, and 800 ppm. The NOAEL was determined to be 200 ppm on the basis of clinical signs of neurotoxicity, effects on body weight and food consumption, and hematology at 400 ppm. Mortality occurred at 800 ppm. Testes weights adjusted for initial body weight were reduced in the highest dose but showed no difference to control after adjustment for terminal body weight, suggesting they reflected bodyweight differences. In female rats no endocrine related organs were investigated. Macroscopic and microscopic investigations were done on testes, seminal vesicles, prostate and epididymides. Two animals in the 800 ppm dose group with general thin or small appearance showed small seminal vesicles (#035, 042), one in addition small epididymides and prostate (#035). In absence of any histopathological changes in the respective organs these changes were considered to be not specific treatment related effects. Therefore, it is concluded that alpha-cypermethrin did not induce substance-related endocrine effects at any dose.

6-Week range finding feeding study in the rat [redacted] 1993; SBTR.93.002; DocID: AL-420-006 see CA 5.3)

Alphacypermethrin was given to groups of 5 male and 5 female Crl: CD BR rats for 42 days at dietary concentrations of 50, 200, 800, and 1200 ppm. Rats of both sexes fed 1200 ppm and males fed 800 ppm were sacrificed during weeks 2 to 4 because of severe treatment related clinical signs. The NOAEL was determined to be 200 pm on the basis of severe clinical signs (hunched posture, piloerection, unkempt appearance), clinical signs of neurotoxicity (high stepping gait, splayed gait, hypersensitivity) and decreased body weights at 800 ppm. Neither absolute nor relative adrenal, testes or ovaries weights were changed.

There were no macroscopic or microscopic treatment-related findings in endocrine organs including uterus. Therefore, it is concluded that alpha-cypermethrin did not induce substance-related endocrine effects at any dose.

A 90-day feeding study in rats ([redacted] 1982; SBGR.81.293; DocID: AL-425-003 see CA 5.3)

Alphacypermethrin was administered to groups of 20 male and 20 female Wistar rats for 90 days at dietary concentrations of 20, 60, 180, and 540 ppm. The NOAEL was 180 ppm, based on decreased body weights and clinical signs of neurotoxicity at 540 ppm. Absolute testes weights were unchanged although relative testes weights in the highest dose group at 540 ppm were increased. Since the terminal bodyweights were reduced in this group about 8.6%, this change is considered to be a direct effect of growth retardation and not a true biological effect on the organ. Macroscopically there were two males in the high dose with reddened testes, seminal vesicles appeared normal. Histopathology of testes revealed no lesions in 18 of 20 animals, one animal with bilateral interstitial oedema and one with interstitial congestion in the high dose. Seminal vesicles were unremarkable in all treated animals. 4 females showed small cysts of no specific kind in ovaries at the highest dose. No other organs showed treatment-related macroscopic or microscopic effects. Based on this study alpha-cypermethrin did not induce substance-related endocrine effects at any dose.

A 90-day feeding study in rats ([redacted] 1994; SBTR.93.050; DocID: AL-425-007, see CA 5.7/6)

Alphacypermethrin was administered to groups of 15 male and 15 female Crd:CD (Sprague Dawley) BR rats for 90 days at dietary concentrations of 50, 250 and 500 ppm. The NOAEL was 50 ppm, based on decreased body weights and changes in hematology and clinical chemistry at 250 ppm. Absolute testes weights were unchanged although relative testes weights in the highest dose group were increased. Since the terminal bodyweights were reduced in this group (-8.8 %), the changes in relative weights of the testes were considered to reflect the bodyweight changes. This was supported by the microscopic investigations on epididymides, prostate, seminal vesicles and testes, which did not reveal substance-related effects at any dose. Furthermore, no substance related effects were seen in adrenals, thyroid, or female sex organs (ovaries and uterus). Based on this study alpha-cypermethrin did not induce substance-related endocrine effects at any dose.

2 year feeding study of WL43467 in rats ([redacted] 978; TLGR.0189.78; DocID CY-427-001 / addenda: [redacted] 1979; DocID CY-427-002 / [redacted] 1981; DocID CY-427-003 / [redacted] 1985; DocID CY-427-004 see CA 5.5)

This study was performed with Cypermethrin which contains approximately 25% alpha-cypermethrin. The rat cancer study has been used worldwide to fulfil the regulatory requirement for a cancer study in a second rodent species.

Several different groups of male and female Wistar rats received dietary concentrations of 1, 10, 100, and 1000 ppm Cypermethrin. A control group of 48 animals per sex received untreated diet. Groups of rats were scheduled for necropsy after 6 months (6/sex treated, 12/sex control), 12 months (6/sex treated, 12/sex control), 18 months (12/sex treated, 24/sex control) and 2 years (24/sex treated, 48/sex control) of treatment. No significant differences in survival were seen between treatment and control groups. There were no treatment-related effects on hematology, clinical chemistry and organ weights. Absolute testes weights were reduced in the 6 month interim high dose group but not in the 12, 18 or 24 month male rats, and without histological evidence of damage, the effect is not considered to be of toxicological significance. Macroscopic and histopathological examination did not indicate any toxicologically significant lesions in any organ or other effects that were considered related to treatment. The NOAEL was 100 ppm, based on decreased body weights in both sexes at 1000 ppm. No substance-related endocrine effects were observed at any dose.

Oral (gavage) rat developmental toxicity (teratogenicity) study [redacted] 1994; SLN/2/92; DocID: AL-432-002 see CA 5.6)

The effects of Alphacypermethrin on the pregnancy and embryonic or fetal development of the rat were investigated at 0, 3, 9, 18/15 and 15 mg/kg/day administered in corn oil by gavage from day 6 to day 15 post mating. Administration of Alphacypermethrin via gavage at 15 or 18 mg/kg/day to pregnant rats during fetal organogenesis elicited maternal toxicity characterized by changes in clinical conditions and reduction in food consumption and body weight gain during the dosing period. Further, a slight reduction in fetal weights was observed at these dose levels and was attributed to the observed maternal toxicity. The NOAEL for maternal toxic effects was 9 mg/kg/day, based upon clinical signs and reduced body weights at 15 mg/kg/day. The NOAEL for embryotoxic effects was also 9 mg/kg/day, based upon reduced fetal weights at 15 mg/kg/day. No substance-related endocrine effects were observed at any dose.

Toxicity studies on the insecticide WL 43467 (Cypermethrin): A three generation reproduction study in rats [redacted] 1978; TLGR.0188.78; DocID CY-430-001, and addenda [redacted] 1979; DocID CY-430-002 / [redacted] 1979; DocID CY-430-003 / [redacted] 1979; DocID CY-430-004 / [redacted] 1985; DocID CY-430-005)

This study was performed with Cypermethrin, which contains approximately 25% Alphacypermethrin. The rat reproduction and development study with Cypermethrin has been used worldwide to fulfil the regulatory requirement for a multi-generation fertility and development study for Alphacypermethrin.

Groups of approximately 30 Wistar rats per sex in each generation received Cypermethrin at dietary concentrations of 0, 10, 100, or 500 ppm throughout the entire experimental period up to weaning of F3 litters (pre-mating, mating, gestation and rearing). Two litters were produced from each parental generation.

Significantly reduced body weights and food consumption were observed in males and females of the parental generation at the 500 ppm level prior to mating. Minor reproductive effects were recorded at 500 ppm, comprising lower litter sizes and weights and lower pup weights, mainly for the F0-generation. At 10 and 100 ppm, no treatment-related effects on parents or litters at any generation were observed.

Macroscopic and microscopic investigations were performed on ovaries, testes and prostate/uterus, thyroid and parathyroid, pituitary, and adrenals of rats of F0, F1 and F2 parents as well as on F3B weanlings. No compound-related gross or microscopic pathological findings were observed. Especially the endocrine organs of the F3B generation at 500 ppm showed no abnormality in all examined pups. The NOAEL for parental animals was 100 ppm, based upon reduced food intake and body weight at 500 ppm during the pre-mating period. The NOAEL for reproduction and developmental effects was also 100 ppm, based upon reduced litter size at birth and reduced mean pup weights on day 21 for F1b females and F3B males. No substance-related endocrine effects were observed at any dose.

MICE studies (see Table Table 5.8.3-3)

Alphacypermethrin: preliminary toxicity study by dietary administration to CD-1 mice for four weeks [redacted] 1993; Report No.: 92/0346; DocID: AL-420-005) see CA 5.3

Groups of eight male and eight female CD-1 mice received Alphacypermethrin via the diet, at concentrations of 200, 400, 800, 1200, or 1600 ppm for 29 days. The NOAEL was 400 ppm, based on reduced body weight gains in females and reduced terminal body weight in males and females receiving 800 ppm. Absolute and relative weights of adrenal, testes or uterus were unchanged up to the highest dose of 1600 ppm. Macroscopic or microscopic evaluations on endocrine organs were not performed.

Alphacypermethrin preliminary toxicity study by dietary administration to CD-1 mice for 13 weeks [redacted] 1984; Report No.: 92/SHL009/0849; DocID: AL-425-006) see CA 5.3

Alphacypermethrin was fed to groups of 12 male and 12 female CD-1 mice at dietary concentrations of 50, 250, or 1000 ppm in the diet. The NOAEL was 50 ppm, based on decreased body weight gains, skin crusts, and increased aspartate aminotransferase activity at 250 ppm. At 1000 ppm relative testes weights were increased about 28 %, whereas the abs. weight was unaffected, suggesting this reflects bodyweight reduction (-23%). Other endocrine organs as adrenals and uterus were unaffected. Macroscopic and microscopic evaluations on adrenals, epididymides, ovaries, pituitary, prostate, testes, thyroid with parathyroid, and uterus revealed no substance-related endocrine effects.

Alphacypermethrin: Oncogenicity study by dietary administration to CD1 mice ([redacted] 1996; Report No.: 95/SHL010/0596; DocID AL-428-002, and amendment: [redacted] 1999; DocID AL-428-003) see CA 5.5

Groups of 72 male and 72 female CD-1 mice received diets containing 0, 30, 100, and 300 ppm of Alphacypermethrin. Interim sacrifices of 20 males and 20 females of each group were made after 52 weeks. The remainder of the animals were sacrificed after 78 weeks of treatment. The NOAEL was 30 ppm, based on decreased body weight and changes in appearance (ungroomed coats). Rel. adrenals weights in the interim group males showed some increase which was based on missing effect on absolute weights and without histopathological findings considered to reflect body weight changes. No inter-group differences in organ weights for absolute and relative testes were noted. Macroscopic and microscopic evaluations were performed on adrenals, epididymides, ovaries, pituitary, prostate, seminal vesicles, testes, thyroid, uterus and vagina. . There were no macroscopic changes in animals killed after 52 and 78 weeks of treatment which were considered to be related to treatment. No treatment-related neoplastic or non-neoplastic findings were observed during histopathological examination. Therefore, no substance-related endocrine effects were observed at any dose.

DOG studies

13 week oral dietary toxicity study in dogs ([redacted] 1984; Report No.: 3197; DocID: AL-425-005) see CA 5.3

Groups of 4 male and 4 female Beagle dogs received diets containing 0, 30 and 90 ppm of Alphacypermethrin while a fourth group comprised of 6 males and 6 females received 270 ppm test substance for up to 13 weeks. The NOAEL was 90 ppm, based upon clinical signs of neurotoxicity at 270 ppm. Organ weights were taken for adrenals, ovaries, pituitary, prostate/uterus, testes and thyroids. Histopathological examination of the listed tissues was undertaken for all the animals on the study and did not reveal any changes attritubed to alpha-cypermethrin. Lesions recorded like for example immature testes were considered to fall within the range of background pathology commonly seen in 6-12 month old Beagle dogs. It was concluded, that no substance-related endocrine effects were observed at any dose.

52 week oral (dietary) toxicity study in dogs ([redacted] 1995; Report No.: 11110; DocID: AL-427-001) see CA 5.3

Groups of 4 male and 4 female Beagle dogs were dosed orally via the diet, 7 days/week, for 52 consecutive weeks at concentrations of 0, 60, 120, or 240 ppm Alphacypermethrin. The NOAEL was 60 ppm, based on clinical signs of skin irritation in one female receiving 120 ppm Alphacypermethrin. Organ weights were taken for adrenals, ovaries, pituitary, prostate/uterus, testes and epididymides and thyroids with parathyroids. Histopathological examination of the listed tissues was undertaken for all the animals on the study. An incidental change was high uterus weights in females receiving 120 pppm. following absolute ($P<0.05$) and covariance analysis ($P< 0.001$). However, no dose-response relationship was evident. Moreover, because dogs may be in different stages of oestrus at the time of sacrifice, uterine weights may show normal biological variation. No substance-related endocrine effects were observed at any dose.

Literature data

Several publications with cypermethrin, beta-cypermethrin and alpha-cypermethrin and their common metabolites are related to endocrine effects and are discussed in the following. Based on the fact that alpha-cypermethrin is more related to beta-cypermethrin than cypermethrin, the literature focused on studies with beta-cypermethrin and publications with a potential to give insight into the Mode of action. Findings for common metabolites are discussed in this chapter as well, however the overall evaluation of metabolites is done in chapter CA 5.8.1.

The literature data are splitted up in the following sub-sections and in case of literature data dealing with different test systems the literature is placed in each section to inform about the outcome of the respective investigations. Whereever a study is splitted up it is indicated by a header that cross-references to the first citation.

- Androgen receptor assays *in vitro*
- Oestrogen receptor assays in vitro
- Aromatase and steroidogenesis assays in vitro
- Thyroid receptor assays in vitro

Each single chapter ends with a summary.

Androgen receptor assays *in vitro*

Report: CA 5.8.3/1
Kojima H. et al., 2004a
Screening for estrogen and androgen receptor activities in 200 pesticides by in vitro reporter gene assays using Chinese hamster ovary cells
2004/1040394
Guidelines: none
GLP: no

The authors tested a large number of pesticides for agonist and antagonist activity against the human oestrogen receptors α- and β- and the human androgen receptor in stably transfected CHO cells. The authors report that there was no evidence of androgenic or anti-androgenic activity for cypermethrin.

Classification of study: supplemental information

Report: CA 5.8.3/2
Tyler C.R. et al., 1999a
Metabolism and environmental degradation of pyrethroid insecticides produce compounds with endocrine activities
2000/1024078
Guidelines: none
GLP: no

The authors investigate interaction with the human androgen receptors in yeast cell reporter gene assays using a series of pyrethroids (including cypermethrin 'mixed isomers', 95.8% pure) and the common pyrethroid degradation products including M310I024, M310I011 as well as M310I001. Results were compared to the reference compounds 4-OH-tamoxifen and flutamide. Anti-oestrogenic and anti-androgenic effects were measured through co-incubation with 17β-oestrodiol or DHT, respectively. Cypermethrin showed no androgenic activity (very weak androgen activity is noted only at very high concentrations), but did show some evidence of weak anti-androgenic activity at high concentrations (LOEC = 10^{-3} M). The common metabolites M310I024 (PBAlc) was not active as androgen receptor agonist in yeast, but showed some anti-androgenic potential in the µ-molar range. M310I011 (PBA) and M310I001 (DCVA) showed neither androgenic nor anti-androgenic activity in yeast cells.

Classification of study: supplemental information

Report: CA 5.8.3/3
Vinggaard A.M. et al., 2007a
Screening of 397 chemicals and development of a quantitative structure - Activity relationship model for androgen receptor antagonism
2008/1102136
Guidelines: none
GLP: no

As part of a large screening study, the anti-androgenic activity of cypermethrin (no purity given) was investigated in a transfected CHO-K1 cell line reporter gene assay. Cells were exposed for 20 hours to concentrations of 1, 3, 10 and 30 µM and results expressed as the IC25 relative to the response seen with 0.1 nM the androgen R1881 (set as 100%). Cypermethrin was considered to be 'positive' in this assay (i.e. it showed 25% inhibition of the response to 0.1 nM of R1881 at a non-cytotoxic concentration of ≤10 µM and was assigned to Category 5, the least potent of 5 categories, based on an IC25 value of between 3 and 10 µM.

Classification of study: supplemental information

Report: CA 5.8.3/4
Xu L.-C. et al., 2007a
Evaluation of androgen receptor transcriptional activities of some pesticides in vitro
2008/1102137
Guidelines: none
GLP: no

The authors investigated human androgen receptor transcriptional activation in the stably-transfected monkey CV-1 cell line for a number of pesticides, including cypermethrin (>98% pure). Anti-androgenic activity was also investigated using the reference compound DHT. Cypermethrin is reported to have no androgenic activity and only weak anti-androgenic activity; activity was reported at all of the concentrations investigated (10^{-7}, 10^{-6}, 10^{-5} M) and the IC50 is reported to be 6.8 x10^{-5} M.

Classification of study: supplemental information

Report: CA 5.8.3/5
Zhang J. et al., 2008a
The antiandrogenic activity of pyrethroid pesticides Cyfluthrin and beta-Cyfluthrin
2008/1102138
Guidelines: none
GLP: no

Zhang *et al* investigated the anti-androgenic activity of cyfluthrin and beta-cyfluthrin (no purities given) *in vitro* and *in vivo*; comparison is also made to cypermethrin and beta-cypermethrin. *In vitro* anti-androgenic activity was assessed using a transcriptional activity assay in the stably transfected MDA-kb2 cell line and the reference compound DHT. In vivo anti-androgenic activity was investigated in the Hershberger assay with Testosterone propionate as androgen. Anti-androgenic activity is reported for cypermethrin but not for beta-cypermethrin at the single concentration investigated of 10^{-5} M in vitro. Weak anti-androgen activity was also found in vivo for Cypermethrin at 50 mg/kg bw, but not for beta-cypermethrin.

Classification of study: supplemental information

Report: CA 5.8.3/6
Wu W. et al., 2008a
Antiandrogenic effects of Cypermethrin and beta-Cypermethrin
2008/1102139
Guidelines: none
GLP: no

The anti-androgenic properties of cypermethrin and beta-cypermethrin (no purities given) were investigated *in vivo* in castrated male SD rats using a Hershberger assay using cypermethrin dose levels of 7, 21 or 63 mg/kg bw/d and beta-cypermethrin dose levels of 6, 18 and 54 mg/kg bw/d. In vitro the substances were investigated in a transcriptional activation assay based on MDA-kb2 cells at concentrations from 10^{-5} – 10^{-8} mol/L. Cypermethrin showed anti-androgenic activity *in vitro* at concentrations of 10^{-6} and 10^{-5} M; no effects were seen with beta-cypermethrin at any concentration. *In vivo*, administration of cypermethrin was shown to affect androgen-dependent organ weight at the mid- and high dose level groups. No effects were seen with beta-cypermethrin. The authors therefore conclude that cypermethrin is a weak anti-androgen *in vitro* and *in vivo*, but that beta-cypermethrin showed no such activity.

Report: CA 5.8.3/7
Du G. e al., 2010a
Assessing hormone receptor activities of pyrethroid insecticides and their metabolites in reporter gene assays
2010/1232195
Guidelines: none
GLP: no

Cypermethrin (purity: 92%) and its metabolites M310I011 (99% pure) and DCVA (99% pure) were assessed for activity in androgen receptor (stably transfected MDA-kb2 cells) reporter gene assays at non-cytotoxic concentrations of between 10^{-9} M and 10^{-5} M. There was no evidence of any androgenic activity. M310I011 showed slight (but not significant) anti-androgenic activity (RIC_{20} >10^{-5} M); DCVA did not show any anti-androgenic activity; cypermethrin showed significant anti-androgenic activity at concentrations of 10^{-6} and 10^{-5} M (RIC_{20} =1.64 x10^{-6} M).

Report: CA 5.8.3/8
Sun H. et al., 2006a
Antiandrogenic activity of Pyrethroid pesticides and their metabolite in reporter gene assay
2007/1070385
Guidelines: none
GLP: no

The androgenic and anti-androgenic effects of cypermethrin (>99% pure) and the pyrethroid metabolite M310I011 (>99% pure) were investigated in a human androgen receptor mediated reporter gene assay using the CV-1 cell line. Cells were exposed to non-cytotoxic concentrations of cypermethrin or M310I011 of 10^{-11} to 10^{-5} M in the absence or presence of DHT for 24 hours. No evidence of androgenic activity was seen in this study; however both cypermethrin and M310I011 showed anti-androgenic activity (i.e. inhibition of the response to DHT). IC_{20} values of 0.42 mM and 1.21 mM are reported for cypermethrin and M310I011, respectively. The authors conclude that cypermethrin and M310I011 show comparable anti-androgenic activity in this assay.

Classification of study: supplemental information

Report: CA 5.8.3/9
Tange S. et al., 2014a
In vitro metabolism of cis- and trans-Permethrin by rat liver microsomes, and its effect on estrogenic and anti-androgenic activities
2014/1242695
Guidelines: none
GLP: no

The authors report that permethrin showed weak anti-androgenic activity (IC20 =51.73 µM) in transfected CHO cells. Trans-permethrin showed stronger anti-androgen activity (IC20 =8.58µM). Cis-permethrin showed a comparably weak anti-androgenic activity (IC20 =21.91 µM). Incubation with liver microsomal fraction enhanced the anti-androgenic activity of permethrin and trans-permethrin, but did not have an effect on cis-permethrin. Following incubation with liver microsomal fraction, the metabolites of trans-permethrin were identified as phenoxybenzoic alcohol (M310I024) (quantitatively most important), phenoxybenzoic aldehyde (M301I018), phenoxybenzoic acid (M310I011) and 4-OH phenoxybenzoic alcohol. The metabolism of cis-permethrin was much less extensive; however the additional metabolite 4-OH cis-permethrin was identified. Incubation of permethrin showed intermediate results, indicating that the majority of metabolites originated from the *trans*-isomers. Of the metabolites, M310I024 (98% pure) showed greater anti-androgenic activity (IC_{20} =1.15 µM). M310I018 (97% pure) showed the strongest anti-androgenic activity (IC_{20} =0.17 µM). M310I011 (98% pure) showed no anti-androgenic activity. 4-OH *cis*-permethrin showed comparable anti-androgenic activity to *cis*-permethrin (IC_{20} =23.83 µM). 4-OH phenoxybenzoic alcohol (>99% pure) showed no anti-androgenic activity. 4-OH phenoxybenzoic acid (M310I025; >98% pure) showed no anti-androgenic activity. 2-OH phenoxybenzoic alcohol (>98% pure) showed anti-androgenic activity (IC_{20} =4.89 µM). 2-OH phenoxybenxoic acid showed no anti-androgenic activity.

Summary of responses and effects of metabolism (Tange *et al*, 2014)

	Anti-androgenic activity IC_{20} (µM)	Effect of metabolism on activity
Permethrin	51.73	↑
cis-permethrin	21.91	-
trans-permethrin	8.58	↑
M310I024	1.15	
M310I018	0.17	
M310I011	-	
4-OH *cis*-permethrin	23.83	
4-OH phenoxybenzoic alcohol		
4-OH phenoxybenzoic acid (M310I025)	-	
2-OH phenoxybenzoic alcohol	4.89	
2-OH phenoxybenzoic acid	-	

The authors conclude that the metabolism of permethrin and trans-permethrin results in increased anti-androgenic activity; however no effect is seen with *cis*-permethrin. This finding is notable with regard to alpha-cypermethrin, which consists only of *cis*-isomers of cypermethrin.

Classification of study: supplemental information

Report: CA 5.8.3/10
Kjeldsen L.S. et al., 2013a
Currently used pesticides and their mixtures affect the function of sex hormone receptors and aromatase enzyme activity
2013/1417281
Guidelines: none
GLP: no

Several test compounds, including Cypermethrin (>95% pure) were tested on their androgenic/anti-androgenic potential in a transactivation assay in the concentration range of 10^{-10} to 10^{-5} M. The androgen receptor transactivation assay was performed in CHO-K1 cells that were transiently co-transfected with the MMTV-LUC reporter vector and the human AR expression plasmid pSVARO. The authors reported that cypermethrin showed no androgenic effects, but showed a slight tendency to antagonize the R1881- or DHT-induced (25 pM) androgen receptor transactivity at the highest test concentration, although not statistically significant.

Classification of study: supplemental information

Report: CA 5.8.3/11
Ait-Aissa S. et al., 2010a
Anti-androgenic activities of environmental pesticides in the MDA-kb2 reporter cell line
2010/1232202
Guidelines: none
GLP: no

Several test compounds, including cypermethrin (no purity given) were tested on their androgenic/anti-androgenic potential in a transactivation assay. The androgen receptor transactivation assay was performed in MDA-kb2 cells that were stably transfected with the MMTV-LUC reporter vector. In these cells this promoter is up-regulated by two endogenous nuclear receptors, AR and GR. Cypermethrin was tested in the range of 0.01 to 10 µM in solvent alone (DMSO) or in the presence of 0.1 nM DHT for the determination of androgenic or anti-androgenic effects, respectively. Cypermethrin was not cytotoxic up to concentrations of 10 µM. No androgenic or anti-androgenic effect was reported for cypermethrin in the applied in vitro model using MDA-kb2 cells.

Classification of study: supplemental information

Overview of androgen receptor assays

Available assays are relatively consistent in identifying cypermethrin as a weak anti-androgen at relatively high concentrations which may not be of direct relevance to the human risk assessment. Similar activity is not reported for beta-cypermethrin, indicating that the activity is associated with specific isomers. There is no evidence of any androgenic activity, neither for cypermethrin nor beta-cypermethrin.

No androgenic activity was found in any test system for the common metabolites M310I011, M310I018, M310I024, M310I001 and for the 4-hydroxylated PBA metabolite M310I025.

Anti-androgenic activity was reported for M310I024 (IC_{20}=1.15µM) and even stronger for M310I018 (IC_{20}=0.17 µM), but no relevant activity was found for the most dominant metabolite M310I011 (reported activity in the millimolar range not considered of any relevance) or its in position 4 hydroxylated derivative M310I025 nor for M310I001.

The US EPA assessment cautions that none of the studies directly assesses binding to the androgen receptor. In general, transcriptional activation assays and receptor binding assays are both needed to increase the level of confidence and minimise the potential for false negative responses. Transcriptional activation assays do not measure receptor binding and involve post-binding events; therefore, they are not a direct substitute for receptor binding assays. Additional mechanistic studies (summarised below) indicate that the anti-androgenic effects of cypermethrin are not due to a direct interaction with the receptor.

The differences in response reported for cypermethrin and beta-cypermethrin is notable and indicates that the anti-androgenic effects of cypermethrin (8 isomers, for isomeric composition of cypermethrins see Document N5, Bridging rational) are associated with specific isomers. The absence of anti-androgenic effects for beta-cypermethrin (4 isomers of cypermethrin, cis-2 and trans-4) would indicate a similar lack of effects for alpha-cypermethrin (2 isomers of beta-cypermethrin, only cis-2). The study of Tange *et al* (2014) performed with permethrin, *cis*-permethrin and *trans*-permethrin shows greater anti-androgenic activity with *trans*-permethrin compared to permethrin and *cis*-permethrin; and furthermore shows an increase in anti-androgenic potential following the metabolism of permethrin and *trans*-permethrin but not following the metabolism of *cis*-permethrin. This effect is attributable to the much less extensive metabolism of the *cis*-isomers and an apparent association of anti-androgenic activity with permethrin metabolites common to other pyrethroids. These observations are pertinent for cypermethrin and alpha-cypermethrin due to the common metabolites and the fact that alpha-cypermethrin consists solely of *cis*-isomers. The difference in response between cypermethrin and beta-cypermethrin may be explained by the lower proportion of *trans*-isomers in beta-cypermethrin.

Therefore it is concluded that weight of evidence indicate that alpha-cypermethrin is not at risk to be androgenic and as well is not at risk to be anti-androgenic or to induce anti-androgenic response via metabolic degradation. This is in line with in vivo findings.

Oestrogen receptor assays *in vitro*

Kojima *et al* (2004) see CA 5.8.3/1 2004/1040394
Screening for Estrogen and Androgen Receptor Activities in 200 Pesticides by *In Vitro* Reporter Gene Assays Using Chinese Hamster Ovary Cells
Environmental Health Perspectives 112(5):524-531

The authors tested a large number of pesticides for agonist and antagonist activity against human oestrogen α- and β- receptors in stably transfected CHO-K1 cells. Cypermethrin (>95% pure) was tested at concentrations between 10^{-8} M to 10^{-5} M and is reported to show activity in the ER-α transactivation assay (REC20 =8.1 x10^{-6} M). The US EPA considers that this study does not provide sufficient information to permit independent review; specifically, the absence of solubility and cytotoxicity data are cited as limiting factors.

Metabolism and environmental degradation of pyrethroid insecticides produce compounds with endocrine activities
Environmental Toxicology & Chemistry 19(4):801-809

The authors investigated interaction with the human oestrogen receptor in a yeast cell reporter gene assay using a series of pyrethroids (including cypermethrin) and the common pyrethroid degradation products M310I024 and M310I011. Results were compared to the reference compound 4-OH-tamoxifen. Anti-oestrogenic effects were measured through co-incubation with 17β-oestrodiol. Cypermethrin (95.8% pure) is stated to have showed no oestrogenic activity (data not shown) but is, however, reported to have anti-oestrogenic activity (LOIC = 7±3 x10^{-4} M), 1000-10000 times less potent than 4-OH-tamoxifen. Of the seven pyrethroids tested, four pyrethroids showed anti-oestrogenic activity; cypermethrin was the least potent. The pyrethroid metabolite 3-phenoxybenzylalcohol showed weak oestrogenic activity (10^5 times less potent than 17β-oestrodiol). The metabolite M310I011 also showed anti-oestrogenic activity (10^2-10^3 times less potent than 4-OH-tamoxifen). The authors conclude that the hormone receptor interaction seen in this assay with various pyrethroids may in fact be due to their metabolites, which are stated to be generated by yeast esterase activity.

Assessing Hormone Receptor Activities of Pyrethroid Insecticides and Their Metabolites in Reporter Gene Assays
Toxicological Sciences 116(1):58-66

Cypermethrin (92% pure) and its metabolites M310I011 (3-PBA, 99% pure) and DCCA (99% pure) were assessed for activity in oestrogen receptor transfected CV-1 cells using a reporter gene assay at non-cytotoxic concentrations of between 10^{-9} M and 10^{-5} M. There was no evidence of any oestrogenic activity for any substance investigated. 3-PBA showed significant anti-oestrogenic activity at concentrations of 10^{-6} and 10^{-5} M (RIC_{20} =8.84 x10^{-8} M); DCCA showed significant anti-oestrogenic activity at concentrations of ≥10^{-8} M (RIC_{20} =7.23 x10^{-9} M); cypermethrin did not show any anti-oestrogenic activity.

Estrogenicity of organophosphorus and pyrethroid pesticides
2002/1027197
Guidelines: none
GLP: no

The authors investigated the oestrogenic activity of a number of pesticides, including cypermethrin (>90% pure), in three *in vitro* screening assays. A competitive binding assay with ^{3}H-oestradiol was performed using rat uterine cytosolic oestrogen receptors at concentrations between 10^{-12} and 10^{-6} M. Oestrogen receptor activation was assessed using the E-screen (induction of proliferation of oestrogen-sensitive MCF-7 cells) at concentrations between 10^{-11} and 10^{-6} M. Transcriptional activation of the oestrogen receptor was also measured using a pS2 mRNA assay in the MCF-7 cell line at concentrations between 10^{-10} and 10^{-6} M. The MCF-7 assay (E-screen) showed cypermethrin (purity: >90%) -induced proliferation; values were statistically significant compared to controls at a concentration of 10^{-8} M only and not at higher concentrations. The maximum fold proliferation is reported to be relatively low (1.46 at 10^{-8} M). The proliferation induced by cypermethrin was blocked by co-incubation with the oestrogen receptor antagonist ICI 182 780, leading to the authors' conclusion that cypermethrin acts as a partial oestrogen receptor agonist. Cypermethrin was also shown to competitively inhibit the binding of ^{3}H-oestradiol to rat uterine cytosolic oestrogen receptors at the higher concentrations tested (≥10^{-6} M); an IC_{50} of 0.562 mM was calculated. The maximum level of inhibition was approximately 50% and the relative potency was about 500,000 times lower than oestradiol. Expression of pS2 mRNA in MCF-7 cells was also significantly increased (2.01-fold) following incubation with cypermethrin at the highest investigated concentration of 10^{-6} M. The US EPA assessment considers that this study satisfies the requirement for an oestrogen receptor binding assay.

Kim I.Y. et al., 2003a
Assessing estrogenic activity of pyrethroid insecticides using in vitro combination assays
2004/1040395
Guidelines: none
GLP: no

The authors investigated the oestrogenicity/anti-oestrogenicity of several pyrethroids, amongst them cypermethrin (98% pure) *in vitro* in MCF-7 BUS cells (E-screen). Oestrogen receptor levels and PS2 mRNA levels were also assessed. A competitive binding assay (with 3H-oestradiol) was performed using ovariectomised rat uterine cytosol.
No oestrogenic-like effect of cypermethrin (10^{-5} M) was seen following treatment for 6 days in the E-Screen assay. There was no evidence of cytotoxicity. No anti-oestrogenic effect was seen with 10^{-6} M cypermethrin in MCF-7 cells simultaneously exposed to ICI 182 780. No evidence for the inhibition of binding for ^{3}H-oestradiol to the oestrogen receptor was seen in uterine cytosol prepared from ovariectomised rats. Oestrogen receptor levels and PS2 mRNA levels were not assessed with cypermethrin in the absence of any indication of oestrogenic activity. This assay does not therefore provide any evidence for oestrogen receptor binding or activation for cypermethrin (in contrast to one of the other pesticides tested); however the reliability of the assay is limited by poor reporting. The USEPA assessment considers that the study is limited due to the absence of replicate data and the use of a single concentration.

Activation of alpha- and beta-estrogen receptors by persistent pesticides in reporter cell lines
2006/1051139
Guidelines: none
GLP: no

A range of pesticides (including cypermethrin, >95% pure) were screened for transcriptional activation of the oestrogen α- and β-receptors using the stably transfected HeLa cell line. Cypermethrin was tested at a single concentration of 10 µM. In the absence of any indication of a positive response in HeLa ERα or HeLa ERβ, further concentrations were not tested. US EPA raises concerns over the validity of this assay as only a single concentration was tested, increasing the likelihood of a false negative response.

A study on the estrogenic effects of alpha- and theta-Cypermethrin
2005/1043340
Guidelines: none
GLP: no

A positive result is reported for alpha-cypermethrin (at the single tested concentration of 10^{-8} M, purity not given) and theta-cypermethrin (at the single tested concentration of 10^{-8} M, purity not given) in the MCF-7 cell proliferation assay; the level of induced proliferation was greater for alpha-cypermethrin than for theta-cypermethrin, and was in fact greater than that induced by the positive control (10^{-8} M β-oestradiol). Some inhibition of proliferation was induced by the solvent control (0.1% ethanol). The results of this study therefore indicate oestrogenic activity for alpha-cypermethrin and theta-cypermethrin; however the level of response seen indicates that the study is of questionable reliability.

Jin M. et al., 2009a
Estrogenic activities of two synthetic pyrethroids and their metabolites
2010/1232199
Guidelines: none
GLP: no

The oestrogenic activity of cypermethrin (unclear substance: the abstract states that beta-cypermethrin was investigated, 98% pure), and its metabolites M310I011 (PBA, 98% pure), M310I024 (PBAlc, 98% pure) and M310I018 (PBAld, ≥97% pure) were investigated *in vitro* using the MCF-7 cell proliferation assay. Cells were exposed to cypermethrin or its metabolites at concentrations between 10^{-9} to 10^{-5} M for six days. Levels of pS2 (oestrogen-inducible) mRNA and ER-α mRNA were measured using PCR in cells exposed to 10^{-6} M for 2 days. Significantly increased cell proliferation was seen in cells exposed to cypermethrin at concentrations of 10^{-8}, 10^{-7} and 10^{-6} M, with a maximal effect (1.63 times controls) seen at 10^{-7} M. Significantly increased cell proliferation was seen following exposure to M310I011 at a concentration of 10^{-7} M only; however this effect was marginal (1.32 times controls). Significantly increased cell proliferation was seen in cells exposed to M310I024 at concentrations of 10^{-9}, 10^{-8}, 10^{-7} and 10^{-6} M, with a maximal effect (1.7 times controls) seen at 10^{-7} M – a relatively low concentration and only 10-100 times lower than reported for oestradiol. No significant effects on cell proliferation were seen at any concentration of M310I018. Increased expression of pS2 mRNA was seen in response to cypermethrin (2.15 times the control) and all metabolites; the greatest response was seen with M310I024 (3.45 times). A lower response was seen with cypermethrin and relatively weak responses were seen with M310I011 (1.85 times) and 3-phenoxybenzaldehyde (1.37 times). Reduced expression of ER-α mRNA was seen following exposure to cypermethrin and M310I024; a marginal effect was seen with M310I011 (-12.0%) and no effect was seen with M310I018 (PBAld) (-3.7%). The results of this study show oestrogenic activity *in vitro* with cypermethrin and indicate that this may be increased by initial metabolism to M310I024 but may also reduced by subsequent metabolism to the aldehyde and acid derivatives. A notable feature of this study is the production of non-linear dose-response curves for all of the substances investigated. The concentrations investigated do not indicate significant cytotoxicity and may therefore reflect a technical problem with the assay.

Report: CA 5.8.3/18
Wang Q. et al., 2011a
Estrogenicity activity assessment and mechanism exploration on Alpha-Cypermethrin in vitro
2011/1296734
Guidelines: none
GLP: no

The effects of alpha-cypermethrin (commercial grade, no purity given) were assessed in the MCF-7 cell line; cells were exposed to concentrations of 10^{-7}, 10^{-8} or 10^{-9} M for five days. Levels of ERα mRNA were also measured using PCR. A significant increase in cell proliferation was seen at all alpha-cypermethrin concentrations; the response was maximal (1.38 times the control value) at the highest concentration tested however the blank control value was also significantly higher (1.16 times the solvent control). Findings therefore indicate either solvent toxicity or that value for alpha-cypermethrin at concentrations of 10^{-8} M (response 1.13 times the solvent control) or 10^{-9} M (1.19 times the solvent control) is within the background range. Exposure to alpha-cypermethrinwas also shown to slightly up-regulate the relative expression of ERα mRNA at concentrations of 10^{-9} M (1.39 times the control response), 10^{-8} M (1.45 times) and at 10^{-7} M (1.61 times). Values for ERα mRNA expression are calculated using β-actin as an internal control according to the $2^{-\Delta\Delta Ct}$ method.

Tange *et al* (2014) see CA 5.8.3/9 2014/1242695
In vitro metabolism of cis- and trans-permethrin by rat liver microsomes and its effect on estrogenic and anti-androgenic activities
Environmental Toxicology & Pharmacology 37 (2014) 996-1005

The authors report that permethrin showed weak oestrogenic activity (EC_{20} =18.82 µM) in transfected MCF-7 cells. Trans-permethrin also showed weak oestrogenic activity (EC_{20} =25.10 µM). In contrast, cis-permethrin showed no oestrogenic activity. The incubation of permethrin with liver microsomal fraction enhanced the oestrogenic activity. A marked enhancement of oestrogenic activity was apparent for cis-permethrin, but no effect was seen with trans-permethrin. Following incubation with liver microsomal fraction, the metabolites of trans-permethrin were identified as phenoxybenzoic alcohol (quantitatively most important), phenoxybenzoic aldehyde, phenoxybenzoic acid and 4-OH phenoxybenzoic alcohol. The metabolism of cis-permethrin was much less extensive; however the additional metabolite 4-OH cis-permethrin was identified. Incubation of permethrin showed intermediate results, indicating that the majority of metabolites originated from the trans-isomers. Of the metabolites, phenoxybenzoic alcohol (98% pure) showed comparable oestrogenic activity (EC_{20} =19.97 µM) to permethrin. Phenoxybenzoic aldehyde (97% pure) showed no oestrogenic activity. Phenoxybenzoic acid (98% pure) showed no oestrogenic activity. 4-OH cis-permethrin showed oestrogenic activity (EC_{20} =10.77 µM), in contrast to cis-permethrin. 4-OH phenoxybenzoic alcohol (>99% pure) showed oestrogenic activity (EC_{20} =2.48 µM). 4-OH phenoxybenzoic acid (>98% pure) showed no oestrogenic activity. 2-OH phenoxybenzoic alcohol (>98% pure) showed no oestrogenic activity. 2-OH phenoxybenzoic acid showed no oestrogenic activity.

Summary of responses and effects of metabolism (Tange *et al*, 2014)

	Oestrogenic activity EC20 (µM)	Effect of metabolism on activity
Permethrin	18.82	↑
cis-permethrin	-	↑↑
trans-permethrin	25.10	-
Phenoxybenzoic alcohol (M310I024)	19.97	
Phenoxybenzoic aldehyde (M310I018)	-	
Phenoxybenzoic acid (M310I011)	-	
4-OH *cis*-permethrin	10.77	
4-OH phenoxybenzoic alcohol	2.48	
4-OH phenoxybenzoic arid (M310I025)	-	
2-OH phenoxybenzoic alcohol	-	
2-OH phenoxybenzoic acid	-	

The authors conclude that metabolism of permethrin results in enhanced oestrogenicity due to the production of 4-OH *cis*-permethrin, phenoxybenzoic alcohol and 4-OH phenoxybenzoic alcohol. Metabolism of *cis*-permethrin similarly results in enhanced oestrogenicity; however no effect is seen with *trans*-permethrin. No effect is seen with *cis*-permethrin; this finding is of relevance to alpha-cypermethrinas this consists of the *cis*-isomers only.

GLP: no

Cypermethrin (92% pure) and its metabolite M310I011 (3-PBA, 99% pure) were assessed for activity in human or rat estrogen receptor transfected CV-1 cells using a luciferase reporter assay. No cytotoxicity was observed up to 100 µM of the test substance concentrations as determined by MTT assay in former experiments, microscopic examination, and determination of expression of co-transfected Renilla luciferase in the actual experiments. Cypermethrin showed an estrogenic activity in both, the hER and rER assay. The maximum induction (%) was 26% and 34% in the hER and rER assay, when compared to 100 nM E2. EC_{50} values were 0.37 µM and 6.78 µM in the hER and rER assay, respectively. PBA showed no estrogenic activity up to concentrations of 100 µM in the hER and rER assays. No anti-estrogenic effects were observed for cypermethrin in both assays. PBA (100 µM) significantly reduced the activity of 1 nM E2 to 55% in the hER assay, indicating that PBA possesses an anti-estrogenic potential.

Classification of study: supplemental information

Overview of oestrogen receptor assays

The available assays are inconsistent for cypermethrin; reporting negative, weak positive and positive responses in oestrogen receptor binding and activation assays. The US EPA identify the study of Chen et al (2011) as meeting the requirement for an oestrogen receptor binding assay but do not consider the studies adequate to meet the requirement for an oestrogen receptor transcriptional activation assay.
For alpha-cypermethrin only two MCF-7 proliferation assays are published: Liang *et al*, 2005 reports a marked positive response but is of questionable reliability; a further study (Wang *et al*, 2011, same lab and same method than Liang et al, 2005) reports a weaker proliferative response, but the study is also of limited reliability. A potential induction of proliferation of MCF-7 cells is not directly attributable to an estrogenic effect; therefore the relevance of this information is questionable.
Studies with metabolites indicate that estrogenic effects of rather weak potency may be due to the metabolite M310I024 rather than due to the parent substance. For M310I018 only some estrogenic activity was reported on mRNA level or in yeast cells, but not in a transactivation assay in mammalian cells, and no relevant estrogenic activity was reported for M310I011 and M310I019, M310I001 or M310I025. Worth to mention are results from Tange *et al* (2014) reporting oestrogenic activity in vitro for permethrin and *trans*-permethrin, but not for *cis*-permethrin. Metabolic degradation is shown to increase the oestrogenic response to permethrin but not to *trans*-permethrin, and also results in a positive response for *cis*-permethrin. Data indicate that estrogenic findings of permethrin are mainly due to the metabolite 4-OH phenoxybenzoic alcohol and 4-OH *cis*-permethrin; however these metabolites are both not found in any in vivo metabolic pathway of alpha-cypermethrin nor in plants and are therefore not considered relevant in the endocrine evaluation of alpha-cypermethrin. However, the difference in the proliferative response of MCF-7 cells seen with cypermethrin (weak, inconsistent oestrogenicity) and with alpha-cypermethrin (only two studies but both reporting positive responses) may be attributable to the metabolism in vitro.
Furthermore, weak anti-estrogenic activity is reported for M310I001 and M310I011 in yeast cells and moderate activity in two transactivation assays, both in CV-1 cells. According to these studies M310I001 is slightly more potent than M310I011, which showed relevant anti-estrogenic activity at physiologically rather unrelevant higher µ-molar concentrations.

Weight of evidence for cypermethrin does not indicate estrogenic effects and are considered valid for alpha-cypermethrin, too. Observed proliferative effect induces by alpha-cypermethrin might be due to in vitro generated metabolites, however these metabolites are not conisered relevant in vivo. An estrogenic effect via M310I024 is considered not relevant based on the slow metabolic release and the further detoxification of this metabolite via Phase II conjugation.
Weight of evidence indicate no anti-estrogenic activity for cypermethrin and is considered valid for alpha-cypermethrin, too. Furthermore the weak anti-estrogenic effects observed for M310I001 and M310I011 are considered less relevant for alpha-cypermethrin based on the slow metabolic release and the further detoxification of this metabolites via Phase II conjugation.

RIE: Relative inhibitory efficiency is the ratio between the maximal down-regulation of Era expression level by the test compound to that of E2(x100), IC50: Concentration of 50% response inhibition.

Aromatase and steroidogenesis assays in vitro

Report: CA 5.8.3/22
Laville N. et al., 2006a
Modulation of aromatase activity and mRNA by various selected pesticides in the human choriocarcinoma JEG-3 cell line
2006/1051133
Guidelines: none
GLP: no

The effects of a number of pesticides including cypermethrin (no purity given) on aromatase were assessed in the human JEG-3 cell line (tritium release assay). No inhibition of aromatase activity was seen at a concentration of 10 µM cypermethrin. The authors report that cypermethrin increases aromatase activity; values are not reported, but from the graphical data induction of approximately 1.4x, 1.5x and 1.6x the control was seen at concentrations of 1, 3, and 10 µM, respectively. The induction of aromatase activity was seen at concentrations of ≥3 µM after exposure for 24 hours (but not following exposure for 2 hours), and attained statistical significance only at the highest concentration tested of 10 µM. A marginal increase in the expression of *cyp19* mRNA (1.4 times) was not statistically significant compared to controls. The authors conclude that cypermethrin induces aromatase activity but (based on the response seen only at 24 hours), consider that this is not through transcriptional activation. It is speculated that some effect of cypermethrin on post-transcriptional regulation may be involved. The US EPA have reservations about the reliability of this study but consider that this may be acceptable if replicate data are provided.

Report: CA 5.8.3/23
Morinaga H. et al., 2004a
A benzimidazole fungicide, Benomyl, and its metabolite, Carbendazim, induce aromatase activity in a human granulose-like tumor cell line (KGN)
2004/1040397
Guidelines: none
GLP: no

In this study, a number of pesticides and other chemicals were screened for effects on catalytic aromatase activity (assessed as the conversion of androstenedione to oestrone) using the steroidogenic KGN cell line, which exhibits a relatively high level of aromatase activity. The single concentration of 10^{-5} M cypermethrin (no purity given) investigated was shown to slightly (but significantly) inhibit aromatase activity relative to controls, following incubation for 30 hours. There was no concurrent assessment of cytotoxicity; however significant cytotoxicity is not reported at this concentration in other *in vitro* assays. Further investigations were not performed. The US EPA review raises concerns over the reliability of this study (potential for false negative or false positive results) due to the use of a single concentration.

Classification of study: supplemental information

Report: CA 5.8.3/24
Taxvig C. et al., 2013a
In vitro - in vivo correlations for endocrine activity of a mixture of currently used pesticides
2013/1416882
Guidelines: none
GLP: no

The authors investigated the effects of various pesticides including cypermethrin (no purity given), either individually or in various combinations in the *in vitro* H295R cell steroidogenesis assay (exposure for 48 hours at concentrations between 1.6-100 µM). Cypermethrin at concentrations of 3.13, 6.25 and 12.5 µM was found to significantly increase oestradiol production. No significant effects were seen at concentrations of 25 or 100 µM and a marginal (but statistically significant) reduction in oestradiol production was seen at 50 µM. Cypermethrin at concentrations of 6.25 and 12.5 µM was found to significantly increase progesterone production; no effects were seen at concentrations of ≥25 µM. No effects of cypermethrin at any concentration were seen on testosterone production. All cypermethrin concentrations are reported to be non-cytotoxic.

Aromatase inhibiting and combined estrogenic effects of parabens and estrogenic effects of other additives in cosmetics
Toxicology and Applied Pharmacology 230 (2008) 372-382

Several test compounds, including M310I019 (3-hydroxy benzoic acid; no purity given) were tested on their effect on aromatase activity in vitro with microsomes from human placenta samples. M310I019 was tested in triplicates in 24-well plates in the range of 100 nM to 100 µM. For determination of aromatase activity 15 µg protein in 250 µL final volume was used together with 1β-^{3}H-androstenedion (357 nM). The authors reported that none of the hydroxylated benzoic acid isomers did inhibit aromatase statistically significant. In conclusion, M310I019 did not inhibit aromatase activity in microsomes derived from human placental tissue.

Classification of study: supplemental information

Overview of aromatase and steroidogenesis assays

Laville *et al* (2006) note the discrepancy between the results of their study with cypermethrin which reported weak aromatase induction and the study of Morinaga et al (2004) which reports weak aromatase inhibition with cypermethrin. The authors speculate that this discrepancy may be due to different regulation of aromatase expression between different cell types. Taxvig *et al* (2013) report a significant increase in the production of oestradiol in H295R cells exposed to cypermethrin, which is consistent with the findings of Laville *et al* (2006); however findings are inconsistent and only apparent at intermediate concentrations. The authors also report increased progesterone production at intermediate concentrations. Based on the results of these studies, there is no convincing evidence for an effect of cypermethrin on aromatase activity or steroidogenesis. No aromatase inhibiting effect was reported for the metabolite M310I019.

Table 5.8.3-6: Summary of aromatase and steroidogenesis assays

Study	Finding	Comment
Laville *et al* (2006)	Weak aromatase induction by cypermetrhrin	Response may be due to post-transcriptional regulation
Morinaga *et al* (2004)	Weak aromatase inhibition by cypermethrin	Single concentration assessed
Taxvig *et al* (2013)	Inconsistent effect on steroidogenesis	Increased oestradiol and progesterone synthesis seen at intermediate concentrations
van Meeuwen *et al* (2008)	Negative for M310I019	No aromatase-inhibiting effect reported for 3-hydroxy benzoic acid

Thyroid receptor assays in vitro

Du *et al* (2010) see CA 5.8.3/7 2010/1232195
Assessing Hormone Receptor Activities of Pyrethroid Insecticides and Their Metabolites in Reporter Gene Assays
Toxicological Sciences 116(1):58-66

Cypermethrin (92% pure) and its metabolites M310I011 (99% pure) and M310I001 (in report: DCCA; 99% pure) were assessed for activity in thyroid hormone receptor (stably transfected CV-1 cells) reporter gene assays at non-cytotoxic concentrations of between 10-9 M and 10-5 M. For agonistic activity tests, the CV-1 cells were exposed to various concentrations of tested chemicals, various concentrations of T3 (10-11 to 10-6 M) (positive control), or 0.1% DMSO (negative control). Cypermethrin showed significant but only slight antagonistic activity just reaching the relative inhibitory concentration of 20% to control at 10-5 µM (RIC20= 8.31 x10-6 M) and M310I011 showed a similar antagonistic activity without significance. M310I001 did not show any activity.

Classification of study: supplemental information

Overview of Thyroid receptor assays

Du *et al* [see CA 5.8.3/7 2010/1232195] investigated the potential of Cypermethrin, 3-PBA and DCCA to suppress T3-binding to the thyroid receptor. Among the investigated pyrethroids, cypermethrin and its metabolite were the least potent antagonists, which hardly or even barely reached RIC20 levels at 10^{-5}M. DCCA showed no activity.

Based on the results of this study, showing no agonistic and only weak antagonistic effects in the 10 µM dose range for cypermethrin, and less activity for the metabolites M310I011 and M310I001, the impact is considered of rather minor relevance for the human risk assessment of alpha-cypermethrin.

Investigations with Cypermethrin

Rat - Hershberger assays

Wu *et al* (2008) see CA 5.8.3/6 2008/1102139
Anti-androgenic properties of cypermethrin and β-cypermethrin
Chinese journal of industrial hygiene and occupational diseases 26(4)

The anti-androgenic properties of cypermethrin (no purity given) and beta-cypermethrin (no purity given) were investigated *in vivo* in castrated male SD rats using a Hershberger assay using cypermethrin dose levels of 7, 21 or 63 mg/kg bw/d and beta-cypermethrin dose levels of 6, 18 and 54 mg/kg bw/d. In vitro the substances were investigated in a transcriptional activation assay based on MDA-kb2 cells at concentrations from 10^{-5} – 10^{-8} mol/L. Cypermethrin showed anti-androgenic activity *in vitro* at concentrations of 10^{-6} and 10^{-5} M; no effects were seen with beta-cypermethrin at any concentration. *In vivo*, administration of cypermethrin was shown to affect androgen-dependent organ weight at the mid- and high dose level groups. No effects were seen with beta-cypermethrin. The authors therefore conclude that cypermethrin is a weak anti-androgen *in vitro* and *in vivo*, but that beta-cypermethrin showed no such activity.

Classification of study: supplemental information

Zhang *et al* (2008) see CA 5.8.3/5 2008/1102138
The antiandrogenic activity of pyrethroid pesticides cyfluthrin and β-cyfluthrin
Reproductive Toxicology 25: 491–496

Zhang *et al* (same lab than Wu et al., 2008) investigated the anti-androgenic activity of cyfluthrin and beta-cyfluthrin (no purities given) *in vitro* and *in vivo*; and obviously reproduced the findings of Wu et al., 2008 with cypermethrin and beta-cypermethrin. *In vivo*, anti-androgenic activity was assessed in a Hershberger assay. No effects were seen with beta-cypermethrin; however the administration of cypermethrin at 50 mg/kg bw/d is reported to result in significantly lower mean weights of the seminal vesicles, ventral and dorsolateral prostate in castrated rats treated with testosterone propionate. No effects were noted in mean weights of the LABC, Cowper's gland or glans penis. The US EPA assessment considers this study to show positive anti-androgenic effects for cypermethrin.

Classification of study: supplemental information

Report: CA 5.8.3/25
Tong J.-W. et al., 2009a
Anti-androgenic activity of Cypermethrin and Fenpropathrin in Hershberger assays
2009/1130983
Guidelines: none
GLP: no

In this study, groups of six young castrated male SD rats were administered subcutaneous injections of testosterone propionate and cypermethrin (in peanut oil; 94.1% pure) at dose levels of 0, 45, 90 or 180 mg/kg bw/d on seven consecutive days. A positive control group was administered the anti-androgen flutamide. Rats were sacrificed at 24 hours following administration of the final dose and organ weights recorded. Signs of toxicity were observed at the highest dose level; bodyweight gain was slightly (~20%) reduced in all treated groups. Absolute weights of the seminal vesicles, dorsal and ventral prostate and *levator ani* muscle were not significantly affected by treatment with cypermethrin. Serum levels of testosterone, FSH and LH were unaffected by treatment. Responses to the positive control confirmed the sensitivity of this assay. There is no evidence of anti-androgenic activity under the conditions of this assay.

Rat - 15 day adult male rat assay

Report: CA 5.8.3/26
Hu J.-x. et al., 2011a
Toxic effects of Cypermethrin on the male reproductive system: with emphasis on the androgen receptor
2011/1296731
Guidelines: none
GLP: no

Cypermethrin (commercially sourced; 97.53% pure) was assessed in a 15-day study in groups of 12-intact adult male SD rats administered gavage doses of 0, 6.25, 12.5, 25 or 50 mg/kg bw/d. Following sacrifice, weights of the testes, epididymides, seminal vesicles and prostate were recorded. One testis from each rat was used for sperm counts; the other testis was used for histopathological assessment (following fixation in Bouin's), electron microscopy and immunohistochemical analysis of the androgen receptor. Plasma levels of testosterone, FSH and LH were measured using radioimmunoassay; FSH and LH were measured using commercial kits for human hormones and are therefore of questionable relevance. Reduced weight gain was seen in rats administered cypermethrin at dose levels of ≥12.5 mg/kg bw/d; bodyweight stasis/slight weight loss over the last few days of the study is noted in rats administered 25 mg/kg bw/d but not at 50 mg/kg bw/d. Bodyweight values are not reported but are presented graphically; based on the graphical data, terminal bodyweights are estimated to be approximately 100%, 94%, 90% and 90% of controls at dose levels of 6.25, 12.5, 25 and 50 mg/kg bw/d respectively. Overall weight gains of 100%, 67%, 45% and 45% are estimated. Mean absolute prostate weight was significantly lower than controls at dose levels of 25 mg/kg bw/d (76.2% of controls) and at 50 mg/kg bw/d (78.3%); mean absolute weights of the testes, epididymides and seminal vesicles were not significantly different to controls. Relative organ weights are not reported but relative prostate weights are estimated to be approximately 85% and 88% of the control value at 25 and 50 mg/kg bw/d respectively. Daily sperm production was significantly reduced in rats administered 50 mg/kg bw/d. Histopathological assessment of the testes showed a dose-related and statistically significant increase in the proportion of seminiferous tubules showing degeneration, in all treated groups. At dose levels of 6.25 and 12.5 mg/kg bw/d, slight tubular distortion, lumen changes and reduced spermatid numbers were observed. More marked findings, including seminiferous tubular atrophy were observed at 25 and 50 mg/kg bw/d. Seminiferous tubule numbers were reduced at 6.25 and 12.5 mg/kg bw/d only. A dose-related decrease in tubular circumference was seen in all treated groups. Ultrastructurally, various changes were observed including swollen mitochondria and disruption of gap junctions. Immunohistochemistry showed significantly reduced androgen receptor levels in the Sertoli cells, Leydig cells and peritubular myoid cells at dose levels of ≥12.5 mg/kg bw/d. Significantly reduced serum testosterone levels associated with significantly increased levels of FSH and LH were seen at 50 mg/kg bw/d.
The authors conclude that cypermethrin acts as an anti-androgen in the rat, reducing androgen receptor expression. Reduced expression of the androgen receptor in Sertoli cells adversely affects spermatogenesis. Reduced expression of the androgen receptor in Leydig cells adversely affects spermatogenesis and also reduces the level of testosterone synthesis.

Remark from the applicant: The study claims that testosterone is decreased, but the expected histological findings are missing which are normally associated with reduced testosterone (retention of spermatids, apoptosis of pachytene spermatocytes and round spermatids). These findings were obviously not observed in this study and their absence was not discussed. The FSH and LH levels were detected with a human detection kit and are therefore less convincing, too. Histopathological pictures are not convincing (necrosis, atrophy and distortion is not visible).
It is notable that effects on prostate weight were not reproduced in a comparable study performed by the same laboratory at a slightly higher dose level of 60 mg/kg bw/d that did not affect bodyweights (Li *et al*; 2013). The body weights of the used animals are unusually low for animals of this strain at that age. The study is limited due to methodological defects in histopathology and RIA.

Classification of study: supplemental information

A comparable assay in the same lab was performed by Li et al (2013):

Report:	CA 5.8.3/27 Fang L.Y. et al., 2012a Effects of Cypermethrin on male reproductive system in adult rats 2013/1416880
Guidelines:	none
GLP:	no

In this study, groups of 12 male SD rats were administered cypermethrin (98% pure) by gavage at dose levels of 0, 7.5, 15, 3 or 60 mg/kg bw/d on 15 consecutive days. Rats were sacrificed within 2 hours of the final dose. No signs of toxicity were observed; bodyweights were unaffected by treatment. Absolute weights of the testes, epididymides, seminal vesicles and prostate were, in contrast to Hu et al., 2010, unaffected by treatment. Daily sperm production decreased with a dose-response relationship in all treated groups; values attained statistical significance at 30 and 60 mg/kg bw/d. Morphological assessment showed effects on seminiferous tubule diameter in all treated groups. Histopathology revealed slight distortion of the tubules at dose levels of 7.5 and 15 mg/kg bw/d; more severe effects including tubular atrophy, reduced numbers of germ cells, Sertoli cells and Leydig cells were observed at 30 and 60 mg/kg bw/d. Serum testosterone levels were reduced in all treated groups; significantly at 30 and 60 mg/kg bw/d. FSH levels were increased in all treated groups, significantly at 60 mg/kg bw/d only. A trend to higher LH levels is seen in all treated groups; however values do not attain statistical significance in any group.

Remark from the applicant: The study claims that testosterone is decreased, but the expected histological findings are missing which are normally associated with reduced testosterone (retention of spermatids, apoptosis of pachytene spermatocytes and round spermatids). These findings were obviously not observed in this study and their absence was not discussed. The FSH and LH levels were detected with a human detection kit and are therefore less convincing, too. Histopathological pictures are not convincing (necrosis, atrophy and distortion is not visible).

Rat – 30 day

Report: CA 5.8.3/28
Grewal K.K. et al., 2010a
Toxic impacts of Cypermethrin behavior and histology of certain tissues of albino rats
2010/1232204
Guidelines: none
GLP: no

Groups of male and female rats (strain unspecified) were gavaged with cypermethrin (source and purity unspecified), in arachis oil at dose levels of 5 or 20 mg/kg bw/d for 30 days. The highest dose level was sufficient to cause a low rate of mortality; signs of toxicity were observed at both dose levels. Body weights are not reported. No gross changes were apparent in the testes; however testes are reported to have appeared smaller in treated rats. A significantly lower relative testis weight (56% of controls) was seen at the highest dose level. Histopathology is reported to have revealed extensive damage to the seminiferous tubules and alterations to the histoarchitecture; however the methods used (formalin fixation) and interpretation are less than optimal. The highest dose level also produced a marked reduction in spermatogenesis. This study is considered to be of limited reliability.

Classification of study: not further considered

Rat – 45 day

Report: CA 5.8.3/29
Joshi S.C. et al., 2010a
Evaluation of reproductive and developmental toxicity of Cypermethrin in male albino rats
2011/1296732
Guidelines: none
GLP: no

Groups of six male rats (strain not reported) were gavaged with cypermethrin (technical grade; purity unspecified) at dose levels of 0, 50, 75 or 100 mg/kg bw/d for 45 consecutive days. At termination, the testes were assessed histopathologically (following fixation in Bouin's) and were additionally assessed for various biochemical parameters. Sperm motility was also assessed. Treated males were also mated with untreated females; however the exact timing of this procedure is unclear. In a separate experiment, mated female rats were gavaged with cypermethrin at dose levels of 0 or 100 mg/kg bw/d on Gestation Days 6-17. Absolute weights of the testes, epididymides, ventral prostate and seminal vesicles were significantly decreased in all treated groups; effects on the epididymides and prostate exhibit a dose-response relationship. Values are presented graphically and with apparently incorrect units. Bodyweight effects and relative organ weights are not reported; relative organ weights cannot be calculated and the effects reported on absolute organ weights cannot be interpreted. Based on findings from other studies (e.g. Hu *et al*, 2011, reduced bodyweight gain or weight loss would be expected at all dose levels used in this study. Histopathology revealed reduced size of the seminiferous tubules, the complete arrest of spermatogenesis, increased intertubular space and ruptured interstitial cells at cypermethrin dose levels of 50 and 75 mg/kg bw/d. More severe effects including reduced numbers of Leydig and Sertoli cells were seen at 100 mg/kg bw/d. Biochemical analysis of the testes revealed significantly reduced levels of glycogen and sialic acid; significantly increased levels of protein, cholesterol, acid phosphatase and alkaline phosphatase in all treated groups and with a dose-response relationship. Effects on glycogen content were particularly marked, with reductions of 76%, 88% and 92% relative to controls seen at dose levels of 50, 75 and 100 mg/kg bw/d, respectively. Levels of serum testosterone, LH and FSH were significantly reduced in all treated groups in a treatment-related manner. Testicular and epididymal sperm counts were significantly reduced by treatment in all groups; caudal sperm motility was also significantly reduced in all treated groups. Findings correlate with reduced fertility levels of 50%, 20% and 0% in the respective treated groups, compared to 100% in the controls. Reduced weight gain is reported in treated females; however values are not presented. Treatment with cypermethrin is stated to result in reduced implantation numbers, high foetal loss, reduced litter size and reduced foetal size and weight; however no values are presented. The presented absolute weight data for male reproductive organs and hormone measurements are scientifically unsufficient for interpretation without data about body weight and details on systemic toxicity. The value of the histopathological investigations in this study is limited as documented in Figures showing shrinkage artefacts by the use of Bouin's as a fixative and the apparent comparison of findings in seminiferous tubules of different stages. More generally, the study is limited by poor reporting (specifically the lack of any information on systemic toxicity or bodyweight data) and the use of relatively high dose levels.

Classification of study: not further considered

Rats - 12-week

Report: CA 5.8.3/30
Elbetieha A. et al., 2001a
Evaluation of the toxic potentials of Cypermethrin pesticide on some reproductive and fertility parameters in the male rats
2001/1031943
Guidelines: none
GLP: no

Groups of male SD rats (approximately three months old) were administered cypermethrin (as the commercial product 'Cypermethrin 10') in the drinking water at dose levels stated to be equivalent to 0, 13.15, 18.93 or 39.66 mg/day (calculated to be equivalent to approximately 45, 63 and 132 mg/kg bw/d, based on an initial bodyweight of 300 g). Dose levels are reported to be equivalent to 2.5%, 5% and 10% of the LD_{50} (which is reported to be 4123 mg/kg bw in water). Males were treated for 12 weeks and then mated (1:2) with untreated females. Rats were cohabited for 10 days, after which point males were sacrificed; females were sacrificed after a further 10 days. Weight loss was reported for males in the intermediate dose group (~10% of the initial bodyweight); more marked weight loss (~16%) was seen at the highest dose level. Weight gain in the low dose group (~10 g) was comparable to controls. Effects on fertility (reduced numbers of pregnant females, implantation sites and viable foetuses; increased resorptions) were seen in all treated groups. Absolute weights of the testes, seminal vesicles and preputial gland were significantly increased in treated groups; sperm counts and daily sperm production were significantly reduced. Microscopically, the testes of treated rats were found to have congested blood vessels, haemorrhage around the semiferous tubules and increased connective tissue between tubules. Testicular morphology was also altered in exposed rats. At the highest dose level, serum levels of testosterone, FSH and LH were all significantly lower than controls. The reliability of this study is limited by the use of a commercial product containing relatively high levels of organic solvent and other co-formulants. Furthermore this report shows a high degree of additional methodological deficits, missing of relevant data in regard to general toxicity, mistakes in data presentation and questionable interpretation. **This study has been already discussed in the Zeta-Cypermetrhin DAR (2008) and was classified as questionable.**

Rat – GD 7-21

Taxvig *et al* (2013) see CA 5.8.3/24 2013/1416882
In vitro - in vivo correlations for endocrine activity of a mixture of currently used pesticides
Toxicology & Applied Pharmacology 272: 757-766

In the *in vivo* phase of this study, groups of 12 female mated Wistar rats were gavaged with mixtures of 3 (Mix3) or "3 plus additional 2" (Mix5) pesticides (including cypermethrin as one of Mix3 and Mix5) on Gestation Days 7-21. Mixtures included compounds administered in equal proportions at single compound dose levels of 1, 3 or 10 mg/kg bw/d. No effects were seen on maternal bodyweight or adjusted bodyweight for Mix3. Plasma hormone levels in dams treated with Mix3 were unaffected for estradiol, progesterone, T3 and T4 at GD21. Litter parameters were unaffected by treatment and anogenital distance was comparable in all groups. Testosterone levels in placentas were unaffected in the Mix3 up to the highest dose as well as testiculare hormone levels in pups on GD21. No histopathological changes of testes were seen. Cypermethrin and its metabolite M310I011 were detected in the amniotic fluid from rats of all treated groups. The authors conclude that this study provides evidence that all single pesticides are able to affect steroidogenesis in vitro, but only the Mix5 exerted endocrine activity in vivo in dams and female fetuses, but that this is due to terbuthylazine. In conclusion, doses up to 10 mg/kg bw cypermethrin were not able to affect endocrine system in Wistar rats in vivo.

Classification of study: supplemental information

Mouse – PND 0-21

Report: CA 5.8.3/31
Wang H. et al., 2009a
Maternal Cypermethrin exposure during lactation impairs testicular development and spermatogenesis in male mouse offspring
2010/1232193
Guidelines: none
GLP: no

Groups of maternal female ICR mice were administered cypermethrin (Sigma) by gavage (in corn oil) at dose levels of 0 or 25 mg/kg bw/d from PND 0-21. Twelve male pups from six litters per group were sacrificed at PND 21 or PND 70. There were no signs of maternal toxicity; bodyweights were unaffected by treatment. Pup weights are not shown. Testes weights in pups (sacrificed at PND 21) from treated female mice were significantly lower than controls. Histopathology of the testes (limited methodological details presented) is reported to show a marked reduction in the layers of spermatogenic cells and an increased seminiferous tubule internal diameter in the treated group. Immunostaining did not show any difference in the numbers of Leydig cells between the treated and control groups; no significant differences in the number of apoptotic cells (investigated using TUNEL) were seen. Serum testosterone levels were markedly lower in the offspring of treated mice and testicular testosterone levels were also significantly lower; however the relevance of measuring serum testosterone levels in very young animals is questionabledue to the fluctuations of testosterone levels with regard to the prenatal surge of testosterone at around day 5, then very low levels of this hormone until puberty (day 35) starting to increase again at around day 25 (descend of testis). Levels of testicular cytochrome P450scc mRNA and protein were significantly lower in the offspring of treated mice. Testicular StAR, 17beta-HSD and $P450_{17\alpha}$ mRNA levels were slightly lower in the offspring of treated mice; however no significant effect was seen on levels of the corresponding proteins. In adult males (sacrificed at PND 70), maternal treatment with cypermethrin was shown to have a slight but significant negative effect on testes weight and epididymal sperm count (although findings are not normalised for epididymal weight and therefore the result is questionable). Histopathology of the testes showed disturbed spermatogenesis and an increase in the internal diameter of the seminiferous tubules. No significant effects were seen on serum testosterone levels or on testicular mRNA or protein levels of cytochrome P450scc mRNA, StAR, 17β-HSD and $P450_{17\alpha}$. Following mating with untreated females, no differences in fertility or litter parameters were seen between the males from treated or untreated mothers. The authors conclude that exposure to cypermethrin during lactation causes temporary endocrine disruption but permanent effects on testicular development and spermatogenesis in male offspring. The study is considered to be of limited value due to significant methodological flaws.

Classification of study: not further considered

Mouse – PND 21-42 study

Report: CA 5.8.3/32
Jin Y. et al., 2011a
Cypermethrin exposure during puberty induces oxidative stress and endocrine disruption in male mice
2011/1296733
Guidelines: none
GLP: no

Groups of young male ICR mice were orally administered cypermethrin at dose levels of 0, 5, 10 and 20 mg/kg bw/d (assumed to be by gavage) from PND 21-42 and sacrificed on the last day of treatment. At termination, the livers were removed, homogenised and assessed for markers of oxidative status. The expression of genes encoding antioxidant proteins was also assessed. General toxicity is not reported. Slight, but significant increases in superoxide dismutase, glutathione peroxidase and catalase activities were seen at the highest dose level only; malondialdehyde levels were unaffected. Total antioxidant capacity was reduced in all treated groups; significantly at 10 and 20 mg/kg bw/d. Hepatic superoxide dismutase and glutathione peroxidase mRNA levels were significantly increased at dose levels of 10 and 20 mg/kg bw/d; levels of catalase mRNA were unaffected by treatment. Hepatic HMG-CoA reductase levels were unaffected by treatment; however HMG-CoA synthase levels were markedly reduced. Testicular StAR mRNA levels were significantly reduced at 20 mg/kg bw/d. Testicular levels of P450scc and P450 17β-HSD were similar in all groups; however levels of P450 17α were significantly reduced at dose levels of 10 and 20 mg/kg bw/d. Serum testosterone level was slightly (but significantly) lower at 20 mg/kg bw/d. The study therefore indicates that endocrine effects are related to oxidative stress following the administration of cypermethrin to young male mice; however it is notable that effects were seen only in the presence of hepatic effects.

Report: CA 5.8.3/33
Wang H. et al., 2009b
Cypermethrin exposure during puberty disrupts testosterone synthesis via downregulating StAR in mouse testes
2010/1232194
Guidelines: none
GLP: no

Groups of male CD-1 mice (group size not reported) were gavaged with cypermethrin (sourced from Sigma) in corn oil at a dose level of 25 mg/kg bw/d from PND 35-70. No bodyweight effects were seen; signs of toxicity are not reported. Weights of the testes and epididymides were unaffected by treatment; however epididymal sperm count (not normalised to epididymal weight) was significantly reduced in treated mice. Treated mice showed changes to the architecture of the seminal vesicles and an increase in the number of apoptotic (TUNEL-positive) cells. Serum and testicular levels of testosterone were significantly lower in treated mice. Levels of testicular StAR protein and cytochrome $P450_{17\alpha}$ were significantly lower in cypermethrin-treated mice; levels of P450scc and 17β-HSD were unaffected by treatment. Immunostaining did not show any difference in the numbers of Leydig cells between control and treated mice.

Mouse – 5 day i.p.

Report: CA 5.8.3/34
Kumar S. et al., 2003a
Demonstration of sperm head shape abnormality and clastogenic potential of Cypermethrin
2004/1040396
Guidelines: none
GLP: no

Groups of male Swiss mice were administered cypermethrin (no further details provided) by intraperitoneal injection (in 0.15% DMSO) at dose levels of 0, 30, 60 and 90 mg/kg bw/d for five days. Animals were sacrificed on the 35th day, the testes weighed and caudal epididymal sperm visually assessed for abnormalities following staining with eosin-Y. Reduced weight gain was seen in mice administered 60 and 90 mg/kg bw/d cypermethrin. No significant effects of treatment were seen on testes weight. The proportion of abnormal sperm (various abnormalities of head shape) was significantly increased in mice at toxic dose levels of 60 and 90 mg/kg bw/d from 1.13% to approximately 2.5-3%. The relevance of this study is questionable due to the use of intraperitoneal dosing at comparatively high dose levels.

Classification of study: not further considered

Mouse – 14 days

Report: CA 5.8.3/35
Shaikh T.M.,Elfayoumi R.I., 2013a
Protictive effects of vitamine E against testicular enzymes toxicity induced by Cypermethrin in mice
2013/1417280
Guidelines: none
GLP: no

Groups of ten male MF1 mice were administered cypermethrin (as an unspecified 10% commercial product) by gavage in corn oil at dose levels of 0 or 2.8 mg/kg bw/d for 14 days. Additional groups were administered Vitamin E (100 mg/kg bw/d) or cypermethrin and Vitamin E. Testis weights were recorded and the levels of testicular enzymes were assessed following homogenisation. General toxicity is not reported. Mean absolute testis weight was significantly reduced in the group administered cypermethrin (to 77% of the control value); significant protection was seen in the group administered cypermethrin and Vitamin E (90% of the control value). Testicular homogenates from cypermethrin-treated mice showed significantly lower activities of AST, ALT, Acid Phosphatase (AcP), ALP and a markedly higher level of LDH. Co-administration of Vitamin E was shown to afford considerable protection against the effects of cypermethrin. The toxicological significance of these biochemical effects is unclear and do not appear to be directly relevant to an endocrine MoA. The reliability of the study is further limited through the use of a commercial product (likely to contain high levels of organic solvent and other co-formulants) and in the absence of any reporting of general toxicity. More generally, the study is poorly reported and the graphical data presented indicate an unusually low level of variation.

Cypermethrin effects on the adult mice seminal glands
2009/1130984
Guidelines: none
GLP: no

Groups of 15 male CF1 mice were administered cypermethrin (92.5% purity; in vegetable oil) by a single intraperitoneal injection at a dose levels of 0 or 485 mg/kg bw. Three mice per group were sacrificed at time points of up to 34 days following treatment and the 'seminal glands' subjected to morphometric and histopathological assessment. In treated mice, significantly increased epithelial cell height was seen at 24 hours, with recovery at later time points. Cellular proliferation (measured by immunostaining for the marker protein Ki-67) was markedly increased at 24 hours only. Mast cell recruitment was significantly increased at 24 hours and continued to increase at subsequent time points. The endpoints morphometric analysis of epithelium height in the stretched and folded seminal glands and mast cell quantification are no validated endpoints and their interpretation is impossible without knowledge of the usual variation of these parameters. The toxicological relevance of the findings of this study is unclear, particularly given the use of a high intraperitoneal dose level and the small group size.

Mouse – 6 / 12 week treatment with recovery

Report: CA 5.8.3/37
Al-Hamdani N.M.H.,Yajurvedi H.N., 2010a
Cypermethrin reversibly alters sperm count without altering fertility in mice
2010/1232192
Guidelines: none
GLP: no

Groups of 5 male Swiss mice were gavaged with cypermethrin (in water; as the commercial product Superkiller 10% EC) at dose levels of 1.38, 2.76 or 5.52 mg/kg bw/d on alternate days for 6 or 12 weeks, with or without a 6-week recovery period. Additional groups of treated males were mated with untreated females, following treatment for 6 weeks. General toxicity is not reported. Sperm counts were reduced in all treated groups, but effects were shown to be largely reversible after 6 weeks treatment withdrawal. The numbers of abnormal sperm were similarly significantly higher in all treated groups and were largely reversible after a further 6 weeks without treatment. No significant effects were seen on litter size, but litter weights were significantly lower in all treated groups. The reliability of this study is limited by the use of a commercial product containing relatively high levels of organic solvent and other co-formulants.

Al-Hamdani N.M.H.,Narasinhachary Y.H., 2011a
Endocrine disruptive action of Cypermethrin in male mice
2011/1296735
Guidelines: none
GLP: no

Groups of 5 male Swiss mice were gavaged with cypermethrin (in water; as the commercial product Superkiller 10% EC) at dose levels of 1.38, 2.76 or 5.52 mg/kg bw/d on alternate days for 6 or 12 weeks with or without a 6-week recovery period. Bodyweight effects were seen in all treated groups, with weight loss observed at Weeks 8 and 12. Relative weights of the testes, epididymides, vas deferens, seminal vesicles and prostate were lower in all treated groups and generally showed a dose-response relationship. Some evidence for recovery was seen; however some organ weights were lower following the recovery period. Histopathology of the testes of treated mice revealed reduced spermatogenesis, degenerate spermatids, exfoliated spermatocytes, congested blood vessels and vacuolation of the seminiferous tubules. Recovery was seen at the low dose level but not at the highest dose level. Testicular architecture was also affected by treatment. Marked reductions in serum testosterone levels were seen in all treated groups; some evidence of recovery was seen at low and mid-dose levels following the 6-week treatment and at the low dose level following treatment for 12 weeks.

Rabbit – 71 day i.p. administration

Report: CA 5.8.3/39
Ahmad L. et al., 2012a
Toxico-pathological effects of Cypermethrin upon male reproductive system in rabbits
2012/1367122
Guidelines: none
GLP: no

Adult male NZW rabbits 'procured from the local market' were administered cypermethrin technical (92% purity) in mustard oil by intraperitoneal injection at dose levels of 0, 50, 100 or 150 mg/kg bw at weekly intervals for ten weeks. Rabbits (2/group) were terminated at weekly intervals. The testes and epididymides were weighed and subject to histopathology. Sperm head counts were made from homogenised testes or epididymides. Serum testosterone concentrations were also measured. Signs of toxicity were observed in cypermethrin-treated groups; weight gain was reduced in all treated groups in a dose-related manner. Weights of the testes and epididymides were variable, but were higher in treated groups compared to controls. Grossly, the testes of treated animals appeared to be swollen. Microscopically, treated groups showed reduced spermatogenesis and the proliferation of connective tissue. Spermatogenic gain cells and apoptotic bodies were also seen at the higher dose levels. Testicular findings showed a time- and dose-response relationship. Sperm head counts were reduced in all treated groups; values often attained statistical significance. Significantly reduced serum testosterone concentrations were seen in all treated groups. The reliability of this study is limited by the use of intraperitoneal dosing, high dose levels, small group size and the potential confounding influence of systemic toxicity.

Rabbit – 12 week

Report: CA 5.8.3/40
Yousef M.I. et al., 2002a
Protective role of Isoflavones against the toxic effect of Cypermethrin on semen quality and testosterone levels of rabbits
2003/1034259
Guidelines: none
GLP: no

Groups of six male NZW rabbits were administered cypermethrin (as a commercial 25% EC product) at dose levels of 0 or 24 mg/kg bw/d on alternate days for 12 weeks. Additional groups were administered isoflavones (genistein / daidzein mixture) at 2 mg/kg bw/d, or a combination of cypermethrin and isoflavones. Rabbits administered cypermethrin were of lower bodyweight at the end of the study period; however initial bodyweights are not reported. Food consumption was also lower in this group. Relative testes and epididymal weights were significantly lower in the cypermethrin-treated group; serum testosterone concentration was also significantly lower. Co-administration of isoflavones demonstrated a protective effect. Treatment with cypermethrin resulted in reduced ejaculate volume, increased reaction time; reduced sperm output, sperm concentration and motility and an increase in the proportions of abnormal and dead sperm. Co-administration of isoflavones again demonstrated a protective effect. The authors attribute the protective effects of isoflavone administration to its role as an antioxidant; however this conclusion is not considered to be particularly robust in the absence of consistent data for the role of isoflavones as antioxidants and also considering their documented hormonal effects. There is no measurement of endpoints directly related to oxidative stress in this study and reporting of other effects is limited by the absence of any indication of variability (results presented as graphs without error bars). Treatment with isoflavones alone in this study is also noted to have some beneficial effects on sperm parameters, which is somewhat surprising given the well documented oestrogenic effects of genistein. The study is considered to be of limited reliability.

Classification of study: supplemental information

Investigations with beta-cypermethrin

Rat - 15 day adult male rat assay

Report: CA 5.8.3/41
Liu L. et al., 2010a
Effects of Beta-Cypermethrin on male rat reproductive system
2010/1232198
Guidelines: none
GLP: no

Groups of 10 intact male SD rats were gavaged with beta-cypermethrin (>95% pure) at dose levels of 0, 15 or 30 mg/kg bw/d for 15 consecutive days. Signs of toxicity were not reported; weight gain was unaffected by treatment. Mean relative weights of the testes, epididymides and seminal vesicles were unaffected by treatment. Sperm head count (reflecting spermatogenic cell death) and thereof calculated daily sperm production were significantly reduced in both treated groups. Immunohistochemical analysis of androgen receptor levels revealed significantly reduced levels in both treated groups, with a dose-response relationship evident.
Remark from the applicant: Histopathology of the testes in this study was performed following formalin fixation, which may result in the production of artefacts including tubular shrinkage and chromatin condensation; immunohistochemial staining of Androgen receptor was not done in stage-aware fashion thereby the different expression patterns of stage V-VI and stage IX versus stage VII-VIII sertoli cells/seminiferous tubule are not considered. Assessments are therefore considered to be of limited reliability.

Classification of study: supplemental information

Mice – 35 days

Report: CA 5.8.3/42
Wang X.-Z. et al., 2009a
Beta-Cypermethrin impairs reproductive function in male mice by inducing oxidative stress
2009/1130986
Guidelines: none
GLP: no

Groups of ten male Kunbai mice were administered beta-cypermethrin (>99% pure) by gavage (in corn oil) at dose levels of 1, 10 or 20 mg/kg bw/d for 35 days. Reduced weight gain was seen in all treated groups; absolute weights of the testes, epididymides, seminal vesicles and prostate were reduced in treated groups. The co-administration of Vitamin E (20 mg/kg bw/d) with beta-cypermethrin (20 mg/kg bw/d) was shown to afford protection against bodyweight and organ weight effects. Reduced sperm counts and sperm viability were seen in treated groups; sperm motility was decreased and acrosome deformity was significantly increased at the highest dose level. A protective effect of Vitamin E was also seen on sperm parameters. At the low dose level, a decrease in the number of Leydig cells was observed. At the highest dose level, a marked effect was seen and spermatids were nearly completely absent from the lumen of the seminiferous tubules. Epididymal sperm were also nearly completely absent in this group. The effects on sperm count were prevented by co-administration of Vitamin E. Administration of beta-cypermethrin was also shown to cause ultrastructural effects in Leydig cells; a protective effect of Vitamin E was seen. The higher dose levels of beta-cypermethrin were shown to increase testicular malondialdehyde levels, levels of NO were also increased; these effects were reversed by Vitamin E. Total and inducible NO-synthase levels were increased in all treated groups; a protective effect of Vitamin E was apparent. Administration of beta-cypermethrin at the two higher dose levels was also shown to reduce the activities of catalase, glutathione peroxidase and SOD. The authors therefore conclude that the observed effects of beta-cypermethrin on the testes are due to oxidative stress.

Classification of study: supplemental information

Report: CA 5.8.3/43
Yulan Z. et al., 2009a
Beta-Cypermethrin induces Sertoli cells dedifferentiation by oxidative stress
2010/1232200
Guidelines: none
GLP: no

Male mice were gavaged with beta-cypermethrin (>99% pure) at dose levels of 0 or 20 mg/kg bw/d with or without Vitamin E (15 mg/kg bw/d) for 35 days. After termination, the testes were subjected to immunohistochemical analysis or measurement of total antioxidant capacity. General toxicity is not documented. In testes from the control group, PCNA staining was seen in nuclei from spermatogonia at the base of the seminiferous tubules. Staining was not detected in Leydig, Sertoli or spermatogenic cells. In mice treated with beta-cypermethrin, PCNA staining of spermatogonia was significantly reduced, but staining was seen in the Sertoli cells. In mice administered beta-cypermethrin and Vitamin E, PCNA expression in the Sertoli cells was reduced. In testes from the control group, Connexin 43 (Gap Junction alpha-1 protein; a marker of differentiation) staining was seen mainly in the in Leydig cells, but also in Sertoli cells and spermatocytes. No staining was observed in spermatids or sperm. In mice treated with beta-cypermethrin, Leydig cell staining was significantly reduced, as was staining in Sertoli cells and spermatocytes. This effect was not seen in the testes of mice administered beta-cypermethrin and Vitamin E. Total Antioxidant Capacity was markedly reduced in the testes of mice administered beta-cypermethrin; this effect was almost completely abolished by co-treatment with Vitamin E. The authors conclude that beta-cypermethrin administration to mice causes Sertoli cell de-differentiation and proliferation as a result of induced oxidative stress. The accuracy of this report is less than optimal: Methods are described (immunohistochemical detection of substance P which was definitely not performed. Based on the fact that similar endpoints (total oxidative capacity and the effect of vitamin E) are discussed in detail elsewhere (see Wang et al., 2009), this report is not further considered.

Classification of study: not further considered

Investigations with alpha-cypermethrin

Rat – 30 day

Manna *et al* (2004) see CA 5.3.1/1 2004/1040514
Repeated dose toxicity of alfa-cypermethrin in rats
J. Vet. Sci 5(3): 241-245

Adult Wistar rats (5/sex) were gavaged with alpha-cypermethrin (in DMSO; >99% pure) at dose levels of 0 or 14.5 mg/kg bw/d (equivalent to 10% of the LD50) for 30 days. Signs of toxicity are not reported; however clinical chemistry analyses reported significant effects of treatment including elevated ALP, AST, ALT and LDH activity; haematology revealed effects including a marked reduction in erythrocyte count. Necropsy revealed severe gastrointestinal haemorrhage. Significantly lower liver CAT and SOD activity were reported; liver malondialdehyde level was significantly reduced. The glutathione level was slightly lower; glycogen and cytochrome P450 levels were significantly lower. The pattern of induced enzymes nevertheless strongly suggests oxidative metabolism. Interestingly the GSH level is still unaffected in this study, which indicates a partially unimpaired anti-oxidative system in the liver (see copied tables from the publication).

Table 2. Effects of α-CP on certain biochemical parameters in serum and blood of rats after daily oral administration at 14.5 mg/kg for 30 days (Values are mean ± SE, n = 10)

Parameters	Control	α-CP treated
ALP activity (IU/L)	78.03 ± 2.58	161.53 ± 6.60*
AST activity (IU/L)	59.45 ± 3.52	72.00 ± 4.97*
ALT activity (IU/L)	12.00 ± 1.43	26.50 ± 1.67*
LDH activity (IU/L)	49.41 ± 2.58	64.80 ± 2.01*
TP (gm/dl)	8.12 ± .022	6.41 ± 0.17*
ALB (gm/dl)	4.53 ± 0.29	4.50 ± 0.26
GLB (gm/dl)	3.81 ± 0.21	2.16 ± 0.49*
Blood Glucose mmol/L	3.70 ± 0.48	6.22 ± 0.85*

*$p < 0.05$ in comparison with control
ALP: Alkaline Phosphatase, AST: Aspartate transaminase, ALT: Alanine transaminase; LDH: Lactate dehydrogenase, TP: Total protein; ALB: Albumin; GLB: Globulin.

Table 3. Effects of α-CP on certain biochemical parameters in liver of rats after daily oral administration at 14.5 mg/kg for 30 days (Values are mean ± SE, n = 10)

Parameters	Control	α-CP treated
CAT activity (U/mg protein)	0.39 ± 0.04	0.07 ± 0.01*
SOD (U/mg protein)	0.48 ± 0.02	0.13 ± 0.01*
MDA (nmol/mg protein)	0.24 ± 0.02	2.85 ± 0.18*
GSH (μmol/mg protein)	1.41 ± 0.16	1.30 ± 0.05
Glycogen (mg%)	7.94 ± 0.24	5.15 ± 0.34*
P450 (nmol/mg microsomal protein)	2.91 ± 0.02	2.74 ± 0.04*
b5 (nmol/ mg microsomal protein)	1.16 ± 0.07	1.28 ± 0.05

*$p < 0.05$ in comparison with control
CAT: Catalase, SOD: Superoxide dismutase, MDA: Malondialdehyde, GSH: Reduced glutathione.

Histopathology of the testes (Bouin's used as fixative) is reported to reveal interstitial oedema and vacuolation of the seminiferous tubules, otherwise care should be taken when tissue *pieces* are used for histopathology based on squeezing artefacts of tissues. The reliability of this study is therefore limited by confounding toxicity and sub-optimal histopathological methods.

Classification of study: supplemental information

Mouse – 28 day

Prakash *et al* (2010) see CA 5.3.1/2 2010/1232197
Evaluation of Testicular Toxicity Following Short-term Exposure to Cypermethrin in Albino Mice
Toxicology International 17(1):18-21

Groups of 6 male Swiss mice were gavaged with alpha-cypermethrin (>99% purity; in arachis oil) at dose levels of 0 (controls) or 250 mg/kg bw/d for 14 or 28 days. No bodyweight effects are reported; sign of toxicity are not specifically mentioned but would be expected at this dose level. Weights of the testes, seminal vesicles, prostate gland and epididymides are reported to be increased; however values are not actually reported. AST activity in testicular homogenates was significantly reduced at Day 14 and slightly (but significantly) increased at Day 28. ALT activity was significantly increased, ALP activity was significantly reduced and cholesterol levels were significantly increased. The toxicological significance of these biochemical investigations is unclear. Plasma testosterone levels are stated to be significantly decreased at both time points; however a high level of variation is apparent and the level of significance is not reported. However, the weight increase of testes and accessory glands combined with testosterone decrease are not convincing. Histopathology revealed various testicular changes; however methodological data are deficient and the methods used are known to produce artefacts. TEM also revealed ultrastructural effects in the treated groups but no control data are shown for comparison. The described findings like rupture of cell membrans, increased lipochrome pigment and shrinkage in the nucleus, or decreased cytoplasmic organelles are not seen in the pictures. There is no indication that the histopathological evaluation was performed in a stage aware fashion and therefore it is questionable if tubuli of the same stage were looked at. Overall the study is considered to have significant methodological and reporting deficiencies and additionally used a very high dose level of alpha-cypermethrin likely to have resulted in significant general toxicity.

Classification of study: not further considered

Rabbit – 28 day dermal application

Aksoy et al (2009) see CA 5.3.3/1 2009/1130982
Investigation of potential testicular toxicity of subchronic dermal application of alphacypermethrin in rabbits
J. vet. Pharmacol. Therap. 32 (Suppl. 1), 129–265

In this poster presentation, groups of seven male NZW rabbits were dermally administered alpha-cypermethrin (source/purity not reported; in DMSO) daily at dose levels of 0, 40, 200 or 1000 mg/kg bw/d for 28 days. No deaths occurred; however partial paralysis was apparent in rabbits at the highest dose level. Bodyweights were reported to have been unaffected by treatment. The proportion of abnormal spermatozoa was significantly higher in treated groups and in a dose-dependent manner. Histopathological investigation of the testes revealed severe degeneration including vacuolation between spermatogonial cells, collapsed/shrunken tubules, decreased spermatogonial cell count and intratubular giant cell formation. The severity of the testicular findings was dose-related. The reliability of this reference is very limited due to the lack of methodological data.

Classification of study: not further considered

Investigations with metabolites

Rat – 90 day

Beck L.S. (1991a) and Halliwell W.H. (1991a) see CA 5.8.1/34 1980/1001707 and CA 5.8.1/35 1980/1001708
Histopathologic Evaluation of Tissues and Organs from albino rats in a 90 day subchronic oral dosing study with meta-Phenoxybenzylaldehyde (3-PBAld) provided by Ethyl Corporation

The study is described in detail under section CA 5.8.1/34 and 5.8.1/35 and suffers some weaknesses with regard to unequal dose volume, non GLP etc. Nevertheless it gives some insight into the relevance of the *in vitro* anti-androgenic activity of 3-phenoxybenzaldehyd. Sprague Dawley rats were administered 3-PBAld in corn oil via gavage over a period of 90 days at dose levels of 50, 150, or 300 mg/kg bw/d. Organ weights were measured for liver, kidneys, adrenals, gonads, heart, spleen and brain. In addition to those mentioned organs histopathology was performed on all animals of the control and high dose group on parathyroid gland, pituitary gland, prostate, and thyroid gland as well as uterus. Abs. and rel. organ weights for adrenals, testes and uterus were unaffected and histopathology revealed no effect on endocrine organs (adrenal gland, parathyroid, pituitary gland and thyroid) or the reproductive system (epididymis, prostate, seminal vesicles, testes, cervix, uterus, ovaries, uterine horns, and vagina) that could be attributed to the test substance. The LOAEL was determined at 150 mg/kg bw as based on effects on liver and kidney weights. The results of this 90 day study show that the in vitro found anti-androgenic effect of 3-PBAld is not displayed in vivo.

Classification of study: supplemental information

Overview of studies in male animals *in vivo*

A large number of studies investigating effects in male animals are available for cypermethrin, alpha- or beta-cypermethrin. The results of some of these studies are limited by the use of commercial cypermethrin products which are likely to contain high levels of organic solvent components. A number of studies investigating testicular histopathology are also limited by the use of non-current terminology, the absence of staging assessment and tissue processing methods including fixation in Bouin's fluid or formalin, which may result in the production of artefacts. A number of studies are also limited through the use of non-physiological (intraperitoneal) dosing routes, the use of excessively high dose levels and/or the lack of reporting of general systemic toxic effects.
Wu et al., (2008) and Zhang *et al* (2008) report a positive response in a Hershberger assay with cypermethrin in SD rats at relatively high oral dose levels of 63 mg/kg bw (no positive response at 7 and only prostate weight reduced at 21 mg/kg bw) and 50 mg/kg bw/d (the only dose level investigated); a negative result is reported for beta-cypermethrin at 6, 18, 54 mg/kg bw by Wu et al., 2008 and at 50 mg/kg bw by Zhang et al., 2008. Findings are consistent with the results of studies *in vitro* which report weak anti-androgenic effects for cypermethrin but not for beta-cypermethrin, possibly due to metabolites. A negative result for reproductive organ weight changes is reported for cypermethrin by Tong *et al* (2009) at higher dose levels (up to 180 mg/kg bw/d); however this study used subcutaneous dosing. The US EPA assessment considers the Zhang *et al* (2008) study to be sufficiently robust to meet the data requirement for a Hershberger assay. Organ weight effects are also noted by a number of other authors. Weights of androgen-sensitive organs and tissues (prostate, testis, seminal vesicle, epididymides) are generally reported to have been reduced by treatment; For example Hu et al., 2011, reported significant organ weight effects on seminal vesicles and prostate at 50 mg/kg bw, however 2 years later the same lab published under Li *et al* (2013) a compareable study with higher dose levels but no effects on organ weights in intact rats administered cypermethrin at gavage dose levels up to 60 mg/kg bw/d (i.e. a dose level higher than that assessed in the Hershberger assay of Zhang *et al* (2008) and similar to that used in the Hershberger of Wu et al., 2008). Elbetieha *et al* (2001) report significantly increased organ (testes and seminal vesicle) weights in rats administered a commercial product containing 10% cypermethrin; however it is possible that other components of the formulation contribute to this effect. Based on *in vitro* data showing a difference in anti-androgenic activity between cypermethrin (active) and beta-cypermethrin (inactive) and the likely role of metabolism in the anti-androgenic potential of cypermethrin, it is considered unlikely that alpha-cypermethrin would show anti-androgenic effects in the Hershberger assay. This is supported by the positive response to cypermethrin but not to the same dose level of beta-cypermethrin reported by Wu et al., (2008) and Zhang *et al* (2008) and also by the 15 day adult rat male assay by Liu *et al* (2010) with beta-cypermethrin. Data indicate that the weak anti-androgenic activity of cypermethrin (and other pyrethroids) is associated with metabolites. The greater level of metabolism of *trans*-isomers compared to *cis*-isomers might explains the lower activity of beta-cypermethrin (which contains a lower proportion of *trans*-isomers) and would also predict an absence of activity for alpha-cypermethrin (which consists entirely of *cis2*-isomers). An anti-androgenic effect however was not reproducible under in vivo circumstances with the most potent in vitro metabolite 3-phenoxybenzaldehyde.

Testicular histopathology is noted in a number of studies; however the reliability of a number of studies is questioned due to the use of tissue fixation and processing methods known to produce artefacts such as tubular shrinkage and chromatin condensation; in the respect it is notable that changes to tubular histoarchitecture are reported by a number of authors. The study of Grewal *et al* (2010) is not considered to be reliable in the absence of any documentation of systemic toxicity and due to poor fixation techniques. The study of Wang *et al* (2010b) uses Bouin's fixation which can induced shrinkage artefacts and the histopathological interpretation is less than optimal. It is notable in this study that sperm effects were associated with oxidative stress and bodyweight effects, which would indicate specific organ toxicity rather than effects mediated through an endocrine MoA. This conclusion is further supported by the protective effect of Vitamin E.

Highly interesting are the 15 day intact male rat studies of Hu *et al* (2011) and Li *et al* (2013) which appear to be generally reliable. Although the studies are not entirely consistent with regard to reproductive organ weight effects (reported at the dose level of 25 and 50 mg/kg bw/d by Hu *et al*, 2011 but not at the highest dose level of 60 mg/kg bw/d by Li *et al*), both studies report effects on the testes (histopathology and reduced sperm production) associated with a reduction in serum testosterone levels. Reduced sperm production after substance administration in corn oil was seen with cypermethrin from doses of 30 mg/kg bw/day onwards, with beta-cypermethrin from 15 mg/kg bw onwards. Under the hypothetical assumption that sperm toxicity is attributed to the cis2-Isomers, this would imply an effect with alpha-cypermethrin at 6.6 mg/kg bw (22% of the cypermethrin) or 6 mg/kg bw (40% of beta-cypermethrin).
The 71day i.p. rabbit study of Ahmad *et al* (2012) is of very limited value to the use of a non-physiological route of administration (intraperitoneal injection), the high dose levels used and the lack of reporting of systemic toxicity, and the very small group size. The rabbit study of Yousef *et al* (2011) is of limited value due to the use of a commercial product. While the study reports protection against the testicular effects by co-administration of an isoflavone mixture, there is no direct evidence for any effects on oxidative status. Isoflavones such as genistein are additionally known to have hormonal effects. The rabbit study of Aksoy *et al* (2009) using dermal administration of alpha-cypermethrin is a poster abstract and, as such, contains only very limited methodological information. The mouse pubertal study of Jin *et al* (2011) reports the down-regulation of genes involved in cholesterol transport and testosterone synthesis, resulting in reduced levels of circulating testosterone. Findings are associated with oxidative stress and, additionally, the liver appears to be more sensitive than the testes. Effects in the testes may therefore be secondary to other effects and do not represent an endocrine MoA. The study of Wang *et al* (2010a) is not considered to be reliable due to serious deficiencies in methodology and reporting. While this study suggests that a reduction in circulating testosterone may be due to reduced expression of testicular StAR and $P450_{17\alpha}$ mRNA, results are not entirely consistent with other similar studies. Jin *et al* (2011) also report the down-regulation of testicular StAR and $P450_{17\alpha}$ mRNA, but Wang *et al* (2010b) report the down-regulation of testicular StAR and $P450_{scc}$ mRNA. The study of Rodriguez *et al* (2009) is severely limited due to the use of a very high intraperitoneal dose. Liu *et al* (2010) report a reduction in androgen receptor expression as responsible for reduced spermatogenesis in mice exposed to beta-cypermethrin. The study is limited in terms of methodology due to the use of formalin fixation (which is known to induce artefacts); immunochemical staining for the androgen receptor was not standardised according to stage. Joshi *et al* (2011) used Bouin's as a fixative and testicular histopathology was not standardised for stages. The study is additionally not considered to be reliable in the absence of

any information on systemic toxicity or bodyweight; based on data from other studies, general toxicity would be predicted at the dose levels used. Elbetieha *et al* (2010) used a commercialformulation of cypermethrin; the results of this study are therefore of limited relevance. The studies of Al-Hamdani & Narasinhachary (2010, 2011) are not considered to be reliable due to the use of a commercial formulation of cypermethrin. The study of Prakash *et al* (2010) has significant methodological deficiencies including the use of Bouin's as a fixative and the absence of information on stage standardisation for the histopathological assessment. The dose level used in this study (250 mg/kg bw/d) is very high and would be predicted to result in significant general toxicity, although findings are not discussed. Biochemical investigation of homogenised testes shows significant differences in the activities in some enzymes (ALT, AST, ALP); however the toxicological significance of this finding is unclear. The study is not considered to be sufficiently reliable. Manna *et al* (2004) report histopathology associated with effects of alpha-cypermethrin on oxidative status in the testes; however this would appear to a non-specific effect as findings were associated with general toxicity and effects on hepatic oxidative status. The study of Kumar *et al* (2004) reports the induction of sperm abnormalities by cypermethrin, but is of limited relevance due to the use of a relatively high intraperitoneal dose. Zhou *et al* (2010) report the induction of oxidative stress in mice administered beta-cypermethrin, with significant protection given by co-administration of Vitamin E. The study is somewhat limited by the lack of discussion of general toxicity; however findings are consistent with those of Wang *et al* (2009) in indicating that testicular toxicity for beta-cypermethrin is secondary to oxidative stress rather than due to an endocrine MoA. Al Shaikh & Elfayoumi (2013) similarly report a protective effect of Vitamin E against reduced testis weight and biochemical changes induced by cypermethrin in the mouse. The study was performed with a commercial product and is therefore of limited reliability; however the consistency with other studies is notable. As with other studies, the value of Kumar *et al* (2004) is also limited due to the use of a non-physiological route of administration (intraperitoneal injection).

Testicular effects are reported for cypermethrin, beta-cypermethrin and alpha-cypermethrin; and this is in contrast to the different responses seen in the Hershberger assays, where Cypermethrin but not beta-cypermethrin induced reproductive organ weight changes. The nature of the histopathological findings, an association with general toxicity (including oxidative stress) and a number of studies demonstrating protective effects of anti-oxidants are clearly inconsistent with an endocrine MoA. Findings represent a more general toxic mechanism, and one that is not specific to the testes or male reproductive tract. While findings apparently consistent with an endocrine mode of action such as reduced circulating testosterone are reported by a number of authors, this effect could equally be induced by direct toxicity to the testes. Other findings such as increased LH / FSH levels and reduced weights of reproductive tract organs would also occur as a secondary effect of testicular toxicity. This direct effect on the testes is associated with general systemic toxicity (where reported) and is seen only at dose levels likely to result in general toxicity.

In order to investigate the potential to induce testicular toxicity /sperm toxicity with alpha-cypermethrin, a separate study has been performed and is further presented under CA 5.8.3/51.

Table 5.8.3-8: Summary of studies in male animals *in vivo*

Study	Result	Dose level	Comment
Wu et al., (2008)	Positive Hershberger (rat) Negative Hershberger (rat)	(neg. at 7-21) **≥63** mg/kg bw/d Cyp Neg at 6-18-54 mg/kg bw/d beta-Cyp	Same lab than Zhang et al., 2008

Studies in female animals i*n vivo*

Investigations with cypermethrin

Rat - 28 day

Report: CA 5.8.3/27
Fang L.Y. et al., 2012a
Effects of Cypermethrin on male reproductive system in adult rats
2013/1416880
Guidelines: none
GLP: no

Groups of 8-10 weaned female SD rats (age unspecified) were administered cypermethrin (95% purity) by gavage in 5 ml/kg bw peanut oil at dose levels of 0, 20, 40 or 80 mg/kg bw/d for 28 days. Weight gains in the cypermethrin-treated groups were lower than controls, but without a dose-response relationship. The rate of vaginal opening was increased, in the first week of treatment in the mid and high dose groups, and organ weights (ovarian, uterus and vagina) were increased with a clear dose-response relationship. However the informative value of this study is limited based on reporting deficiencies: Therate of vaginal opening is reported by week only and is no usual parameter and hardly interpretable. Standardized parameter for estrogenic/anti-estrogenic activity like the age at vaginal opening in combination with the body weight at the day of vaginal opening, length of cycle and age at first estrus after vaginal opening, percent of animals cycling and percent of animals cycling regularly are not given, and theage of animals was not specified. Mean and relative ovary, uterus and vagina weights were significantly higher in all treated groups; findings show a clear dose-response relationship.

Table 5.8.3-9: Time of vaginal opening

Group	Week 1	Week 2	Week 3
- control	37.5%	75.0%	100.0%
20 mg/kg bw/d	40.0%	70.0%	100.0%
40 mg/kg bw/d	62.5%	100.0%	100.0%
80 mg/kg bw/d	60.0%	90.0%	100.0%
+ control	100.0%	100.0%	100.0%

The results of this study therefore indicate some estrogenic effect of cypermethrin after dosing over 28 days *in vivo* but the reliability is somehow hampered based on deficits in methods and missing standard parameters.

Classification of study: supplemental information

Rat - 30 day

Grewal *et al* (2010) see CA 5.8.3/28 2010/1232204
Toxic Impacts of Cypermethrin on Behavior and Histology of Certain Tissues of Albino Rats
Toxicology International 17(2):94-98

Groups of male and female rats (strain unspecified) were gavaged with cypermethrin (in arachis oil; source and purity unspecified) at dose levels of 5 or 20 mg/kg bw/d for 30 days. The highest dose level was sufficient to cause a low rate of mortality; signs of toxicity were observed at both dose levels. Body weights are not reported. In female rats a complete loss of ovarian follicular cells and oocytes was seen at the highest dose level; accumulation of fluid was seen in the Graafian follicle. The study is considered to be of limited reliability in the absence of any specific reporting of systemic toxicity.

Classification of study: not futher considered

Rat – GD 7-21

Taxvig *et al* (2013) see CA 5.8.3/24 2013/1416882
In vitro - in vivo correlations for endocrine activity of a mixture of currently used pesticides
Toxicology & Applied Pharmacology 272: 757-766

In the *in vivo* phase of this study, groups of 12 female mated Wistar rats were gavaged with mixtures of 3 (Mix3) or "3 plus additional 2" (Mix5) pesticides (including cypermethrin as one of Mix3 and Mix5) on Gestation Days 7-21. Mixtures included compounds administered in equal proportions at single compound dose levels of 1, 3 or 10 mg/kg bw/d. No effects were seen on maternal bodyweight or adjusted bodyweight for Mix3. Plasma hormone levels in dams treated with Mix3 were unaffected for estradiol, progesterone, T3 and T4 at GD21. Litter parameters were unaffected by treatment and anogenital distance was comparable in all groups. Testosterone levels in placentas were unaffected in the Mix3 up to the highest dose as well as testiculare hormone levels in pup on GD21. No histopathological changes of testes were seen. Cypermethrin and its metabolite M310I011 were detected in the amniotic fluid from rats of all treated groups. The authors conclude that this study provides evidence that all single pesticides are able to affect steroidogenesis in vitro, but only the Mix5 exerted endocrine activity in vivo in dams and female fetuses, but that this is due to terbuthylazine. In conclusion, doses up to 10 mg/kg bw cypermethrin were not able to affect endocrine system in Wistar rats in vivo.

Classification of study: supplemental information

Investigations with alpha-cypermethrin

Rat and Mice – uterotrophic assay

Liang *et al* (2005) see CA 5.8.3/15 2005/1043340
A study on the estrogenic effects of alpha-and theta-cypermethrin
Chin Occup Med. August 2005, Vol 32, No.4, 25-26

In an uterotrophic assay performed in groups of eight ovariectomised female SD rats, no effect on uterus weight was seen in response to subcutaneous injection of alpha-cypermethrin (14 mg/kg bw/d; no purity given) or theta-cypermethrin (520 mg/kg bw/d; no purity given) on five consecutive days. A suitable response to the positive control substance (100 µg/kg bw β-oestradiol) was seen in this assay.
In an uterotrophic assay performed in groups of eight intact female NH mice, no effect on uterus weight was seen in response to subcutaneous injection of alpha-cypermethrin (3 mg/kg bw/d) or theta-cypermethrin (10 mg/kg bw/d) on three consecutive days. A suitable response to the positive control substance (100 µg/kg bw β-oestradiol) was seen in this assay.
The reporting of the study is limited, no data on bodyweight or organweight are given. Taken the results of this study as given, this would indicate no oestrogenic effect of alpha-cypermethrin and theta-cypermethrin after s.c. injection in rats and mice.

Classification of study: supplemental information

Investigations with Metabolites

Rat - pubertal female assay with metabolites

Laffin *et al* (2010) see CA 5.8.3/16 2010/1232196
The pyrethroid metabolites M310I011 and M310I024 do not exhibit estrogenic activity in the MCF-7 human breast carcinoma cell line or Sprague–Dawley rats
Toxicology 267: 39-44

In a pubertal assay, groups of 5-8 immature female rats were gavaged with the pyrethroid metabolites M310I011 and M310I024 (no purities given) at dose levels of 0, 1, 5 or 10 mg/kg bw/d from weaning until detection of the onset of puberty. Rats were subsequently assessed daily for first dioestrus. The authors do not report any statistically significant effect of exposure to either metabolite on uterine wet weight; however slightly higher absolute (1.6 times control) and relative (1.4 times control) uterus weights were seen in rats administered 10 mg/kg bw/d M310I011. No significant effect was seen of either metabolite on the attainment of puberty or sexual maturity.

Classification of study: supplemental information

Summary of studies in female animals *in vivo*

Li *et al* (2008) report a positive response in a female pubertal assay at dose levels of 20, 40 and 80 mg/kg bw/d cypermethrin. A trend to earlier attainment of puberty is seen from 40 mg/kg bw onwards; however the value of the study is limited by reporting and by relatively high doses used which are considered to induce general toxicity. A clear and dose-related increase in ovary, uterus and vaginal weights is seen at all dose levels in this study. The clear response seen in this study is somewhat unexpected given the absence of a clear effect of cypermethrin in oestrogenicity assays *in vitro*; however the response may be attributable to the generation of higher levels of metabolites *in vivo*. The study of Laffin *et al* (2010) indicates a weak oestrogenic effect of the metabolite M310I011; it is notable that the dose levels used in this study are lower than the cypermethrin dose levels used by Li *et al* (2008).
Liang et al (2005) reports negative results in the uterotrophic assays performed in the rat and mouse for alpha-cypermethrin (14 and 3 mg/kg bw/d respectively) and theta-cypermethrin (520 and 10 mg/kg bw/d respectively). This study used administration by subcutaneous injection. The study of Taxvig *et al* (20008) does not show any hormonal change in dams and fetuses related to cypermethrin doses during pregnancy of up to 10 mg/kg bw although either cypermethrin and its metabolite M310I011 are detectable at all dose levels in the amniotic fluid at GD21. Grewal *et al* (2010) does not provide any relevant information.
Although evidence for the oestrogenicity of cypermethrin *in vitro* is inconsistent, based on information on the relative oestrogenic activity of cypermethrin metabolites, the positive response for cypermethrin in vivo reported by Li *et al* (2008) is likely to be due (at least in part) to its metabolites formed after gavage of high doses, like for example via M310I024. Furthermore *in vitro* data indicate that the oestrogenicity of permethrin is increased by the formation of 4-HO cis-permethrin and more relevant by the formation of 4-HO-PBAlc. The metabolism of *cis*-isomers is less than that of *trans*-isomers, and for alpha-cypermethrin no formation of 4-HO cis-permethrin or 4-HO-PBAlc was observed in vivo. In this respect the positive oestrogenic responses with cypermethrin described by Li *et al* (2008) are considered less relevant for alpha-cypermethrin. This is supported by Liang *et al* (2005) based on no uterotrophic effect for alpha-cypermethrin in the rat and mouse respectively. However the dose levels are lower than those used for cypermethrin by Li *et al* (2008) (20-80 mg/kg bw/d), however these may have been limited by the higher toxicity of the cis-isomers.

In conclusion, no endocrine related effects are reported for alpha-cypermethrin or are considered relevant under consideration of the metabolic turnover in females in vivo.

Table 5.8.3-10: Overview of studies in female animals *in vivo*

Study	Result	Dose level	Comment
Li *et al*, 2008	Earlier puberty Increased ovary, uterus & vagina weights	Rat ≥20 mg/kg bw/d oral Cypermethrin	-
Laffin *et al*, 2010	No effects on puberty Slightly increased uterus weight	Rat ≤10 mg/kg bw/d oral 3-PBA	-
Liang *et al*, 2005	No uterotrophic effect	Rat / mouse alpha-cypermethrin 14 / 3 mg/kg bw/d theta-cypermethrin 520 / 10 mg/kg bw/d	-
Taxvig *et al*, 2013	Exposure of fetuses during pregnancy to cypermethrin and 3-PBA, no hormonal changes, no histopathological testis changes	Rat ≤10 mg/kg bw/d (GD7-21)(mixture study)	cypermethrin administered as a mixture component
Grewal *et al*, 2010	Loss of ovarian follicle cells and oocytes	Rat ≤20 mg/kg bw/d oral Cypermethrin	Limited reliability

Other studies

Gene expression and regulation studies

Report: CA 5.8.3/44
Pan C. et al., 2012a
Effects of Cypermethrin on the ligand-independent interaction between androgen receptor and steroid receptor coactivator-1
2012/1367063
Guidelines: none
GLP: no

The authors report the use of a two-hybrid assay to investigate the effects of cypermethrin (99% pure) on the interaction between the androgen receptor N-terminal and C-terminal domains using a CAT reporter gene assay in CV-1 cells. Recruitment of the steroid receptor coactivator-1 (SRC-1) was shown to be mediated primarily by the N-terminus of the androgen receptor. Exposure to cypermethrin at a concentration of 10^{-5} M was shown to significantly inhibit the interaction of androgen receptor activation function-1 (AF-1) on the N-terminal domain and SRC-1. The authors postulate that the interaction with cypermethrin may down-regulate expression of androgen receptor-dependent genes.

Classification of study: supplemental information

Report: CA 5.8.3/45
Pan C. et al., 2013a
Anti-androgen effects of the pyrethroid pesticide Cypermethrin on interactions of androgen receptor with corepressors
2013/1416881
Guidelines: none
GLP: no

In a further study by the same authors using mammalian two-hybrid assays, cypermethrin (995 pure) at a concentration of 10^{-5} M was shown to significantly enhance the interaction between the androgen receptor and its co-repressors SMRT and NCoR. These repressors are known to play key roles in the transcriptional repression of the androgen receptor. The authors propose that this interaction is a novel mechanism for the anti-androgenic activity of cypermethrin.

Classification of study: supplemental information

Report: CA 5.8.3/46
Hu J.-x. et al., 2011b
Anti-androgen effects of Cypermethrin on the amino- and carboxyl-terminal interaction of the androgen receptor
2012/1367064
Guidelines: none
GLP: no

This study investigated the potential of cypermethrin (99% pure) to interact with specific domains (the carboxy-terminal ligand-binding domain and the amino-terminal domain) of the androgen receptor using a mammalian two-hybrid assay. Interaction of these two domains is required for full transcription potential of the receptor and agonists such as DHT are known to induce this interaction. Co-transfected CV-1 cells were exposed to concentrations of cypermethrin for 24 hours alone or in the presence of the androgen agonist DHT. Exposure of cells to cypermethrin at concentrations of 10^{-7} to 10^{-5} M did not induce expression of the CAT reporter gene. Exposure to cypermethrin at a concentration of 10^{-5} M (but not 10^{-6} or 10^{-7} M) in the presence of DHT (concentrations of 10^{-7} M and 10^{-8} M) was shown to significantly reduce the induced expression of the reporter gene. Results are presented graphically and do not appear to be of great magnitude (a relative CAT activity of approximately 6 compared to approximately 7 in controls at both DHT concentrations). Exposure to the known androgen receptor antagonist nilutamide was shown to significantly reduce DHT-induced expression of the reporter gene at the concentrations investigated (10-7 to 10^{-5} M) and to a much greater degree compared to cypermethrin (relative CAT activity of approximately 1.5 compared to approximately 7 in controls at 10^{-8} M DHT). The authors suggest that cypermethrin exerts an antagonistic effect on the androgen receptor through interference with the interaction between the receptor and ligands such as DHT.

Classification of study: supplemental information

Summary: **The results of these studies indicate that the anti-androgenic effect of cypermethrin seen in studies *in vitro* may not be due to direct binding to the androgen receptor. In this respect, it is notable that the studies of androgenicity *in vitro* are transcriptional activation assays and therefore do not directly measure receptor binding.**

Effects on sperm in vitro

Report: CA 5.8.3/47
Song L. et al., 2008a
Effects of Fenvalerate and Cypermethrin on rat sperm motility patterns in vitro as measured by computer-assisted sperm analysis
2008/1102216
Guidelines: none
GLP: no

The effects of cypermethrin (99.05% purity) on rat sperm mobility were assessed *in vitro*. Sperm suspensions were incubated with cypermethrin at concentrations of 1, 4, 16 or 64 µM for 1, 2, or 4 hours and motility assessed using an automated system. Following exposure for 1 hour, sperm curvilinear velocity was unaffected by treatment. Average path velocity was significantly increased at 64 µM; straightline velocity, beat cross frequency, linearity and straightness were all significantly reduced at ≥ 4 µM; the amplitude of lateral head displacement was significantly reduced at 64 µM only. Following exposure for 2 hours, curvilinear velocity and average path velocity were unaffected by treatment. Straightline velocity, beat cross frequency, linearity and straightness were significantly reduced at ≥ 4 µM; linearity was also significantly reduced at 1 µM. The amplitude of lateral head displacement was unaffected by treatment. Following exposure for 4 hours, curvilinear velocity was significantly reduced at ≥16 µM. Average path velocity was unaffected by treatment. Straightline velocity, beat cross frequency, linearity and straightness were significantly reduced at ≥16 µM; the amplitude of lateral head displacement was unaffected by treatment.

Classification of study: supplemental information

Report: CA 5.8.3/48
Yuan C. et al., 2009a
Effects of Permethrin, Cypermethrin and 3-Phenoxybenzoic acid on rat sperm motility in vitro evaluated with computer-assisted sperm analysis
2010/1232201
Guidelines: none
GLP: no

The effects of cypermethrin and its metabolite M310I011 on sperm motility were assessed *in vitro*. Epididymal sperm from male SD rats was exposed to cypermethrin (>99% purity) or M310I011 at concentrations of 1, 4, 16 or 64 µM for 1, 2 or 4 hours; sperm parameters were measured using an automated system. Exposure to cypermethrin concentrations of ≥4 µM for 1 or 2 hours resulted in significantly decreased straight-line velocity, linearity, beat cross frequency and straightness. After exposure for 4 hours, effects were only seen at ≥16 µM. At the highest concentration, a number of samples showed no motile sperm. In contrast to cypermethrin, the metabolite M310I011 was shown not to have any effects on sperm motility parameters.

Classification of study: supplemental information

Summary: Effects on sperm motility *in vitro* are shown by the studies of Song *et al* (2008) and Yuan *et al* (2010) for cypermethrin. Studies used relatively high concentrations of questionable physiological relevance.
However, the effects seen are not indicative of an endocrine MoA and are more likely to be a consequence of the known effects of cypermethrin on sodium channels.

Report:	CA 5.8.3/49 [redacted] 2014 BAS 310 I (Alphacypermethrin) 15-Day Intact Adult Male Rat Assay Administration by Gavage 2014/1275120
Guidelines:	U.S. EPA Office of Science Coordination and Policy, Washington D.C., U.S.A; Validation of 15-day intact adult male rat assay as a potential screen in the endocrine disruptor screening program tier-1 battery, 29 Aug 2007
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)
Remark:	~~The study report is at the time of dossier submission not finalized with regard to QAU-check and will therefore be delivered at a later stage.~~ The range finder used for dose setting is provided under KCA 5.8.3/51 2014/1289319.

Executive Summary
The aim of this study was to determine the toxicological profile of alpha-cypermethrin including the target organs and the "no observed adverse effect level" in the 15 days adult male rat assay after oral administration by gavage in corn oil. In this type of study special attention is given to selected male reproductive organs and sperm parameters.
The test item was administered to groups of 15 male adult Wistar rats for 15 days at doses of 2.0, 3.5, and 6.6 mg/kg bw/day. No treatment related clinical signs of toxicity and no mortalities were observed. No adverse effects on body weight were observed. Furthermore, no adverse effects on food consumption and body weight gain were observed. When compared to the control group the mean absolute and relative organ weights were not significantly changed. No test item related macroscopic lesions were recorded. Sperm motility and morphology as well as sperm head counts in testes or in cauda epididymidis were not influenced by the test item. Furthermore, no significant differences in androgen receptor staining could be detected. In conclusion, a NOAEL of 6.6 mg/kg bw/day can be derived, as no adverse findings were observed after treatment with 6.6 mg/kg bw/day (highest dose tested).
(DocID 2014/1275120)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:	BAS 310 I (Alphacypermethrin)
Description:	solid / white
Lot/Batch #:	PMAM000622
Purity:	99.2%
Stability of test compound:	The test substance was stable under storage conditions over the test period as guaranteed by the sponsor (expiry date 12 Dec 2015)

2. Vehicle: corn oil (1 mL/kg)

3. Test animals:

Species:	Rat
Strain:	Crl:WI(Han)
Sex:	Male
Age:	70 ± 1 days
Weight at dosing (range):	265.1 - 306.2 g
Source:	Charles River Laboratories, Research Models and Services, Germany GmbH, Sulzfeld, Germany
Acclimation period:	at least 7 days
Diet:	Ground Kliba maintenance diet mouse/rat "GLP", Provimi Kliba SA, Kaiseraugst, Switzerland, ad libitum
Water:	water, ad libitum
Housing:	group housing (maximum 4 per cage) in polysulfonate (H-Temp) cages type 2000P with dust-free wooden bedding
Environmental conditions:	
Temperature:	20 - 24°C
Humidity:	30 - 70%
Air changes:	15 per hour
Photo period:	12 h light / 12 h dark (06:00 - 18:00 / 18:00 - 06:00)

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 26-Aug-2014 – 13-Jan-2015
(In life dates: 02/03-Sep-2014 (start of administration) to 17/18-Sep-2014 (necropsy)

2. Animal assignment and treatment:

Range finding study

The test item was administered to groups of 3 male Wistar rats for 14 days at dose levels of 0 (vehicle control; test group 0), 10 mg/kg body weight/day (test group 1) and 25 mg/kg body weight/day (test group 2) by gavage. Corn oil (1 ml/kg) served as vehicle.

Main study

The animals were distributed into 4 test groups of each 15 animals. Each test group was subdivided into Section A and B including 8 and 7 animals, respectively. The animals were treated with the test item for 15 days at daily doses of 2, 3.5, 6.6 mg/kg bw or with the vehicle alone with an administration volume of 1 mL/kg bw.

Table 5.8.3-11: Overview on test groups and applied doses

Test group	Dose (mg/kg bw/d)[b]	Concentration (g/100 mL)	No. of animals	Section	Animal No.	Cage No.
0	0	0.0	15	A	1 – 4 5 – 8	1 2
				B	9 – 12 13 – 15	3 4
1	2.0	0.2	15	A	16 – 19 20 – 23	5 6
				B	24 – 27 28 – 30	7 8
2	3.5	0.35	15	A	31 – 34 35 – 38	9 10
				B	39 – 42 43 – 45	11 12
3	6.6	0.66	15	A	46 – 49 50 – 53	13 14
				B	54 – 57 58 – 60	15 16

3. Test substance preparation and analysis:

For the test substance preparations, the specific amount of test substance will be weighed and filled up with Corn Oil Ph. Up to the desired volume, subsequently released manually.
The stability of the test substance in corn oil at room temperature over a period of 7 days had been verified during the study (Project No.: 01Y0265/01Y012). Homogeneity of BAS 310 I (Alphacypermethrin) in the diet was performed in the highest and lowest concentration. Additionally, concentration control was performed in all concentrations at the beginning of the administration period.

4. Statistics:

Means and standard deviations (S.D.) of each test group were calculated for several parameters. In addition, the following statistical analyses were carried out:

Parameter	Statistical test	Markers in the tables	References
Clinical examinations Body weight and body weight change	A comparison of each group with the control group was performed using DUNNETT's test (two-sided) for the hypothesis of equal means	* for $p \leq 0.05$ ** for $p \leq 0.01$	DUNNETT, C.W. (1955): A multiple comparison procedure for comparing several treatments with a control. JASA, Vol. 50, 1096-1121 DUNNETT, C.W. (1964). New tables for multiple comparisons with a control. Biometrics, Vol. 20, 482-491

Feces, rearing, grip strength forelimbs, grip strength hindlimbs, foot-splay test, motor activity	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON test (two-sided) for the equal medians	* for $p \leq 0.05$ ** for $p \leq 0.01$	SIEGEL, S. (1956): Non-parametric statistics for the behavioural sciences. McGraw-Hill New York
<u>Pathology</u> Weight parameters Cell count	Non-parametric one-way analysis using KRUSKAL-WALLIS test (two-sided). If the resulting p-value was equal or less than 0.05, a pairwise comparison of each dose group with the control group was performed using WILCOXON-test (two-sided) for the equal medians WILCOXON-test (two-sided)	* for $p \leq 0.05$ ** for $p \leq 0.01$	HETTMANNSPERGER, T.P. (1984): Statistical Inference based on Ranks, John Wiley & Sons New York, 132-140. International Mathematical and Statistical Libraries, Inc., 2500 Park West Tower One, Houston, Texas 77042-3020, USA, nakl-1 - nakl-3 MILLER, R.G. (1981): Simultaneous Statistical Inference, Springer-Verlag New York Inc., 165-167 NIJENHUIS, A. and S.W. WILF (1978): Combinatorial Algorithms, Academic Press, New York, 32-33
<u>Clinical pathology</u> Sperm analysis parameters	Pairwise comparison of each dose group with the control group using the WILCOXON-test (one-sided) with Bonferroni-Holm adjustment for the hypothesis of equal medians; If only control and one dose group are measured, WILCOXON-test (one-sided) without adjustment were used. For the percentage of abnormal sperms (ABNORMAL6_C) values <6% were set to 6% (cut off 6%)	* for $p \leq 0.05$ ** for $p \leq 0.01$	HOLM, S. (1979): A Simple Sequentially Rejective Multiple Test Procedure. Scand. J. Statist. 6, 65-70

C. METHODS

1. Observations:

Range finding study

Body weight was determined before the start of the administration period in order to randomize the animals and on study days 0, 3, 7, 10 and 14. Food consumption and water consumption were determined on study days 3, 7, 10 and 14. The animals were checked daily for any abnormal clinically signs before the administration as well as within 2 hours and within 5 hours after the administration. Because the animals of test group 2 (25 mg/kg bw/d) were sacrificed moribund on study day 0 no food consumption and water consumption could be determined.
The animals were sacrificed using CO_2, necropsied and assessed by gross pathology. Animals which died intercurrently were sacrificed in a moribund condition, were sacrificed without further examinations.

Main study

Mortality

A check for moribund and dead animals was made twice daily from Mondays to Fridays and once daily on Saturdays, Sundays and public holidays. If animals were in a moribund state, they were sacrificed and necropsied.

Clinical signs

During the recovery period the animals were checked once daily for any abnormal clinical signs. Abnormalities and changes were documented for each animal.

Detailed clinical observations

All animals were subjected to detailed clinical observations (DCO) outside their cages once before the beginning of the administration period (day 0) and subsequently once a week. For observation, the rats were removed from their cages and placed in a standard arena (50×37.5×25 cm). The scope of examinations and the scoring of the findings that were observed were based on the current index of findings in PDS ToxData® software and include but were not limited to the following parameters listed:

1. Abnormal behavior in handling
2. Fur
3. Skin
4. Posture
5. Salivation
6. Respiration
7. Activity/arousal level
8. Tremors
9. Convulsions
10. Abnormal movements
11. Gait abnormalities
12. Lacrimation
13. Palpebral closure
14. Exophthalmos
15. Assessment of the feces discharged during the examination (appearance/consistency)
16. Assessment of the urine discharged during the examination
17. Pupil size

2. Body weight and body weight change:
Body weight was determined before the start of the administration period in order to randomize the rats. During the administration period the body weight was determined on study day 0 (start of administration period) and thereafter at weekly intervals. The difference between the body weight on the respective day of weighing and the body weight on day 0 was calculated as body weight change.

3. Food and water consumption:
Food consumption was determined weekly (as representative value over 3 days) and calculated as mean food consumption in grams per rat and day. Drinking water consumption was monitored by daily visual inspection of the water bottles for any changes in volume.

3. Clinical pathology:
Blood samples were taken from fasted animals by puncturing the retrobulbar venous plexus under Isoflurane anesthesia. Blood sampling and examination were carried out in a randomized sequence (the list of randomization instructions will be compiled with a computer).

The following parameters have been examined:

Hormones:
Serum samples were taken and frozen at -80°C for storage. Measurement of FSH, LH and Testosterone should only have been carried out if there was an indication for effects on organ weights and/or sperm parameters. The determination should also have been triggered based upon potential alterations of histopathology.

Sperm parameters:
Immediately after necropsy and organ weight determination the right testis and cauda epididymidis were taken from all male animals.

The following parameters were determined:

Parameter	Unit	Method	References
Sperm motility	%	microscopic evaluation	Slott, Suarez and Perreault, "Rat sperm motility analysis: Methodological considerations" in: "Reproductive Toxicology", Vol 5, pp. 449-458 (1991)
Sperm morphology	%	vital staining with eosin; microscopic evaluation	M.H. Feuston, K.R. Bodnar, S.L. Kerstetter, C.P. Grink, M.J. Belcak and E.J. Singer, "Reproductive
Sperm head count (cauda epididymis)	Mio/g cauda epididymis	microscopic evaluation with MAKLER chamber after homogenization	Toxicity of 2-Methoxyethanol Applied Dermally to Occluded and Nonoccluded Sites in Male Rats" in:
Sperm head count (testis)	Mio/g testis	microscopic evaluation with MAKLER chamber after homogenization	Toxicology and applied Pharmacology 100, 145-161 (1989) (Laboratory modification)

Sperm motility examinations were carried out in a randomized sequence. Sperm head count (testis and cauda epididymis) and morphology was evaluated in all animals.

The right testis and right cauda epididymidis were deep frozen at -20°C until evaluation.

4. Pathology and histopathology:

Necropsy

The animals were sacrificed by decapitation under isoflurane anesthesia. The exsanguinated animals were necropsied and assessed by gross pathology. Animals which die intercurrently or were sacrificied in a moribund state were necropsied as soon as possible after their death and assessed by gross pathology.

Organ weights

The following weights were determined in all animals sacrificed on schedule:

1. Anesthetized animals
2. Adrenal glands
3. Brain
4. Cauda epididymis
5. Epididymides
6. Heart
7. Kidneys
8. Liver
9. Pituitary gland
10. Prostate
11. Seminal vesicles with coagulating glands
12. Spleen
13. Testes
14. Thyroid glands

Organ/tissue fixation

The following organs/tissue specimens were carefully removed, processed histotechnically and examined.
The following organs or tissues were fixed in 4% formaldehyde solution or in modified Davidson´s solution:

1. All gross lesions	26. Ovaries
2. Adrenal glands	27. Oviducts
3. Aorta	28. Pancreas
4. Bone marrow (femur)	29. Parathyroid glands
5. Brain	30. Pharynx
6. Cecum	31. Pituitary gland
7. Coagulating gland	32. Prostate
8. Colon	33. Rectum
9. Duodenum	34. Salivary glands (mandibular and sublingual glands)
10. Epididymis, left	
11. Esophagus	35. Sciatic nerve
12. Extraorbital lacrimal glands	36. Seminal vesicles
13. Eyes with optic nerve (modified Davidson's solution)	37. Skeletal muscle
	38. Skin
14. Femur with knee joint	39. Spinal cord (cervical, thoracic and lumbar cord)
15. Harderian glands	
16. Heart	40. Spleen
17. Ileum	41. Sternum with marrow
18. Jejunum (with Peyer's patches)	42. Stomach (forestomach and glandular stomach)
19. Kidneys	
20. Larynx	43. Testis, left (modified Davidson's solution)
21. Liver	
22. Lungs	44. Thymus
23. Lymph nodes (mesenteric and axillary lymph nodes)	45. Thyroid glands
	46. Trachea
24. Mammary gland (male)	47. Urinary bladder
25. Nose (nasal cavity)	

Histopathology

Fixation was followed by histotechnical and immunohistological processing, examination by light microscopy and assessment of findings according to the table below.

Organs	**Test group**			
	0	**1**	**2**	**3**
1. All gross lesions	A2	A2	A2	A2
2. Adrenal glands	A1			A1
3. Epididymis, left	A1			A1
4. Pituitary gland	A1			A1
5. Prostate	A1			A1
6. Seminal vesicles with coagulating gland	A1			A1
7. Testis, left	A1/I1	I1*	I1*	A1/I1

A = hematoxylin and eosin (H&E) stain
I = immunohistology (androgen receptor)
* = not evaluated
1 = all animals/test group
2 = all animals affected/test group
Prostate served as positive control for androgen receptor staining.

The organs were trimmed according to the "Revised guides for organ sampling and trimming in rats and mice". (Ruehl-Fehlert et al., 2003; Kittel et al., 2004; Morawietz et al., 2004).

A correlation between gross lesions and histopathological findings was attempted. After completion of the histopathological assessment by the study pathologist an internal peer review was performed. Results presented in this report reflect the consensus opinion of the study pathologist and the peer review pathologist.

Immunohistology staining
Sections were dewaxed with xylene and graded ethanol, the slides were then washed and kept in deionized water until antigen retrieval. Antigen retrieval was performed with 0.2 mol boric acid, pH 7.0 for 10 minutes at 120°C in a pressure cooker. Sections were cooled in deionized water. Endogenous peroxidase was then blocked with 6% hydrogen peroxide. Sections were rinsed in deionized water and incubated with the primary antibody (androgen receptor N-20, 1:600; Santa Cruz Biotechnology Inc., Heidelberg, Germany) for 2 hours at room temperature. Sections were then rinsed in wash buffer, and the label enzyme complex (polymerfluid, ZYTOMED Systems GmbH, Berlin, Germany) was applied for 30 minutes. Sections were then rinsed in wash buffer before the chromogen DAB (ZYTOMED Systems GmbH, Berlin, Germany) was applied for 3 minutes. Slides were counterstained with Mayer's hematoxylin and coverslipped with Pertex.
For evaluation and assessment of androgen staining, the immunostained slides of all animals were digitalized using a Hamamatsu NanoZoomer (Slide Scanner). Resulting images were viewed and processed with the Hamamatsu NanoZoomer viewer software (NDP.view.2.3.10).

Evaluation and assessment of testis tubule perimeter as well as number of Sertoli cells positively stained for androgen receptor
Beginning at the top left, the digitalized image was searched for the presence of stage VII, VIII, and IX tubuli, respectively. Tubuli were staged according to the criteria in Russell et al. (1990). Once a tubule of an appropriate stage was found, the perimeter of this tubule was measured using the freehand form feature of the software and exported as a jpg-file. Sertoli cells in this tubule were differentiated and detected on the base of their location within this tubule and their shape and size. Sertoli cells positively stained for androgen receptor (brown DAB staining on nuclei) were counted in each tubule. The number of positive Sertoli cells per tubule perimeter was calculated as positive cells divided by the length of the perimeter. In each image it was attempted to find at least 5 tubuli of each of the 3 stages of interest. This was possible in slides of most animals. On the whole, approximately 100 tubuli per group and stage were evaluated using slides from all 15 animals per test group.

II. RESULTS AND DISCUSSION

RANGE FINDING STUDY

Mortality
All animals of test group 2 (25 mg/kg bw/d) were sacrificed moribund on study day 0 between 2-5 h after administration. No other animal died prematurely or were sacrificed moribund in the present study.

Clinical examinations
Tonic-clonic convulsions, tremors, piloerection, poor general condition, salivation and ploughed nose-first into bedding were observed in all animals of test group 2 (25 mg/kg bw/d). Additionally, nasal discharge and rolling convulsions were observed in one of three animals of test group 2 (25 mg/kg bw/d). The high dose group was thus discontinued as severe grades of tremors and further neuriotoxic effects were observed at the day of dosing between hour 2 and 5.
All animals of test group 1 (10 mg/kg bw/d) showed unsteady gait, piloerection, tremors, poor general condition, salivation and ploughed nose-first into bedding. Additionally, ataxia, splayed limbs, abdominal position, hyperexcitability and excessive grooming was observed in animal No. 6 of test group 1 (10 mg/kg bw). Two animals (No. 5 and 6) did not recover completely from administration at study day 1 and showed poor general condition ahead of the substance administration at study day 2. Body weight loss or stagnation were obvious in all animals of test group 1 (10 mg/kg bw). Therefore the dose was reduced from 10 to 5 mg/kg bw/d from study day 2 onwards. Animal No. 6 of test group 1, which showed ataxia, tremors, splayed hindlimbs, unsteady gait, salivation and poor general state after the first administration of 5 mg/kg bw on study day 2, received no test substance preparation on study days 3, 4 and 5. Animal No. 4 and 5 showed tendency of recovery under administration of 5 mg/kg bw and no test substance-related adverse findings were observed from study day 4 onwards.

Food consumption
No significantly changes of food consumption could be observed. On study day 3 food consumption of test group 1 (10 as well as 5 mg/kg bw/d) was decreased by 25% compared to the control group.

Body weight data
Body weight loss was observed in test group 1 (10 as well as 5 mg/kg bw/d) on study day 3. Body weight change was significantly decreased on study day 10 by 45% compared to the control group.

Table 5.8.3-12: Mean body weight of rats administered alpha-cypermethrin

Based on the results of the range finding study a dose slightly above 5 mg/kg bw and below 10 mg/kg bw was considered adequate as high dose in the main study.

Cypermethrin and beta-cypermethrin are reported in the open literature to show effects in the 15 day adult male rat assay, which is considered a Level 4 in vivo Screening Assay in the Guidance on Identifying Endocrine Disrupting Effects (ECETOC Technical Report No. 106). The hypothesis is presented that cypermethrin and beta-cypermethrin act as anti-androgens in the rat by reducing androgen receptor expression and thereby adversely affects spermatogenesis and testosterone synthesis (see CA 5.8.3/41 2010/1232198, CA5.8.3/26 2011/1296731 and CA5.8.3/27 2013/1416880). The table Table 5.8.3-14 summarizes the reported effects.
The dose proposal for the main part of the 15day adult rat assay was based on the alpha-cypermethrin equivalent dose considering the CIS-2 portion in cypermethrin and beta-cypermethrin as presented in the bridging statement (see KCA 5.0).

Table 5.8.3-14: Lowest observed effect levels seen in the 15 day rat male assay reported in the open literature and the approximate alpha-cypermethrin portion

Reference	Substance Dose levels purity	Organ weigth	Testicular histology	Sperm-parameters	Hormon (T, LH, FSH)	AR-staining	CIS 2 portion
KCA 5.8.3/26	Cypermethrin 0-6.25-12.5-25-50 Purity: 97.53%	**25**	**6.25**	50	T: 50 FSH: 50 LH: 50	**12.5**	22%
KCA 5.8.3/27	Cypermethrin 0-7.5-15-30-60 Purity: 98%	>60	7.5	**30**	**T: 30** FSH: 60 LH: >60	n.a.	22%
KCA 5.8.3/41	Beta-cypermethrin 0-15-30 Purity: >95%	>30	n.a.	**15**	n.a.	**15**	40%
alpha-cypermethrin equiv. dose based on cypermethrin data		25*0.22= 5.5	6.25*0.22 = 1.4	30*0.22= 6.6	30*0.22 = 6.6	12.5*0.22 = 2.75	
alpha-cypermethrin equiv. dose based on beta-cypermethrin data				15*0.4= 6		15*0.4= 6	

n.a.: not applicable as the parameter was not investigated in the study not applicable as the parameter was not investigated in the study
n.d.: Study did not investigate this parameter
T: Testosterone; LH: Luteinizing hormone; FSH:follicle-stimulating hormone;

Based on this conversion into alpha-cypermethrin equivalent dose it was considered adequate to use 2.0, 3.5 and 6.6 mg/kg bw in the main study because:

a) In case that the portion of alpha-cypermethrin is responsible for the reported effects, one would expect histopathological changes in the testes at a dose level of 1.4 mg/kg bw/day, followed by changes in AR distribution at a dose level of 2.75 or at least 6 mg/kg bw followed by effects on sperm parameters and hormone level at a dose of 6 mg/kg bw or at least 6.6 mg/kg bw
b) it was considered reasonable to take the dose levels 2.0 and 3.5 mg/kg bw/day into account which are currently used for ADI and AOEL reference dose setting.

The change from SD to Wistar rats is not considered to reduce the sensitivity of the study because:

a) the Wistar strain Crl:WI(Han) has shown sensitivity to endocrine related effects in several studies performed in house
b) the basis for recommending SD rats for this type of study as done in the "Integrated summary report for validation of 15-day intact adult male rat assay as a potential screeni in the endocrine disruptor screening program Tier-1 Battery" (online available under http://www.epa.gov/endo/pubs/isr_adultmalerat.pdf) **is not sensitivity** but the availability of this rat strain and its frequent use as animal model of choice for determining general toxicological effects in US-laboratories and the available historical control data
c) according to the "Reviewer`s appendix to the white paper on species/stock/strain in endocrine disruptor assays" published in 2004 by the EPA (online available under http://www.epa.gov/endo/pubs/edt02wdisc.pdf) an unselected Wistar outbred such as the Wistar Hannover which has a moderate litter size and moderate production index might be preferable since it is likely to be more representative of humans that have not been selected long-term for high fecundity. Furthermore, Wistar rats are more sensitive than SD/CD rats to decreases in testes and seminal vesicle weights and testosterone levels by DES, inhibition of sperm count and daily sperm production by BPA, and inhibition of spermatogenesis by lead.

MAIN STUDY

A. TEST SUBSTANCE ANALYSES

Stability analyses
The stability of BAS 310 I (Alphacypermethrin) in corn oil at room temperature for a period of 7 days was proven before the start of the study.

Homogeneity control analyses
Considering the low relative standard deviation in the homogeneity analysis, it can be concluded that BAS 310 I (Alphacypermethrin) was distributed homogeneously in corn oil.

Concentration control analyses
The mean values (low, mid and high doses) of BAS 310 I (Alphacypermethrin) in corn oil were found to be in the range of 90-110% of the nominal concentrations.
These results demonstrated the correctness of the concentrations of BAS 310 I (Alphacypermethrin) in corn oil.

B. OBSERVATIONS

1. Clinical signs of toxicity

No treatment related clinical signs of toxicity were reported.

2. Mortality

No animal died prematurely in the present study.

C. BODY WEIGHT AND BODY WEIGHT GAIN

No test substance-related differences with regard to the mean body weights and body weight change values were noted for male animals of test groups 1-3 (2.0, 3.5 and 6.6 mg/kg bw/day). Body weight increased throughout the study period in any dose group and no significant differences were observed between treated and control group animals. Body weight gains from day 0 - 7 and 0 – 14 were slightly lower in the treated groups without being statistically significant ranging from 2.5% to 12.2%. No dose-dependency of the body weight gain changes was observed and therefore the effects are considered incidental.

Table 5.8.3-15: Mean body weight of rats administered alpha-cypermethrin

Sex	**Males**

D. FOOD CONSUMPTION

No test substance-related, adverse findings were observed. All recorded values were within the biological range typical for this strain of rats.

Table 5.8.3-17: Food consumption of rats administered alpha-cypermethrin

Sex	**Males**			
Test-item	Control	Alpha-cypermethrin		
Dose level [mg/kg bw]	0	2.0	3.5	6.6
Mean food consumption [g]

E. NECROPSY

1. Organ weight

When compared to the control group (set to 100%) the mean absolute and relative (to final bw) organ weights were not significantly changed (see Table 5.8.3-18 and Table 5.8.3-19). A slight reduction of absolute and relative prostate and seminal vesicle weight was observed being not statistically significant.

Table 5.8.3-18: Mean absolute organ weights of rats administered alpha-cypermethrin

Sex	**Males**			
Test-item	Control	Alpha-cypermethrin		
Dose level [mg/kg bw]	0	2.0	3.5	6.6
Mean absolute organ weight [g]				
- Prostate	0.757	0.741	0.745	0.676
% (compared to control)	100	98	98	89
- Seminal vesicle	0.939	0.907	0.887	0.872
% (compared to control)	100	97	94	93
- Testes	3.321	3.389	3.423	3.371
% (compared to control)	100	102	103	102

Table 5.8.3-19: Mean relative organ weights of rats administered alpha-cypermethrin

Sex	**Males**			
Test-item	Control	Alpha-cypermethrin		
Dose level [mg/kg bw]	0	2.0	3.5	6.6
Mean relative organ weight [g]				
- Prostate	0.243	0.241	0.242	0.221
% (compared to control)	100	99	100	91
- Seminal vesicle	0.302	0.296	0.288	0.285
% (compared to control)	100	98	95	94
- Testes	1.066	1.104	1.113	1.100
% (compared to control)	100	103	104	103

Comparison of weight parameters with historical control data

When compared to historical control data of three studies using animals with an age of 83 days at terminal kill, the following observations were made:

- The terminal body weight of both control and test group 3 (6.6 mg/kg bw/d) of this study were slightly lower than historical controls
- Absolute prostate weights were higher in the control of this study than in historical controls, while test group 3 weights were within historical controls.
- Relative prostate weights were within historical controls.
- Absolute and relative seminal vesicle weights were within historical controls.

Historical control data

	Study 1		Study 2		Study 3	
	absolute	relative	absolute	relative	absolute	relative
Number of animals	10	10	10	10	10	10
Terminal body weight	348.01 g		315.95 g		325.74 g	
Prostate	0.606 g	0.174	0.642 g	0.204	0.730	0.226
Seminal vesicles	0.842 g	0.241	0.989 g	0.313	0.906	0.281

Present study

Test group	0	3	0	3
	absolute	absolute	relative	relative
Number of animals	15	15	15	15
Terminal body weight	311 g	307 g		
Prostate	0.757 g	0.676 g	0.243	0.221
Seminal vesicles	0.939 g	0.872 g	0.302	0.285

No relevant weight changes were observed after comparison with historical controls.

2. Gross lesions

All findings occurred either individually or were biologically equally distributed over control and treatment groups. They were considered to be incidental or spontaneous in origin and without any relation to treatment. These findings included discoloration of lymph nodes, foci (liver, glandular stomach, epididymides) or pelvic dilation in the kidney.

3. Histopathology

All findings occurred either individually or were biologically equally distributed over control and treatment groups. They were considered to be incidental or spontaneous in origin and without any relation to treatment.

Specific attention was given to round spermatids and pachytene spermatocytes in stage VII and VIII tubules, as apoptosis in these cells would indicate testosterone depletion (Creasy, 2001). No indication of this finding was found.

4. Immunohistology

Mean values of positive Sertoli cells per tubule perimeter:

		Stage VII	Stage VIII	Stage IX
Test group 0 (0 mg/kg bw/d)	Mean	22.6	20.0	19.7
	SD	2.4	2.6	3.2
	N	15	15	15
Test group 3 (6.6 mg/kg bw/d)	Mean	22.2	21.3	20.7
	SD	2.5	2.9	3.3
	N	15	15	15

Wilcoxon (two-sided): *p ≤ 0.05, **p ≤ 0.01
N = Number of animals per test group
SD = Standard deviation

No significant differences in androgen receptor staining could be detected.

Regarding androgen receptor staining, no differences were observed comparing test groups 0 (control) and 3 (6.6 mg/kg bw/d).

The evaluation of androgen receptor staining was triggered by the following publications:

- Hu JX, Li YF, Li J, Pan C, He Z, Dong HY, Xu LC. (2013) Toxic effects of Cypermethrin on the male reproductive system: with emphasis on the androgen receptor. J Appl Toxicol. 33, 576–585
- Lu Liu, Jin-xia Hu, He Wang, Bao-jun Chen, Zhen He, Li-chun Xu (2010) Environmental Toxicology and Pharmacology 30, 251–256

In publication of Liu et al. (2010), the expression of the androgen receptor was measured using grey pixel scale values on whole slides without counting specific cells. This approach is not appropriate to discover stage-specific differences in androgen receptor staining, as the number of tubules in specific stages was not determined.

Therefore, the stage aware evaluation of Hu et al. (2013) was preferred with the following alterations of their protocol:

- Fixation of testis was in modified Davidson's solution, in contrast to Hu et al. (2013), who fixed their tissue in Bouin's. In the literature, Latendresse et al. (2002) reported that tubular shrinkage can occur with Bouin's fixative and that androgen receptor staining was weaker or absent in central tubules with Bouin's fixative as compared to modified Davidson's solution.
- Hu et al. (2013) evaluated 100 visual fields for each group and five fields per image. All positive cells were counted on those images. In Hu et al. (2013), it was not transparent how many tubules of each stage were evaluated, and how the different sizes of tubules due to the anatomical cut section in histology were taken into account. In this study, we selected approximately 100 tubuli of a given stage for each group. In addition, only the positive Sertoli cells of a given tubule were counted and set in relation to the perimeter of that tubule to normalize the number of positive cells to the size of the tubule. This approach is used in evaluation of cell proliferation of e.g. the nasal cavity where positive cells are given per unit length (Monticello et al., 1990).

- Hu et al. (2013) divided their stage evaluation into a combination of V/VI; VII/VIII, and IX. In this study stages VII, VIII, and IX were evaluated separately as differences in staining between stages VII and VIII could not be excluded at the beginning of the study.
- Slides were counterstained with hematoxylin, as staging is not possible without recognizable nuclear detail. No mention of a counterstained was made in Hu et al. (2013).

Taking into account all considerations mentioned above no differences in androgen receptor staining were observed comparing test group 0 and 3. Results by Hu et al. (2013) reported for cypermethrin could not be confirmed for alpha-cypermethrin.

5. Sperm parameters

Concerning the motility of the sperms and the incidence of abnormal sperms in the cauda epididymidis as well as the sperm head counts in the testis and in the cauda epididymidis no treatment-related effects were observed.

Table 5.8.3-20: Sperm parameters of rats administered alpha-cypermethrin

Sex	**Males**			
Test-item	Control	Alpha-cypermethrin		
Dose level [mg/kg bw]	0	2.0	3.5	6.6
Sperm motility (day 15)				
Mean	83	81	84	82
SD	8	10	6	9
TS/gT (day 15) [Mio/g]				
Mean	120	111	113	109
SD	27	26	32	30
TS/gC (day 15) [Mio/g]				
Mean	541	570	552	511
SD	145	166	131	164
Abnormal (day 15) [%; Cut off 6%]				
Mean	6.1	8.6	6.0	6.0
SD	0.4	9.9	0.0	0.0

TS: total sperm count; T: Testis; C: Cauda epididymis

6. Hormon levels

Since there was no indication for any hormonal change based on reproductive organ weights, sperm analysis and histopathology examinations, measurements of FSH, LH and testosterone in the serum samples were not performed and are not considered necessary to determine the absence of any adverse effects on hormone regulated organs and spermatogenesis.

III. CONCLUSIONS

After administration of alpha-cypermethrin at doses of 2.0, 3.5, and 6.6 mg/kg bw by gavage to adult intact male Wistar rats for 15 days in corn oil no findings with regard to clinical examination,

food consumption, body weight, and organ weights were observed when compared to the control animals. Sperm motility and morphology as well as sperm head counts in testes or in cauda epididymidis were not influenced by the test item. Histopathology and immunohistology androgen receptor staining revealed no substance-related effects.

In conclusion, under the conditions of this study a NOAEL of 6.6 mg/kg bw/day can be derived in adult intact male Wistar rats for effects on hormone regulated male reproductive organs and spermatogenesis.

CA 5.9 Medical Data

Information evaluated in the draft monograph of the Rapporteur Member State Belgium in Sep., 1999: Alpha-cypermethrin belongs to the group of pyrethroids, therefore the reported data were already at the stage of first annex I inclusion broad based on data with cypermethrin and pyrethroids in general. However it was concluded that despite the extensive world-wide use of alpha-cypermethrin, there were relatively few reports of effects seen in humans and the overall summary from the monograph 1999 was as follows:

"The salient clinical effect of alpha-cypermethrin exposure in humans is a transient-sensation experienced usually in the facial skin around the mouth and jaws or cheeks and the forehead following direct skin contact, often with insignificant amounts such that the individual is usually unaware of the exposure at the time. This paresthesia, as the abnormal sensation is called, is somewhat subjective as it is not associated with any visible or objective skin irritation such as erythema, eczematisation or local swelling. The symptom is variously described as being a sensation of coldness or numbness or, alternatively, burning, which can be quite painful, tingling or a sunburn-like smarting. The onset of paresthesia may not occur for several hours after exposure, and is not immediately relieved by washing, but usually wears off within a few hours to 24 hours."

Furthermore, European Chemicals Bureau decided in 2001 (ECBI/64/01, October 2001) to classify alpha-cypermethrin for respiratory irritation based on human observations with cypermethrin and based on animal data for alpha-cypermethrin.

The following conclusion was given in the Review Report (SANCO/4335/2000 final from 13.Feb. 2004) for list of endpoint listing of alpha-cypermethrin:

Medical data	Paresthesiae and peripheral sensory phenomena and irritation of respiratory tract; R37

Information on medical data obtained since then has been collected and evaluated. In order to extend the evaluation basis a search in the literature has been performed.

The relevant document s are summarized in the chapter CA 5.9

Considering all available information, the conclusion for relevant endpoints for the current renewal remains as follows:

Medical data (SANCO/11802 data point 5.9)

.....	Paresthesiae and peripheral sensory phenomena and irritation of respiratory tract; R37

CA 5.9.1 Medical surveillance on manufacturing plant personnel and monitoring studies

All persons handling crop protection products are surveyed by regular medical examinations.
There are no specific parameters available for effect monitoring of alpha-cypermethrin.
Thus, the medical monitoring program is designed as a general health check-up. At the two production sites the following parameters are investigated:

Bayer Vapi Private Limited:

a) Quarterly medical examination of company employees in Form No. 22 as per Insecticide rules 1971. Insecticide Act, 1968 (46 of 1968) Chapter VIIIRule No. 37 – by factory medical officer.

- List of questionaries (symptoms) for all systems including neuromuscular psychological symptoms
- Finger nose test to each employee working in plant to rule out any neurological symptoms

b) Annual medical checkup:

- a general physical examination including anamnesis, physical examination, blood analysis, urine analysis, stool routine examination, Audiometry/Lung Function test, Electrocardiogram, x-ray Chest (PA) view.

Tagros Chemials India Ltd:

The surveillance program includes a general physical examination, blood analysis (Hb, DC, TC, ESR), urine analysis, x-ray Chest (PA) with opinion, Electrocardiogram, lipid profile, borne density test, Vision/Audiometry/Lung Function test,.

Adverse health effects suspected to be related to alpha-cypermethrin exposure have not been observed and no monitoring studies are known to the applicant.

CA 5.9.2 Data collected on humans

The peer review literature search revealed the following new reports:

Report:	CA 5.9.2/1 Costa C. et al., 2013a Cytokine patterns in greenhouse workers occupationally exposed to alpha-Cypermethrin: An observational study 2013/1417820
Guidelines:	none
GLP:	no (certified by none)

Executive Summary of Literature:

An investigation on greenhouse workers occupationally exposed to alpha-cypermethrin showed neither clinical signs of immunosuppression nor alterations in total leukocytes or leukocyte subpopulations This is consistent with findings in experimental studies in rats (see Immunotoxicity study CA 5.8.2/1).

Classification of study: Supplementary information

Report: CA 5.9.2/2
Elfman L. et al., 2005a
Acute health effects on planters of conifer seedlings treated with insecticides
2005/1043540
Guidelines: none
GLP: no
(certified by none)

Executive Summary of Literature:

In male tobacco farmers a lower sensory nerve conduction velocity in the sural nerves was observed as compared to controls. However, this study has several limitations such as office workers as control group, lack of controlling for confounders, coexposure to other pesticides.

Classification of study: Supplementary information

CA 5.9.3 Direct observations

Some cases of slight irritation of the skin and mouth and/or intoxication (headache, nausea, vomiting, ague, fatigue, aching muscles, drowsiness, dizziness, breathing difficulties) have been reported to BASF SE in Ludwigshafen in persons exposed to alpha-cypermethrin containing products in combination with other active ingredients and/or products.

From the open literature, the following clinical cases and poisoning incidents were available:

Report: CA 5.9.3/1
Majumdar B.B. et al., 2012a
Toxic intracerebral demeyelination in a case of suicidal Cypermethrin poisoning
2012/1367262
Guidelines: none
GLP: no
(certified by none)

Executive summary of literature:

A 17-year-old boy was admitted in the General Medicine indoor with complains of vomiting and salivation due to suicidal intake of an unknown poison. Further interrogation revealed an ingestion of 50 ml of "Ostad", having a concentration of 10% of cypermethrin in an emulsifiable concentrate, which is equivalent to 5 g of poison about 8 hrs ago. The calculated exposure assuming a body weight of 70 kg is around 70 mg/kg bw Cypermethrin of unknown isomeric composition.
This case had predominant neurological manifestations; however, tremor and fasciculations were not documented. After gradually recovery on the 3rd day the patient showed neurological deterioration on the 4th day, showing fever, hemodynamic collapse, and intermittently seizures over the next few days. Routine hematological and biochemical investigations were within normal limits. His liver function and renal function tests, hemogram, serum electrolytes and glucose were normal. Over the next 4 days, the patient gradually improved and regained hemodynamic stability, but his neurological symptoms lacked an improvement. An MRI of brain revealed patchy areas of demyelination in subcortical part of the cerebrum.
To the best of knowledge, no reported case of demyelinating plaques has been reported till date following this poison. It also causes an increased salivation, upper gastrointestinal bleeding, and rarely renal failure which might be partly induced by the type of formulation. The patient survived with supportive and symptomatic management and was discharged on the phase of ongoing recovery.

Report: CA 5.9.3/2
Martinez-Navarrete J. et al., 2008a
Accidental poisoning with Chinese chalk
2013/1417282
Guidelines: none
GLP: no
(certified by none)

Executive summary of literature:

A 1.5-year old child accidentally ingested half of a “Chinese chalk”, which contains deltamethrin and cypermethrin. A day later, the infant showed vomiting, cough, fever, drowsiness, and irritability and, respiratory distress. Eight days after symptomatic treatment the infant was discharged from hospital and no further complications were observed.

Classification of study: Supplementary information

CA 5.9.4 Epidemiological studies

The open literature revealed the following epidemiological study:

Report: CA 5.9.4/1
Elfman L. et al., 2011a
Detection of pesticides used in rice cultivation in streams on the island of Leyte in the Philippines
2009/1131087
Guidelines: none
GLP: no
(certified by none)

Executive summary of literature:

Elfman et al. 2009 examined 19 planters handled untreated und with imidacloprid- and cypermethrin-treated conifer seedlings. No acute health effect could be found regarding to the pesticides.

Classification of study: Supplementary information

Furthermore several investigations are published that try to correlate urinary pyrethroid metabolite excretion with health issues. As surrogate parameter for pyrethroid exposure in general 3-phenoxybenzoicacid (PBA) is used whereas exposure to cypermethrins (zeta-, beta-, alpha-cypermethrin and cypermethrin itself), permethrins, cyfluthrin leads to cis- and trans-dichlorodimethylvinylcyclopropane carboxylic acid in urine. As these are common metabolites, a conclusion on or association to alpha-cypermethrin is not possible but however a summary of exemplary discussed data is given in Table 5.9.4-1.

In summary the following data are presented:
One study (Kimata et al., 2009) reports urinary 3-PBA levels in residents of rural and suburban areas compared to occupational exposure of sprayers and non-sprayers showing higher values in occupational exposed persons.
2 studies (Imai et al; 2014 & Perry et al., 2007) investigating urinary 3-PBA levels in healthy population showing no correlation to any semen parameter. However, semen quality is correlated to several life style factors.
5 studies (Toshima et al., 2012, Ji et al., 2011, Meeker et al., 2008 & 2009 and Han et al., 2008) investigating patients who had infertility consultation at gynecology clinics. These data indicate several correlations between 3-PBA and reduced semen quality or changed hormonal status. But there is no clear and convincing picture and these studies have several limitations such as no standardized sample treatment, lack of control groups, and lack of controlling for confounders. Some of the studies show correlations that lack any reliability. Some of the authors themselves note that associations described could be by chance due to the number of statistical comparisons and analyses that were carried out. Therefore the data are considered only as supplemental information and the following overall conclusion is drawn:

In conclusion, a clear absence of any correlation between urinary pyrethroid metabolites and semen parameters in two studies within the normal (healthy) population group was reported. In the clinical studies among patients with presumed infertility issue the 3-PBA level in urine was repeatedly reported to be correlated with effects on semen parameters, but the spectrum of reported effects was inconsistent. Considering comparable 3-PBA levels in the healthy and the clinical studies, the described correlations between 3-PBA levels in urine and the reported inconsistent changes are clearly not associated but by chance.

Report: CA 5.9.4/2
Kimata A. et al., 2009a
Comparison of urinary concentrations of 3-Phenoxybenzoic acid among general residents in rural and suburban areas and employees of pest control firms
2009/1131086
Guidelines: <none>
GLP: no
(certified by <none>)

Executive Summary of literature:

According to this study 3-PBA levels are lower and comparable for rural and suburban residents which are not occupationally exposed to Pyrethroids compared to higher values found for sprayers the morning after the most recent pesticide spraying, but also for non-sprayers, which are defined as employees who have worked for pest control firms but have not been engaged in active pyrethroid spraying. This study suffers the weakness that it is not age adjusted, however it is discussed that several publications found no correlation between age and urinary excretion of pyrethroid metabolites so that the observed difference in age distribution between the groups is considered to have little impact on the results. The geometric means for 3-PBA in urine for residents are at levels of 0.32 ± 1.1 µg/g creatinine for rural residents and 0.49± 1.2 µg/g creatinine for suburban residents, which is mentioned to be identical to those of US and German populations. The occupational exposure led to a two-order magnitude of increase in geometric means of 3-PBA concentrations between sprayers (23.8 ± 1.4 µg/g creatinine) compared to residents.

Classification of study: Supplementary information

Correlations between urinary pyrethroid metabolite concentration and sperm parameters were investigated several times, some in general population, some among patients who had infertility consultation at a gynecology clinic.
The following two publications were selected to present data for general population:

Report: CA 5.9.4/3
Imai K. et al., 2013a
Pyrethroid insecticide exposure and semen quality of young Japanese men
2014/1242698
Guidelines: none
GLP: no
(certified by none)

Executive Summary of literature:

Imai et al; 2014 (Doc ID2014/1242698) reports a study on 323 Japanese healthy students and showed that environmental exposure to pyrethroid insecticides, measured via the surrogate 3-PBA in urine, did not affect semen quality (sperm motility, sperm count nor volume). 3-PBA was found in 91 % of the urine probes (LOD: 0.08 ng/mL). Geometric mean of unadjusted 3-PBA concentrations in urine were at a 0.68 µg/L (Range: <0.08-13.2µg/L). Fluctuations of 3-PBA concentrations were conditioned by season (higher values in sommer and autumn), whereas sperm effects were described in dependency of age, abstinence, testes size, varicoceles, and frequency of cheese/soy/ non-oily white fish consumption.

Classification of study: Supplementary information

Report: CA 5.9.4/4
Perry M.J. et al., 2006a
Environmental Pyrethroid and organophosphorus insecticide exposures and sperm concentration
2007/1070389
Guidelines: none
GLP: no
(certified by none)

Executive Summary of literature:

Perry et al., 2007 (Doc ID 2007/1070389) screened 18 randomly selected urine samples collected from male participants from China, Anhui in the Winter of 2004, all of reproductive age, for 24 parent compounds and metabolites of pesticides and examined the results in relation to sperm concentration. Results showed high prevalence of exposure to OP and PYR pesticides. 3-PBA was found in 100 % of the urine probes with a median at 1.1 µg/L and maximum values more than 20 times higher. Cis-dichlorodimethylvinylcyclopropane carboxylic acid (CDCCA, cis- DCVA) was found only in samples of the maximum exposure group (at a concentration of 12.1 µg/L). Trans-dichlorodimethylvinylcyclopropane carboxylic acid (TDCCA, trans - DCVA) was found in the median and the maximum exposure group. Although the investigation provide some suggestion that the higher exposure group had lower sperm concentrations, however, no correlation to PBA, cis-DCVA or trans-DCVA was found. A statistically significant difference in sperm concentration was found in correlation with the organophosphate representative diethylthiophosphate (DETP) in urine.

Classification of study: Supplementary information

In summary, among healthy representatives of the population no correlation was found between sperm parameters (sperm motility, sperm count and volume) and PBA, cis-DCVA or trans-DCVA.

Based on the inconsistency of the data presented in the following reports the data were not considered to be convincing. Therefore the reports were not further considered but are here only presented to demonstrate the inconsistency.

Report: CA 5.9.4/5
Toshima H. et al., 2011a
Endocrine disrupting chemicals in urine of Japanese male partners of subfertile couples: A pilot study on exposure and semen quality
2012/1367223
Guidelines: none
GLP: no
(certified by none)

Executive Summary of literature:

Toshima et al., 2012 (Doc ID 2012/1367223) measured urine samples from 42 Japanese male partners from infertility clinic (11 current smokers, only 1 of them was excluded) and found PBA levels in urine at 0.547 ± 2.76 µg/L (geometric mean) with a range of 0.160 - 7.72 µg/L (Corrected for specific gravity, LOD: 0.04µg/L). When the subjects were divided into two groups based on the semen parameter reference values (40% for motility and 15x106 for sperms / ml), Pearson correlation analysis found no correlation of motility or of sperm counts to PBA-concentration. However, in the multiple regressions analysis lower semen motility was associated with urinary 3-PBA concentration. However, the significance of this finding is already limited by the authors which state that some of the associations described could be by chance due to the number of statistical comparisons and analyses that were carried out. One point that strongly reduces the reliability of the study is the significant correlation of smoking and improved semen quality.

Classification of study: Not further considered

Report: CA 5.9.4/6
Ji G. et al., 2010a
Effects of non-occupational environmental exposure to pyrethroids on semen quality and sperm DNA integrity in Chinese men
2011/1296811
Guidelines: none
GLP: no
(certified by none)

Executive Summary of Literature:

240 men were recruited from an infertility clinic through the clinic following strict eligibility screening. Urinary 3-phenoxybenzoic acid (3-PBA) concentration, semen quality (sperm concentration, motility, total sperm count), and sperm DNA integrity were evaluated. After adjustment for potential confounders, a significant inverse correlation was observed between the urinary 3-PBA level and the sperm concentration. Moreover, we also found a significant positive correlation between urinary 3-PBA level and sperm DNA fragmentation (ˇ = 0.27, 95%CI: 0.15–0.39, P < 0.001). Our results suggest that non-occupational environmental pyrethroids exposure may have a negative impact on sperm DNA integrity and semen quality in Chinese males.

Classification of study: Not further considered

Report: CA 5.9.4/7
Meeker J.D. et al., 2008a
Human semen quality and sperm DNA damage in relation to urinary metabolites of Pyrethroid insecticides
2008/1102220
Guidelines: none
GLP: no
(certified by none)

Executive Summary of Literature:

Meeker et al (2008, Doc ID 2008/1102220) investigated the association between urinary pyrethroids metabolites, semen quality, sperm motion parameters and sperm DNA damage (neutral comet assay) in 207 men recruited from an infertility clinic at an age of 18 to 54 years. The metabolites that were determined included 3-phenoxybenzoic acid (3-PBA) and cis- and trans-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid (CDCCA and TDCCA) and others. There was a quite high proportion of samples below the limit of detection (LOD=0.1µg/L) for 3PBA (46%), CDCCA (47%) and TDCCA (49%). Multiple liniear regression as well as multiple logistic regression was performed. Preliminary bivariate analyses demonstrate that a higher metabolite concentration in the urine was associated with greater age whereas semen parameters were positively associated with abstinence period of sexual activity. The regression in semen quality with urinary metabolite groups were therefore adjusted for age and abstinence period. Meeker found that 3-PBA and TDCCA were associated with a reduction in sperm concentration, sperm motility and sperm motion parameters. Conversely, CDCCA and 3PBA were associated with increased sperm DNA damage, measured as percent DNA in the comet tail but not associated with comet extent or tail distribution moment.
However, the significance of this single finding is not convincing, especially due to the divers parameters that are known risk factors for infertility and which were not addressed in the investigation.

Classification of study: Not further considered

Report: CA 5.9.4/8
Meeker J.D. et al., 2008b
Pyrethroid insecticide metabolites are associated with serum hormone levels in adult men
2009/1131084
Guidelines: none
GLP: no
(certified by none)

Executive Summary of Literature:

In a second part Meeker et al., 2009 (Doc ID 2009/1131084) investigated several serum hormone levels within a subset of the former group. The regressions were adjusted for age and body mass index, smoking status, season and time of day but further risk factors were not integrated. The data show no clear picture and some very curious correlations were reported, like current smoking habit is negatively correlated with high cis-DCCA levels. The sum parameter (3-PBA, cis- and trans-DCCA) and 3-PBA alone were reported to be correlated with increased FSH levels.
Any conclusion on causality between urinary pyrethroid metabolite levels and serum hormone levels is not considered reliable based on these data.

Classification of study: Not further considered

This is substantiated by the following investigation which revealed a complete different picture

Report: CA 5.9.4/9
Han Y. et al., 2008a
The relationship of 3-PBA pyrethroids metabolite and male reproductive hormones among non-occupational exposure males
2008/1102218
Guidelines: none
GLP: no
(certified by none)

Executive Summary of Literature:

The authors investigated the association between serum reproductive hormone levels and urinary creatine adjusted concentration of 3-PBA level in Chinese adult men. The study subjects (n = 212) were from the affiliated hospitals of Nanjing Medical University. By using GC–MS, urinary 3-PBA level of each subject was measured and adjusted by urinary creatin. Blood samples were collected for measuring the serum levels of reproductive hormones, including follicle stimulating hormone (FSH), luteinizing hormone (LH), estradiol (E2), testosterone (T) and prolactin (PRL). All the subjects had detectable levels of 3-PBA in their urine samples. The median concentration of 3-PBA was 0.815 µg/g creatin. The results showed that there were positive associations between the levels of serum LH and 3-PBA (p = 0.013) but negative associations between E2 and 3-PBA level (p = 0.022), and the adjusting p-value was 0.044 for LH and E2, which suggested that pyrethroids are capable of disrupting the male endocrine function. A correlation to FSH was not found. The provided scatter plots for individual PBA levels and hormone levels rather show demonstrate a crude distribution of unrelated parameters.

Classification of study: Not further considered

Table 5.9.4-1: Overview of available studies investigating pyrethroid metabolite concentration in urine and possible correlation to health parameters in humans.

Author	Subject	Investigations/questionnaire	Samples	3-PBA concentration (in urine)*	Dependency	Strength	Weakness
Exemplary 3-PBA levels in residents and occupational exposed persons							
Kimata et a., 2009, Doc ID 2009/1131086	143 male from rural area, 66 males from suburban area, pest control workers (sprayers, n= 14; non-sprayers, n= 16) (2005-2007)	Age (years), Current smoking and drinking habits (yes/no) Weight and height were measured	- Urine (3-PBA analysis, creatinine content (CR))	Adjusted (CR): Rural residents: 0.32 ± 1.1 µg/g CR Suburban residents: 0.49± 1.2 µg/g CR Sprayers: 23.8 ± 1.4 µg/g CR Non Sprayers: 5.4 ± 1.3 µg/g CR (LOD=0.02µg/l)	No difference of 3-PBA levels in rural or suburban populations Increased 3-PBA levels in sprayers and also in non-sprayers	Population based	No adjustment for age or seasonal changes
3-PBA levels and sperm parameters in healthy population							
Imai et al., 2014 DocID 2014/1242698	Male student (n=322), 18-24 years, mother/himself born in Japan, healthy (1999-2000, 2002-2003	- Abstinence period - Testis size - Varicoceles - Lifestyle information (smoking, alcohol consumption, frequency of selected food stuff consumption) - Physical examination	- Semen (sperm motility, sperm count, volume) - Urine (3-PBA analysis, specific gravity)	Unadjusted: 0.68 ± 3.26 ng/mL Adjusted (SG): 0.59 ± 3.12 ng/mL	sperm correlates to: 3-PBA: no influence Age, abstinence, testes size, varicoceles: yes Vegetables/fruit consumption: No Cheese/soy/ non-oily white fish: Yes 3-PBA correlates to Season: yes Food composition (beef/vegetables): no	Population based	Students of a limited geographical region

Author	Subject	Investigations/questionnaire	Samples	3-PBA concentration (in urine)*	Dependency	Strength	Weakness
Perry et al., 2007 Doc ID 2007/1070389	Males young (n=202; samples n=18), no pesticide users (but with home villages consisting of agricultural background) (2004)		- Semen (sperm concentration) - Urine (3-PBA, cis/trans-DCCA),	Unadjusted (median; ng/mL): - 3-PBA: 1.1 ng/mL - cis-DCCA: <LOD - trans-DCCA: 0.1 ng/mL	No effects of pyrethroids metabolites but effect of DETP on sperm concentration	Population based, 24 pesticides determined in total	
3-PBA levels and sperm parameters in hospital based popultion							
Toshima et al., 2012 Doc ID 2012/1367223	41 men from infertility clinic, 29-58 years (2010)	- lifestyle information (smoking, dietary habit)	- Semen (sperm motility, sperm count, volume), - Urine (3-PBA, specific gravity), Other metabolites	Adjusted (SG): 0.547±2.76 ng/mL	sperm parameters correlate with: -3-PBA reduce motility; -Isoflavones reduce motility/concentration -Age, Alkohol, Coffee: no effect -Smoking: increased semen quality	Further chemicals investigate (phthalates, isoflavones)	Hospital based, semen sampling at home
Ji et al., 2011 DocID 2011/1296811	Males from infertility clinic (n=240), 28.5±3.6 years, mother/himself born in Japan, healthy, lifestyle information asked (2005-2007)	- abstinence period - physical examination - lifestyle information asked	- Semen (sperm motility, sperm count, volume), - Urine (3-PBA analysis), - DNA fragmentation	0.19-10.37 µg/g of CR Median: 1.12 ng/mL	3-PBA correlates with - Sperm conc.: Yes - Total sperm count: Yes - DNA fragmentation: Yes - Seminal volume: No - Motility: No		Hospital based
Meeker et al., 2008 DocID 2008/1102220	Males from infertility clinic (n=207), 18-54 years (2000-2003)	- Exclusion criteria: varicoceles, orchidopexy, use of exogenous hormones- self-reported - health information asked	- Semen (sperm motility, sperm count, volume, morphology), -urine (3-PBA, cis/trans-DCCA, specific gravity) - DNA fragmentation	Adjusted (SG); 90th percentile; ng/mL): - 3-PBA: 1.31 - cis-DCCA: 0.58 - trans-DCCA: 1.25	3-PBA correlates with: - Sperm conc.: yes - Total sperm count: Yes - DNA fragmentation: Yes - Motility: Yes (Effect when compared >75% percentile with below median; no trend was observed within percentiles)	Higher number of samples	Hospital based

Author	Subject	Investigations/questionnaire	Samples	3-PBA concentration (in urine)*	Dependency	Strength	Weakness

Han et al., 2008; Doc ID2008/1102218	Chinese adult men (n=212), 20- 40 years, (2004-2006)	- Detailed physical examination(height, weight) - Questionnaire (lifestyle factors (smoking, drinking, psychologic tension, sleep quality), occupational and environmental exposures, genetic risk factors, sexual and procreate state, medical history, physical activity) - Exclusion criteria: hormonal medications, genetic disease, occupational exposure to pesticides;	Urine (3-PBA, creatinine) - Serum (testosterone, LH, FSH, E2, prolactin)	(n=199) Adjusted (CR): - 3-PBA: 0.925 µg/g Unadjusted: - 3-PBA: 1.398 µg/L	3-PBA correlates with: - ↑ LH and E2		Hospital based

* 3-PBA concentration in urine is given as geometric mean if not mentioned otherwise, correction was done for specific gravity (SG) or creatinine content (CR)

CA 5.9.5 Diagnosis of poisoning (determination of active substance, metabolites), specific signs of poisoning, clinical tests

Expected clinical signs and symptoms of poisoning based on animal studies:
In acute toxicity studies in animals transient signs of neurotoxicty were seen after exposure to moderate doses of alpha-cypermethrin, whereas higher doses higher doses could be lethal. In repeated dose toxicity studies skin irritation effects were repeatedly seen.
Based on the rapid absorption with peak plasma levels reached within 6-9 hours and the nearly complete elimination within 48 hours and assuming a similar absorption kinetic for humans, onset of clinical signs after (sufficiently high oral exposure) may be expected within several hours and potential symptoms of acute poisoning are expected to decrease in parallel to elimination. In acute toxicity studies first symptoms were already seen after 1 hour.

In humans the occurrence of "facial sensations" (Paresthesiae) is an indication of exposure.

Several biomarkers .(e.g. 3-PBA) can be detected in human urine by chromatography.

The passage from the original DAR from 1999 is still valid:
“The facial paresthesiae described following direct contact of the facial skin with alphacypermethrin are highly characteristic, especially in the absence of any visible sign of skin irritation such as erythema, swelling, blistering, exudation or desquamation, etc. The urinary metabolite of alphacypermethrin (the methyl ester of the cis-isomer of 3-(2,2-dichlorovinyl)-2,2-dimethyl-cyclopropane carboxylic acid) can be identified and measured with a limit of detection of 0.003 mg/liter. It would not appear useful, therefore, to perform a urinalysis in most cases of facial paresthesiae, since it is most unlikely that the urinary metabolite would reach the level of detection in the urine following skin contact exposure, sufficient to cause the transient paresthesiae. (Van Sittert, 1982)

The signs of systemic poisoning by alpha-cypermethrin following accidental ingestion, appear to be non-specific. Acute intoxications by synthetic pyrethroids in general have been reported to lead to signs and symptoms such as dizziness, headache, nausea, anorexia, fatigue, gastrointestinal complaints and fever. In severe cases, exposure has resulted in impaired consciousness, muscular fasciculations, convulsions, coma and pulmonary edema. The signs and symptoms of acute intoxication appear to be very similar for all types of pyrethroids, presumably including alpha-cypermethrin.”

From the above, it would appear to be very difficult to differentiate pyrethroid poisoning from either organophosphate or carbamate poisoning. Systemic poisoning by these anticholinergic agents from occupational exposure is much more commonplace, and because specific and effective treatment for the latter is available, a blood cholinesterase test might prove useful to exclude organophosphate or carbamate poisoning.

CA 5.9.6 Proposed treatment: first aid measures, antidotes, medical treatment

In case of skin contact paraesthesia usually resolve in 12 – 24 hours. Specific treatment is not generally required. However, topical application of dl-alpha tocopherol acetate (vitamin E) reduced the serverity of skin reactions to cypermethrin.

In case of ingestion the stomach should be washed out by intubation as soon as possible, since induction of vomiting is not recommended.

For acute systemic intoxication there is no specific antidote. Convulsions should be treated with anti-convulsants such as diazepam. Isolated brief convulsions do not require treatment but intravenous diazepam (5-10mg) should be given if seizures are prolonged. Diazepam is also useful in the treatment of muscle fasciculation. Treatment should otherwise be symptomatic or supportive.
The use of methocarbamol, a skeletal muscle relaxant, to reduce mortality, as reported in the DAR 1999, could not be confirmed in a further antidot study (see CA 5.8.2/3). Also the use of mephenesin did not show any protective effects on the incidence or latency of the toxicity. Halothane protected the animals from the acute toxic signs (salivation and convulsions) although it had no protective effects on the lethality.

The use of atropine, which may be life-saving in the case of organophosphate or carbamate poisoning, needs careful control in case of pyrethroid poisoning as it is contraindicated at high doses. A blood cholinesterase test may, therefore, be of crucial importance in making this discrimination. Intravenous atropine (0.6 – 12 mg in an adult) may be useful in controlling excess salvation, but care should be taken to avoid excess administration. It is unlikely to have an effect on pulmonary edema. (Bradberry et al; (2005); Doc ID 2005/1043400).

In a general pharmacological study (CA 5.8.2/2) effects of alpha-cypermethrin on the autonomic and central nervous system, effects on respiration and circulation, effects on digestive organs, effects on skeletal muscles and renal function were investigated. The test substance produced acute toxicities through its action of nervous and cardiorespiratory systems at sublethal doses close to lethal doses.

CA 5.9.7 Expected effects of poisoning

Acute but normally transient signs of neurotoxicity were seen in animals after exposure to sub-lethal doses of alpha-cypermethrin. Reports on human poisonings indicate similar effects.

After local contact paresthesiae is a well-known symptom.
Typically there may be a delay of one to several hours between facial skin contamination by alpha-cyano-pyrethroids, including alpha-cypermethrin, and the onset of the characteristic paresthesiae. The sensations may then last for several hours up to one day or more before disappearing. It is not clear whether that variation in duration of the symptoms is strictly dependent on the degree of contamination, i.e., the dose delivered to the skin, upon individual variation, or a combination of the aforementioned factors.

1 Introduction

Alpha-cypermethrin (BAS 310 I) belongs to the class of synthetic pyrethroid insecticides. It is a non-systemic insecticide and is registered against insect pests in various crops belonging to the crop groups of cereals, oilseeds, fruits and vegetables. As a consequence of its use, residues might result in plant items destined for human food or animal feed.

This document summarizes supplemental information on the residue situation in crops not belonging to the representative uses for the Annex I renewal. It gives information on residue field and glasshouse studies, processing data and the relevant residue values (MRLs, HRs and STMRs) derived and used for risk assessment purposes in the main dossier. For each crop, a chapter is included summarizing the supervised field trials, processing studies (if applicable) and an assessment of the residue data to derive an MRL, STMR and HR. For the MRL calculations, the current version of the OECD calculator was used. All individual residue data used for the consumer dietary risk assessment of alpha-cypermethrin (BAS 310 I) are summarized in table format in the appendix to this supplement, including document and trial number, PHI, residue value, and the calculated HRs and STMRs (Table 5-1 and Table 5-2).

In the residue trials summarised below, several formulated products were used: BAS 310 03 I (SC), BAS 310 QC I (SC), BAS 310 11 I (EC), BAS 310 40 I (EC), BAS 310 08 I (WG), BAS 310 41 I (SC), Fastac SC (SC), BAS 310 51 I (ME), BAS 310 55 I (ME), alpha-cypermethrin 50 g as./L EC, alpha-cypermethrin 50 g a.s./kg PVP, alpha-cypermethrin 100 g as./L OSK and BAS 310 63 I (CB). Most of the trials were carried out with the formulation BAS 310 40 I. Bridging trials with the formulations BAS 310 40 I and BAS 310 08 I on tomato (see 2.8.1), cauliflower (see 2.12.1) and lettuce (see 2.16.1) show similar residues for both products. The study summaries on grape, olive, tomato and lettuce also include bridging trials, demonstrating that alpha-cypermethrin residues after application of BAS 310 40 I are comparable to residues found after use of BAS 310 51 I or BAS 310 55 I, respectively. According to European Community Guideline 7527/VI/95 of March 2011, EC, WP, WG and SC formulations usually produce comparable residues. Since the formulation BAS 310 55 I is a micro-emulsion (ME) with only minor changes to BAS 310 51 I, and residues after application of all above-mentioned products are demonstrated to be similar, those formulations are considered suitable to describe the residue behaviour of alpha-cypermethrin.

2 Food of plant origin

2.1 Grape

Residue data from supervised trials in grapes were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Material and Methods:

In the years 2003, 2004, 2005 and 2006 a field program on grapes was conducted in representative wine growing areas in France (Northern and Southern European region), Germany, Greece, Italy, and Spain to investigate the residue behaviour of alpha-cypermethrin.

During the 2003 growing season, four field trials were conducted in grapes in the Northern part of France. An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L; BAS 310 11 I) was foliar applied on grapes on two different plots in each trial. In one variant, one treatment was done at a target rate of 15 g a.s./ha. This was compared to two treatments with the same application rate. The last application took place at growth stages between 85 (softening of berries) and 89 (berries ripe for harvest). Grape specimens were collected directly after the last application as well as 3-4, 7 and 14 days thereafter.
The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS with BASF method No. 546/0 which has a limit of quantification of 0.05 mg/kg in all sample materials.

In the same year, four field trials were conducted with wine grapes in Spain and Italy. An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L; BAS 310 11 I) was foliar applied to grapes twice at a target rate of 15 g a.s./ha. The last application took place at growth stage 85. Grape specimens were collected directly after the last application as well as 3, 6-7 and 14 days thereafter. The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS with BASF method No. 546/0 which has a limit of quantification of 0.05 mg/kg in all sample materials.

During the 2004 growing season, a total of four field trials were conducted on grapes in Germany and in the Northern part of France. Each trial included separate plots which were treated with alpha-cypermethrin formulated as a soluble concentrate (100 g a.s./L; BAS 310 41 I) either once at a target rate of 15 g a.s./ha, or twice at a target rate of 15 g a.s./ha. The last application took place at growth stages between 85 and 89. Bunches were collected just after the last application, then 3, 7 and 14 days after the last application. The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS using BASF method No. 567/0 which has a limit of quantification of 0.01 mg/kg in all sample materials.

During the 2004 growing season, a total of four field trials were conducted in Southern France and Greece. A soluble concentrate formulation of alpha-cypermethrin (100 g a.s./L; BAS 310 41 I) was foliar applied to grapes twice at a target rate of 15 g a.s./ha. The last application took place at growth stages between 79 (majority of berries touching) and 85 (softening of berries). Grape fruit specimens were sampled directly after the last application as well as 2-3, 6-7 and 13-14 days thereafter. The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS using BASF method No. 567/0 which has a limit of quantification of 0.01 mg/kg in all sample materials.

During the 2005 growing season, eight field trials were conducted in representative vineyards in France (Northern and Southern European region), Italy, Spain, Greece and Germany.
An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L; BAS 310 40 I), was foliar applied to separate plots of grapes either once or twice at a target rate of 12.5 g a.s./ha. The last application took place at growth stages between 83 (berries developing colour) and 89 (berries ripe for harvest). Specimens of grape bunches were collected immediately after the last application from each plot as well as 2-4, 7-8, and 14 days thereafter.
The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS using BASF method No. 567/0 which has a limit of quantification of 0.01 mg/kg in all sample materials.

During the 2006 growing season, eight field trials were conducted in representative vineyards in France (Northern and Southern European region), Germany, Greece, Italy, and Spain.
An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L; BAS 310 40 I), was foliar applied to separate plots of grapes either once or twice at a target rate of 12.5 g a.s./ha.
The last application took place at growth stages between 79 (majority of berries touching) and 88. Specimens of grape bunches were collected immediately after the last application (0 DALA) from each plot as well as 3-4, 6-8, and 13-15 days thereafter.
The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS using BASF method No. 567/0 which has a limit of quantification of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarized in Table 2.1.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in grapes presented in the alpha-cypermethrin dossier were carried out in 5 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 14 days
- for the Southern European region: 2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha – 16 trials including both variants, 8 conducted in the Northern European Region and 8 conducted in the Southern European Region
- one or two treatments at a target rate of 15 g a.s./ha - 8 trials including both variants, all conducted in the Northern European Region
- two treatments at a target rate of 15 g a.s./ha - 8 trials, all conducted in the Southern European Region.

After one application at 12.5 g a.s./ha, initial residues ranged between <0.01 mg/kg and 0.049 mg/kg and declined to <0.01 – 0.044 mg/kg, <0.01 – 0.043 mg/kg and <0.01 – 0.033 mg/kg at 2-4, 6-8 and 13-15 days after application, respectively.

After two applications at 12.5 g a.s./ha, initial residues ranged between 0.013 mg/kg and 0.082 mg/kg and declined to <0.01 – 0.077 mg/kg, <0.01 – 0.064 mg/kg and <0.01 – 0.063 mg/kg at 2-4, 6-8 and 13-15 days after application, respectively.

A total of 16 residue trials was performed to investigate the residue behaviour after application of either one or two treatments at a rate of 15 g a.s./ha. These trials were conducted during the growing seasons 2003 and 2004. Residue analysis of the samples generated in these studies was carried out according to two different methods with different limits of quantification (LOQ): while the samples from the 2003 studies were analysed according to method No 546/0 with a LOQ of 0.05 mg/kg, the samples from the 2004 trials were analysed with method N° 567/0 which has a lower validated LOQ of 0.01 mg/kg.

In the year 2003, 4 trials were conducted in the Northern European Region with either one or two treatments at a rate of 15 g a.s./ha applied to separate plots. In Southern Europe, 4 trials were conducted with two applications at a rate of 15 g a.s./ha. The samples generated in these studies were analysed according to BASF method No. 546/0 with a LOQ of 0.05 mg/kg. No residues above the LOQ were found in any of the treated samples from all of these trials, regardless of number of application or sampling interval (all <0.05).

In the year 2004, 4 trials were conducted in the Northern European Region with either one or two treatments at a rate of 15 g a.s./ha applied to separate plots. In Southern Europe, 4 trials were conducted with two applications at a rate of 15 g a.s./ha. The samples generated in these studies were analysed according to BASF method No. 567/0 with a LOQ of 0.01 mg/kg.
After one application at 15 g a.s./ha, initial residues in fruit ranged between <0.01 and 0.021 mg/kg. Residues between <0.01 – 0.046 mg/kg, <0.01 – 0.011 mg/kg and <0.01 – 0.014 mg/kg were found 3, 7 and 14 days afterwards.

After two applications at 15 g a.s./ha, initial residues between 0.014 and 0.090 mg/kg were found in fruit or bunches, respectively. Residues between 0.010 – 0.084 mg/kg, 0.018 – 0.055 mg/kg and 0.013 – 0.069 mg/kg were found 2-3, 6-7 and 13-14 days afterwards.

Conclusion:

The residue studies presented demonstrate that residues in grapes treated with alpha-cypermethrin according to the proposed GAP are below a level of 0.1 mg/kg at the target PHI.

Executive Summary

During the growing season of 2011, a total of four trials with grapes were conducted in Germany, Northern France, Spain and Greece to determine the magnitude of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC). Therefore two solo formulations BAS 310 55 I (50 g/L BAS 310 I, ME) and BAS 310 40 I (100 g/L BAS 310 I, EC) were applied once to the treated plot at a rate equivalent of 0.0125 kg a.s./ha. In all trials the applications were made at crop stages between BBCH 87 and 89.

For the analysis the grape specimens were taken immediately after the last treatment (0 DALA) and at 2-3, 6-8 and 13-15 DALA. The grape specimens were analysed for residues of BAS 310 I according to BASF Method No. 567/0, which has a limit of quantitation (LOQ) of 0.01 mg/kg. Directly after application of BAS 310 55 I and BAS 310 40 I, the residue of alpha-cypermethrin ranged between 0.01-0.06 mg/kg in grape specimens. At 6-8 DALA, residues found were 0.02-0.05 mg/kg, and at 13-15 DALA residues ranged between <0.01-0.04 mg/kg.

The analytical results obtained demonstrate that the treatment with one application of BAS 310 55 I and BAS 310 40 I did not lead to significantly different residue results in the raw agricultural commodity at harvest.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 55 I (ME)
BAS 310 40 I (EC)
Lot/Batch #: 101198 BAS 310 55 I, 50 g/L alpha-cypermethrin
1209 BAS 310 40 I, 100 g/L alpha-cypermethrin
Purity:
CAS#: 67375-30-8 alpha-cypermethrin
Development code:
Spiking levels: 0.01-5.0 mg/kg

2. Test Commodity:

Crop: Grape
Type: Berries and other small fruit
Variety: Vanessa, Topkapi, Asterix, Brillante
Botanical name: *Vitis vinifera*
Crop parts(s) or processed
Commodity: Fruit
Sample size: 1.0 kg (12 bunches)

B. STUDY DESIGN

1. Test procedure

During the growing season of 2011, a total of four trials with grapes were conducted in Germany, Northern France, Spain and Greece to determine the magnitude of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC). Therefore two solo formulations BAS 310 55 I (50 g/L BAS 310 I, ME) and BAS 310 40 I (100 g/L BAS 310 I, EC) were applied once to the treated plot at a rate equivalent of 0.0125 kg a.s./ha.
BAS 310 55 I was spray-applied at a rate of 0.250 L/ha of formulated product, corresponding to 0.0125 kg/ha of BAS 310 I.
BAS 310 40 I was spray-applied at a rate of 0.125 L/ha of formulated product, corresponding to 0.0125 kg/ha of BAS 310 I.
The water volume was 800 L/ha. The applications took place 6 – 8 days before harvest (DBH), at crop stages between BBCH 87 and 89. At the sampling occasion 0 DALA, the untreated specimens were collected immediately before the last application of the treated plots. The treated wine grape specimens were sampled immediately after the application (0 DALA), as well as 2 – 3 DALA, 6 – 8 DALA (PHI) and 13 – 15 DALA.
In all trials the applications were made at crop stages between BBCH 87 and 89.
For the analysis the grape specimens were taken immediately after the last treatment (0 DALA) and at 2-3, 6-8 and 13-15 DALA.

Table 2.1.1-2: Target application rates and timings for grape

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2011	4	1	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.0125	800	1st appl.: 7 ± 1 DBH
		1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	800	1st appl.: 7 ± 1 DBH

DBH: days before harvest

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin).
The residues of alpha-cypermethrin in grape specimens were extracted with methanol/water/hydrochloric acid (70:25:5, v/v/v). After centrifugation, an aliquot of the extract was partitioned into cyclohexane. An aliquot of the cyclohexane phase was evaporated and the residue was taken up into methanol/water (80:20, v/v). Final determination was performed by LC/MS/MS using the ammonium adduct of cypermethrin.
The limit of quantitation (LOQ) of the method is 0.01 mg/kg. The mean procedural recovery in wine-grapes averaged 86±7% (mean ± RSD) for alpha-cypermethrin at fortification levels of 0.01 and 5.0 mg/kg.

Table 2.1.1-3: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in grapes

Matrix	Fortification Level (mg/kg)	Summary Recoveries		
		n	Mean (%)	RSD (%)
Method No. 567/0		alpha-cypermethrin		
Wine-grapes	0.01	4	84	3
	5.0	4	88	8

II. RESULTS AND DISCUSSION

The residue levels of alpha-cypermethrin (BAS 310 I) in grape specimens taken directly after the last application (0 DALA) of BAS 310 55 I ranged between 0.01-0.06 mg/kg in all trials. In the specimens taken 2-3 DALA 0.02- 0.05 mg/kg were found. The residues remained at this level at 6-8 DALA (0.02- 0.04 mg/kg). At the last sampling (13-15 DALA) < 0.01-0.04 mg/kg were found.

Residues found in grape specimens taken directly after the last application (0 DALA) of BAS 310 40 I contained residues of BAS 310 I in a range of 0.03 mg/kg to 0.06 mg/kg. They decreased slightly to 0.02- 0.03 mg/kg in the specimen taken 2- 3 DALA. At 6-8 DALA 0.02-0.05 mg/kg were found. At the last sampling (13- 15 DALA) the residues remained at this level (0.01- 0.04 mg/kg).

No residues of BAS 310 I (alpha-cypermethrin) above the limit of quantification were found in any of the analysed untreated specimens.
An overall summary of the residues is given in the table below.

Table 2.1.1-4: Summary of residues of BAS 310 I in grape after application of BAS 310 55 I and BAS 310 40 I

Crop	Year	No. of Appl.	Application	DALA	BBCH	Residues Found (mg/kg)	
						Matrix	alpha-cypermethrin (BAS 310 I)
Wine-grapes	2011	1	BAS 310 55 I (ME)	0	87-89	fruit	0.01 – 0.06
				2-3	87-89		0.02 – 0.05
				6-8	87-89		0.02 – 0.04
				13-15	89		< 0.01 – 0.04
		1	BAS 310 40 I (EC)	0	87-89	fruit	0.03 – 0.06
				2-3	87-89		0.02 – 0.03
				7-8	87-89		0.02 – 0.05
				13-15	89		0.01 – 0.04

DALA = days after last application
BBCH = growth stage at respective sampling

III. CONCLUSION

Directly after application of BAS 310 55 I and BAS 310 40 I, the residue of alpha-cypermethrin ranged between 0.01-0.06 mg/kg in grape specimens. At 6-8 DALA, residues found were 0.02-0.05 mg/kg, and at 13-15 DALA residues ranged between <0.01-0.04 mg/kg. The analytical results obtained demonstrate that the treatment with one application of BAS 310 55 I and BAS 310 40 I did not lead to significantly different residue results in the raw agricultural commodity at harvest.

2.1.2 Processing study in grape

Report:	Raunft E, Hafemann C, Mackenroth C. 2005a Study on the residue behaviour of alpha-cypermethrin in grapes and grape process fractions after application of BAS 310 41 I under field conditions in Germany, 2004 2005/1014175
Guidelines:	EC 91/414 Annex II (Part A Section 6),EEC 1607/VI/97 rev. 2 10.06.1999,EEC 7029/VI/95 rev. 5,EEC 7525/VI/95 rev. 7,EEC 7035/VI/95 rev. 5,EEC 91/414 Annex III (Part A Section 8)
GLP:	yes (certified by Landesamt für Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Material and methods:

During the 2004 growing season, four field trials were conducted in grapes in different representative growing areas in Germany (Baden-Württemberg, Rheinland-Pfalz) in order to determine the magnitude and distribution of alpha-cypermethrin residues in the various intermediate and end products after processing. Two trials in the wine variety Spätburgunder (DU2/01/04 and DU2/02/04) and two trials the wine variety Portugieser (DU4/01/04 and DU4/02/04) were established.
Two of the trials consisted of two plots (DU2/01/04 and DU4/01/04), one untreated and one treated; the other two consisted of one treated plot each (DU2/02/04 and DU4/02/04).

A soluble concentrate formulation of alpha-cypermethrin was foliar applied 2 times at a target rate of 75 g a.s./ha for each application, resulting in a seasonal target rate of 150 g a.s./ha. Actual rates were within +/10 % of the nominal rate. This exaggerated rate was used in an attempt to generate residue levels sufficiently above the method limit of quantification (LOQ) in the raw agricultural commodity.

The applications were made 20-21 and 14 days before the anticipated harvest date using a spray volume of approximately 1000 I/ha. The growth stage at the last application was BBCH 85 (softening of berries).

Specimens of grapes were collected on the day of the last application for analysis and 14 days later for analysis of the raw agricultural commodity (RAC) and also for processing. RAC specimens were frozen within 24 hours of sampling, and remained frozen at or below -18°C, including during transportation, until analysis. The specimens for processing were maintained at ambient or cool temperatures until processing.
The specimens for processing were sent to the "Dienstleistungszentrum Ländlicher Raum – Rheinpfalz (DLR)" in Neustadt/Weinstraße. All specimens sent to the processing facility arrived within 24 hours of being sampled in good condition.

The following specimens resulted from the processing:
- must (rose and red wine making),
- stalks (red wine making)
- pomace (rose and red wine making)
- wine (rose and red wine making)
- yeast (rose and red wine making)
- raisins from dried grapes

The wine samples were stored at cellar temperatures. The samples of the intermediate products were taken at the relevant stages during the processing procedure and were frozen immediately. The analytical part of the study was performed at the Agricultural Research Center of BASF in Limburgerhof, Germany.
The specimens (RAC) as well as the processed commodity samples were analysed for alpha-cypermethrin by means of HPLC-MS/MS according to BASF method N° 567/0. The LOQ of the method was 0.01 mg/kg for all sample materials analysed.

As part of this study, a validation of method N° 567/0 in the matrix wine was performed. At fortification levels of 0.01 and 0.1 mg/kg, the recovery rates averaged at 95% (Transition 433-191) and at 98% (Transition 435-193).

Method performance was checked by determining the procedural recoveries in grape RAC and processed fractions.
The mean results of the procedural recoveries were 87 % at fortification levels between 0.01 mg/kg and 1.0 mg/kg with a standard deviation of 15.2 and a coefficient of variation of 17.4 %.

Findings:

No residues of alpha-cypermethrin at or above the method LOQ were detected in the untreated RAC specimens or in the processed fractions (must, stalks, pomace, wine, yeast and raisins) obtained from untreated RAC specimens.

Residues of alpha-cypermethrin in treated grape RAC collected at 14 days after the last application ranged from 0.05 to 0.12 mg/kg.

During the process of rose wine making, alpha-cypermethrin residues were found as follows:
in pomace after pressing, residues ranged between 0.12 and 0.22 mg/kg (concentration factors between 1.83 and 3.2). Relatively low residues were found in naturally cloudy must with values between 0.05 and 0.13 mg/kg (concentration factors between 0.83 and 1.6) which were further decreased after the following separation: in the separated must alpha-cypermethrin was found between 0.01 and 0.07 mg/kg (concentration factors between 0.2 and 0.8). Correspondingly, the waste product must deposit contained higher residues between 0.36 and 0.68 mg/kg which leads to concentration factors between 5.67 and 12.8.

In yeast deposit, too, concentrated residues between 0.16 and 0.77 mg/kg were found (concentration factors between 3.2 and 10.0). The final product rosé wine did not contain any alpha-cypermethrin above the limit of quantification (<0.01 mg/kg).

The residue situation in the red wine process was very similar: a slight concentration in the fractions stalks (factors 1.25 to 3.17) and crush (factors 1.42 to 2.2); low residues in the different must portions (naturally cloudy: factors 0.92 to 1.2, separated: factors 0.67 to 1.0).
As with rosé wine processing, the highest concentration was seen in the waste fractions pomace (factors 3.2 to 5.67), must deposit (factors 2.08 to 5.2) and yeast deposit (factors 5.83 to 10.8). The red wine did not show any alpha-cypermethrin above the LOQ.

Raisins are produced by drying which must lead to a concentration of residues. The residues found were between 0.17 and 0.38 mg/kg corresponding to concentration factors between 3.17 and 3.4. The waste fraction stalks which was removed after drying showed the highest residue concentration in this study (concentration factors 9.08 to 46.6).

The residue levels detected in the treated specimens and processed fractions as well as the calculated transfer factors are presented in the following table.

Table 2.1.2-1: Summary of alpha-cypermethrin residues in grapes and transfer factors - DocID 2005/1014175

3. for calculation purposes, < 0.01 was set 0.01

Wine processing procedure:
The amount of grapes was divided into two equal portions and then processed in two different ways (rose wine making and red wine making). The final fermentation was the same in both procedures.

Pressing and Separation (Rosé wine)
The grapes were crushed, and pressed on the same day. The must was sulphured with 50 mg SO_2/L, and left overnight for deposit of the must and subsequent separation.

Pressing and Separation (Red wine)
The grapes were stemmed and crushed on the same day. The total amount of the crush was sulphured with 50 mg SO_2/L and heated up to 70°C. After the heating the crush was pressed according to good wine making practice. The must was left to separate overnight.

Fermentation, Separation and Bottling (Rosé and Red Wine)
The separated must was immediately filled into two 25 L glass balloons and mixed with yeast. After fermentation and deposit of the young wine, the yeast was separated, and the young wine was mixed with 100 mg SO_2/L, and approx. 2 g Bentonit/L wine.
The wines of each repetition were mixed and filled into a balloon up to the bung. After another separation and ripening of the wine, a further separation was made, and the wine was filtered using EK filter units. Immediately after the filtration from each plot, 6 x 0.75 L bottles were filled. The bottles were stored in the cellar at cellar temperature until hand over to the Study Director.

Raisin processing procedure:
The grapes were dried in a dry chamber at 45 °C until raisin ripeness. Then the stalks were removed from the raisins.

Wine processing procedure flowcharts:

Figure 2.1.2-1: Rosé wine processing procedure flowchart - DocID 2005/1014175

Yield (%)	25.1	24.6	19.7	16.5

Conclusion:
The results of this processing study demonstrate clearly that residues in or on the raw agricultural commodity grapes are not transferred into the wine fraction during rosé or red wine making. Residues in the final products red or rosé wine were below the method LOQ (<0.01 mg/kg) in all cases. In raisins, residues are concentrated to a relatively high extent due to the drying process.

2.1.3 Estimation of MRL, HR and STMR for grape

For *grapes*, the following residue studies were considered (BASF DocIDs): 2005/1004977, 2005/1006474, 2005/1007589, 2005/1007591, 2006/1026853 and 2007/1008492.

The following residue values (PHI=7±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2005/1004977 (open field)	-	<0.05 (4x)
2005/1006474 (open field)	<0.05 (4x)	-
2005/1007589 (open field)	-	0.048, 0.051, 0.061, 0.069

Diehl M (2007): Study on the Residue Behaviour of BAS 310 I in Strawberry after Treatment with BAS 310 40 I under open field Conditions in Southern and Northern Europe, 2006; BASF Doc-ID 2007/1008493

Material and Methods:

In the years 2005 and 2006 a field program on strawberries was conducted in Belgium, France (Northern and Southern Region), Germany, Greece, Italy, the Netherlands, Spain and the United Kingdom under open field and glasshouse conditions to investigate the residue behaviour of alpha-cypermethrin after application of a 100 g a.s./L emulsifiable concentrate formulation (BAS 310 40 I).

During the 2005 growing season, eight trials were conducted in strawberries under open field conditions, four of them in the Northern European region (in Belgium, France, Germany and the United Kingdom) and four in the Southern European region (in France, Italy and Spain).
Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L, BAS 310 40 I), was foliar applied to strawberry plants in several variants. In four trials located in the Northern European region, the product was applied once at target rate of 12.5 g a.s./ha. This was compared to a second variant in which two applications were made at the same target application rate.
The last application took place at growth stages between 75 (50% of fruit have reached final size) and 89 (second harvest: more fruits coloured).
In four trials located in the Southern European region, a third variant was assayed in which BAS 310 40 I was applied to strawberry plants once at a target rate of 25 g a.s./ha at growth stages between 85 (first fruits have cultivar-specific colour) and 89 (second harvest: more fruits coloured).
Strawberry fruit specimens were collected directly after the last application as well as 1-2, 3 and 6-7 days thereafter. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF method No. 567/0, which has a limit of quantification of 0.01 mg/kg in all sample materials.

During the 2006 growing season, eight trials were conducted in strawberries under open field conditions, four of them in the Northern European region (in France, Germany, the Netherlands and the United Kingdom) and four in the Southern European region (in France, Greece, Italy and Spain).
Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L, BAS 310 40 I) was foliar applied to strawberry plants in several variants. In four trials located in the Northern European region, the product was applied once at target rate of 12.5 g a.s./ha . This was compared to a second variant in which two applications were made at the same target application rate.
The last application took place at growth stages between 85 (first fruits have cultivar-specific colour) and 87 (main harvest: more fruits coloured).
In four trials located in the Southern European region, a third variant was assayed in which BAS 310 40 I was applied to strawberry plants once at a target rate of 25 g a.s./ha at growth stages between 85 and 87.
Strawberry fruit specimens were collected directly after the last application as well as 1, 2-4 and 6-8 days thereafter. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF method No. 567/0, which has a limit of quantification of 0.01 mg/kg in all sample materials.

Eight glasshouse trials on strawberries were performed during the growing season 2005 in Belgium, France (Northern and Southern Region), Germany, Greece, Italy and Spain.
Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L, BAS 310 40 I), was foliar applied to strawberry plants at a target rate of 40 g a.s./ha. The growth stages of the plants were between 84 and 89 (second harvest: more fruits coloured).
Strawberry fruit specimens were collected directly after the last application as well as 3 and 7 days thereafter. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF method No. 567/0, which has a limit of quantification of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarized in Table 2.2.1-1 and Table 2.2.1-2.

_ underlined values were used for MRL calculation

Findings:
The residue studies in strawberries presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 2 applications with 12.5 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 3 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 3 days
- glasshouse GAP is a single application with 50 g a.s./ha with a PHI of 3 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions - 8 trials including both variants, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions - 8 trials, all conducted in the Southern European region
- one treatment at a target rate of 40 g a.s./ha under glasshouse conditions glasshouse - 8 trials, 4 conducted in the Northern European region and 4 conducted in the Southern European region

After one application at a target rate of 12.5 g a.s./ha under open field conditions, initial residues in strawberry fruit ranged between <0.01 mg/kg and 0.032 mg/kg and declined to <0.01 – 0.029 mg/kg and <0.01 – 0.022 mg/kg at 1 and 2-4 days after application, respectively. At the last sampling date, 6-8 days after application, only in one treated sample residues of 0.017 mg/kg were found (trial A/NF/I/05/80), while all other treated samples taken at the same sampling interval did not show residues above the limit of quantification (LOQ) of the analytical method (all <0.01).
After two applications at a target rate of 12.5 g a.s./ha under open field conditions, initial residues in strawberry fruit ranged between <0.01 mg/kg and 0.049 mg/kg and declined to <0.01 – 0.042 mg/kg, <0.01 – 0.031 mg/kg and <0.01 – 0.023 mg/kg at 1, 2-4 and 6-8 days after application, respectively.
After one application at a target rate of 25 g a.s./ha under open field conditions, initial residues in strawberry fruit ranged between <0.01 mg/kg and 0.038 mg/kg and declined to <0.01 – 0.030 mg/kg, <0.01 – 0.018 mg/kg and <0.01 – 0.022 mg/kg at 1-2, 3 and 6-8 days after application, respectively.
Under glasshouse conditions, initial residues between <0.01 mg/kg and 0.060 mg/kg were found in strawberry fruit after a single application of 40 g alpha-cypermethrin/ha. Residues declined to <0.01 – 0.054 mg/kg and <0.01 – 0.041 mg/kg 3 and 7 days after application, respectively.

Conclusion:

After treatment of strawberry plants with alpha-cypermethrin under open field conditions according to the proposed GAP, residues in strawberry fruit harvested at the target PHI were not higher than 0.05 mg/kg.

After treatment of strawberry plants with alpha-cypermethrin according to the GAP for glasshouse use, residues below 0.1 mg/kg can be expected in strawberry fruit.

2.2.2 Estimation of MRL, HR and STMR for strawberry

For *strawberries*, the following residue studies were considered (BASF DocIDs): 2007/1008489, 2007/1007935 and 2007/1008493.

The following residue values (PHI=3±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2007/1008489 (open field)	<0.01 (3x), 0.031	<0.01 (3x), 0.028
2007/1007935 (glasshouse)	<0.01 (4x), 0.029, 0.04, 0.048, 0.054	-
2007/1008493 (open field)	<0.01 (3x), 0.023	<0.01 (2x), 0.017, 0.018

2.3.1 Supervised residue trials in olive

Perny A (2005)

Full study reference

Perny A (2005): Study on the residue behaviour of alphacypermethrin (BAS 310 I) on olives after application of BAS 310 11 I under field conditions in Greece and Spain, 2003; BASF Doc-ID 2005/1004975

Schroth E (2005)

Full study reference

Schroth E (2005): Study on the residue behavior of Alpha-cypermethrin on olives after application of BAS 31041 I under field conditions in Spain and Greece, 2004; BASF Doc-ID 2005/1007582

Material and Methods:

In the years 2003 and 2004 a field program on olives was conducted in Greece and Spain.

During the growing season 2003, four trials were performed. An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L, BAS 310 11 I) was foliar applied to olive trees in several variants. In one variant, the product was applied once at target rate of 15 g a.s./ha . This was compared to a second variant in which two applications were made at the same target application rate.
The last application took place at growth stages between 78 (80% of fruits have reached final size) and 80 (fruit deep green colour becomes light green, yellowish.).
Olive fruit specimens were collected directly after the last application as well as 3-4, 6-8 and 14-15 days thereafter. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF method No. 546/0, which has a limit of quantification of 0.05 mg/kg in olives.

During the growing season 2004, four trials were performed. A soluble concentrate formulation of alpha-cypermethrin (100 g a.s./L, BAS 310 41 I) was foliar applied to olive trees in several variants. In one variant, the product was applied once at target rate of 15 g a.s./ha . This was compared to a second variant in which two applications were made at the same target application rate.
The last application took place at growth stages between 78 and 79 (fruit size about 90 % of final size; fruit suitable for picking green olives).
Olive fruit specimens were collected directly after the last application as well as 3, 7 and 13-14 days thereafter. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF method No. 567/0, which has a limit of quantification of 0.01 mg/kg in olives.

The trial data and residue results are summarized in Table 2.3.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in olives presented in the alpha-cypermethrin dossier were carried out in 2 different EU countries and provide data relevant to conditions in the Southern European region.

The following residue studies were presented:

- one or two treatments at a target rate of 15 g a.s./ha under open field conditions - 8 trials including both variants, all conducted in the Southern European region

The trials conducted during the growing season 2003 were analysed with a LOQ of 0.05 mg/kg, while the analytical method applied in the 2004 study had a LOQ of 0.01 mg/kg.

After one application at a target rate of 15 g a.s./ha, initial residues in olive fruit ranged between 0.01 mg/kg and 0.09 mg/kg and were <0.01 – 0.10 mg/kg, <0.01 – 0.09 mg/kg and <0.01 – 0.06 mg/kg at 3-4, 6-8 and 14-15 days after application, respectively.

After two applications at a target rate of 15 g a.s./ha, initial residues in olive fruit ranged between 0.02 mg/kg and 0.16 mg/kg and declined to <0.01 – 0.08 mg/kg, <0.01 – 0.09 mg/kg and <0.01 – 0.07 mg/kg at 3, 7 and 13-14 days after application, respectively.

Conclusion:

After two treatments with BAS 310 I at a target rate of 15 g a.s./ha, residues ranged between <0.01 – 0.09 mg/kg at 7 days after the last application.

Executive Summary

During the 2011 growing season a total of two trials (L110427 and L110428) were conducted in representative olive growing areas in Spain and Italy, in order to determine the residue level of alpha-cypermethrin after application of either BAS 310 40 I or BAS 310 55 I.
The test item BAS 310 40 I (100 g a.s./L BAS 310 I, EC) was foliar applied twice on plot 3, and the test item BAS 310 55 I (50 g a.s./L BAS 310 I, ME) was foliar applied twice on plot 2. Both of them were applied at 14±1 and 7±1 days before harvest and at a nominal rate of 15 g alpha-cypermethrin/ha in a nominal spray volume of 1000 l/ha using backpack spraying equipment.
Plot 4 was treated with a mixture of the test item BAS 310 55 I and a commercial bait applied at a concentration of 2%. The spray mixture was foliar applied twice at 14±1 and 7±1 days before harvest at a nominal rate of 9 g alpha-cypermethrin/ha in a low spray volume of 30 l/ha using backpack spraying equipment. Olive fruits were taken directly after the last application as well as 3, 7 and 14 days thereafter.
Specimens were analysed for alpha-cypermethrin using BASF method No. 567/0. The method has a limit of quantitation of 0.01 mg/kg.
Directly after the last of two applications of either BAS 310 55 I or BAS 310 40 I in a spray volume of 1000 L/ha, the residue of alpha-cypermethrin ranged between 0.03-0.16 mg/kg in olive fruit specimens. At 7±1 days, residues found were 0.08-0.19 mg/kg.
The analytical results obtained demonstrate that the treatment with two applications of BAS 310 55 I and BAS 310 40 I did not lead to significantly different residue results in the raw agricultural commodity at harvest.
Directly after the last of two applications of BAS 310 55 I with 2% bait in a spray volume of 30 L/ha the residue of alpha-cypermethrin ranged between 0.08-0.47 mg/kg in olive fruit specimens. At 7±1 days, residues found were 0.07-0.26 mg/kg.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 55 I (ME)
BAS 310 40 I (EC)
Lot/Batch #: 101198 BAS 310 55 I, 50 g/L alpha-cypermethrin
1209 BAS 310 40 I, 100 g/L alpha-cypermethrin
Purity:
CAS#: 67375-30-8 alpha-cypermethrin
Development code:
Spiking levels: 0.01-5.0 mg/kg

2. Test Commodity:

Crop: Olive
Type: Miscellaneous fruit
Variety: Picual, Cima di Melfi
Botanical name: *Olea europaea*
Crop parts(s) or processed
Commodity: Fruit
Sample size: 1.050-2.6 kg

B. STUDY DESIGN

1. Test procedure

Two residue trials in olive (L110427 and L110428) were conducted during the growing season 2011 in a representative olive growing area in Spain and Italy, respectively, to determine the residue level of alpha-cypermethrin after application of either BAS 310 40 I or BAS 310 55 I.
Both trials had a single untreated plot (Plot 1) and three treated plots (Plot 2, Plot 3, and Plot 4).
The test item BAS 310 40 I (100 g/L BAS 310 I, EC) was foliar applied twice on plot 3, and the test item BAS 310 55 I (50 g/L BAS 310 I, ME) was foliar applied twice on plot 2. Both of them were applied at 14±1 and 7±1 days before harvest and at a nominal rate of 15 g alpha-cypermethrin/ha in a nominal spray volume of 1000 l/ha using backpack spraying equipment.
Plot 4 was treated with a very low water volume of 30 l/ha and together with commercially available bait (mixing the product with water and the bait (2%)). Commercial bait for trial L110427 was named Hydrolyzed proteins 30% and was added to the mixture with BAS 310 55 I at a rate of 2%. Commercial bait for trial L110428 was named NUBAIT and was added to the mixture with BAS 310 55 I at a rate of 2%. The spray mixture was foliar applied twice at 14±1 and 7±1 days before harvest at a nominal rate of 9 g alpha-cypermethrin/ha in a low spray volume of 30 l/ha using backpack spraying equipment.

Olive fruits were taken directly after the last application as well as 3, 7 and 14 days thereafter. Olives collected 7 and 14 DALA were separated into flesh and stones and individual weights were recorded.

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin).
The residues of alpha-cypermethrin in olive specimens were extracted with acetonitrile/n-hexane. After centrifugation and a further partitioning step with n-hexane, the acetonitrile phase was cleaned up by solid-phase extraction on silica gel phase. Alpha-cypermethrin was eluted with dichloromethane. The solvent was evaporated, the residue was taken up into acetonitrile and diluted with acetonitrile/water (80:20, v/v) for LC/MS/MS determination. Final determination was performed by LC/MS/MS using the ammonium adduct of alpha-cypermethrin.
The limit of quantitation (LOQ) of the method is 0.01 mg/kg. The mean procedural recovery in olive fruit averaged 77±12% (mean ± RSD) for alpha-cypermethrin at fortification levels of 0.01 and 5.0 mg/kg.

Table 2.3.1-3: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in olive fruit

Matrix	Fortification Level (mg/kg)	Summary Recoveries		
		n	Mean (%)	RSD (%)
Method No. 567/0		alpha-cypermethrin		
Olive fruit	0.01	6	76	12
	5.0	8	78	13

II. RESULTS AND DISCUSSION

The residue levels of alpha-cypermethrin (BAS 310 I) in olive specimens taken directly after the last application (0 DALA) of BAS 310 55 I at 0.015 kg a.s./ha ranged between 0.03-0.15 mg/kg. In the specimens taken 3 DALA 0.08-0.10 mg/kg were found. The residues remained at this level in the PHI specimens (7 DALA) (0.08-0.13 mg/kg). At the last sampling (14 DALA) 0.06-0.09 mg/kg were found.

Residues found in olive specimens taken directly after the last application (0 DALA) of BAS 310 40 I at 0.015 kg a.s./ha contained residues of BAS 310 I in a range of 0.12 mg/kg to 0.16 mg/kg. After 3 days (3 DALA) residues ranged between 0.10-0.17 mg/kg. At 7 DALA 0.14-0.19 mg/kg were found. At the last sampling (14 DALA) the residue level lay at 0.12-0.13 mg/kg).

After the last treatment with BAS 310 55 I with 2% bait at a rate of 0.009 kg a.s.//ha, initial residues (0 DALA) ranged between 0.08-0.47 mg/kg which declined to 0.05-0.07 mg/kg after 3 days (3 DALA). At 7 days (7 DALA), residues between 0.07-0.26 mg/kg were detected. 14 days after the last treatment (14 DALA), residues ranged between 0.04-0.21 mg/kg.

In untreated samples residues of alpha-cypermethrin were not detectable.

An overall summary of the residues is given in the table below.

Table 2.3.1-4: Summary of residues of BAS 310 I in olive after application of BAS 310 55 I and BAS 310 40 I

Crop	Year	No. of Appl.	Application	DALA	BBCH	Residues Found (mg/kg)	
						Matrix	alpha-cypermethrin (BAS 310 I)
Olive / fruit	2011	2	BAS 310 55 I (ME) at 0.015 kg a.s./ha	0	85-88	fruit	0.03 – 0.15
				3	88-89		0.08 – 0.10
				7	88-89		0.08 – 0.13
				14	89		0.06 – 0.09
		2	BAS 310 40 I (EC) at 0.015 kg a.s./ha	0	85-88	fruit	0.12 – 0.16
				3	88-89		0.10 – 0.17
				7	88-89		0.14 – 0.19

				3	88-89		0.05 – 0.07
				7	88-89		0.07 – 0.26
				14	89		0.04 – 0.21

DALA = days after last application
BBCH = growth stage at respective sampling

III. CONCLUSION

Directly after the last of two applications of either BAS 310 55 I or BAS 310 40 I at a rate of 0.015 kg a.s./ha, the residues of alpha-cypermethrin ranged between 0.03-0.16 mg/kg in olive fruit specimens. At 7±1 days, residues found were 0.08-0.19 mg/kg.
The analytical results obtained demonstrate that the treatment with two applications of BAS 310 55 I and BAS 310 40 I did not lead to significantly different residue results in the raw agricultural commodity at harvest.
Directly after the last of two applications of BAS 310 55 I at a rate of 0.009 kg a.s./ha with 2% bait the residue of alpha-cypermethrin ranged between 0.08-0.47 mg/kg in olive fruit specimens. At 7±1 days, residues found were 0.07-0.26 mg/kg.

2.3.2 Processing studies in olive

Report:
Schulz H. 2007d
Study on the Residue Behaviour of Alpha-Cypermethrin in Olives and Processed Products after Treatment with BAS 310 41 I under Field Conditions in Spain, 2004
2007/1009604

Guidelines: EEC 91/414 Annex II (Part A Section 6),EEC 91/414 Annex III (Part A Section 8),EEC 1607/VI/97 rev. 2 10.06.1999,EEC 7029/VI/95 rev. 5,EEC 7525/VI/95 rev. 7,EEC 7035/VI/95 rev. 5

GLP: yes
(certified by Hessisches Ministerium für Umwelt, Laendlichen Raum und Verbraucherschutz)

Material and methods:

During the 2004 growing season, four field trials were conducted in olives in Spain in order to determine the magnitude and distribution of alpha-cypermethrin residues in the various intermediate and end products after processing.
Two of the trials (ALO/19/04 and ALO/21/04) consisted of two plots, one untreated and one treated; the other two consisted of one treated plot each (ALO/20/04 and ALO/22/04).

A soluble concentrate formulation of alpha-cypermethrin (BAS 310 41 I) was foliar applied 2 times at a target rate of 75 g a.s./ha for each application, resulting in a seasonal target rate of 150 g a.s./ha. Actual rates were within +/10 % of the nominal rate. This exaggerated rate was used in an attempt to generate residue levels sufficiently above the method limit of quantification (LOQ) in the raw agricultural commodity.

The applications were made 21 (± 1) and 7 (± 1) days before the anticipated harvest date using a spray volume of approximately 1000 I/ha. The growth stage at the last application was BBCH 88, i.e. fruit ripening.

Specimens of olives were collected on the day of the last application for analysis and 6-7 days later for analysis of the raw agricultural commodity (RAC) and also for processing. From every trial, 30 kg of olives were harvested to be processed to olive oil and 4 kg to fermented olives (7 days = PHI).

The olives were processed according to the BBA guideline Part IV 3 - 4 dated June 1990. In order to simulate common industrial procedures, the processing was performed in the pilot plant of Pilot Pflanzenöltechnologie Magdeburg e.V. (PPM) in D-39114 Magdeburg.

The following specimens resulted from the processing phases:

- wash water (olives), press cake, press water, oil meal, crude oil, n-hexane phase, slime/water mixture, soap, wash water (refining), filter cake, fatty acids and refined olive oil

- wash water (fermented olives), fermented olives, broth

The specimens were analysed for residues of alpha-cypermethrin using BASF method No. 567/0 for the determination of alpha-cypermethrin. The limit of quantification (LOQ) of the method was 0.01 mg/kg for all specimen materials analysed.

In order to validate the analytical method, control specimens were fortified with alpha-cypermethrin. In total, 33 fortified specimens were analysed. At fortification levels of 0.01, 0.1 and 1.0 mg/kg, the recovery rates averaged at 78.8 %. The standard deviation (SD) was 8.4% and the coefficient of variation (CV) was 10.6%.
The fortified specimens comprised both the olives and the processed products.

Findings:

Residues of alpha-cypermethrin in olives treated with BAS 310 41 I were determined. Specimens were collected immediately after application at growth stage 88 and 6 - 7 days later (7 days = PHI) at BBCH 89 (harvest maturity).

Directly after application, the alpha-cypermethrin residues in the olive specimens ranged from 0.154 to 0.478 mg/kg. They decreased substantially to 0.119 to 0.555 mg/kg in the specimens, sampled at 6 – 7 DAT.

In the olive oil processed specimens, the alpha-cypermethrin residues in wash water were between 0.048 and 0.124 mg/kg. After pressing of the olives, the alpha-cypermethrin residues were only found only in press cake, and no residues above the LOQ were found in press water. After extraction and distillation, the alpha-cypermethrin residues were concentrated in crude oil, whereas only small amounts were observed in oil meal and no residues above the LOQ were found in the extraction solvent n-hexane. In the processed products of the subsequent refining step, high alpha-cypermethrin residues were found in filter cake (0.473 – 1.78 mg/kg) and in the final product olive oil (1.11 – 3.42 mg/kg). In the other refining products, the residues were between < 0.01 mg/kg and 1.03 mg/kg.

In the fermentation processed products, alpha-cypermethrin residues were found in wash water (0.013 – 0.204 mg/kg) and in the consumer product fermented olives (0.190 – 0.607 mg/kg). No residues were observed in broth.

No residues at or above the LOQ were detected in the analysed untreated RAC specimens or in the processed fractions.

The residue levels detected in the treated specimens and processed fractions as well as the calculated transfer factors are presented in the following table. The transfer factors in the olive fruits (RAC) were set as 1.

Table 2.3.2-1: Summary of alpha-cypermethrin residues in olives and transfer factors - DocID 2007/1009604

Procedure for processing of olives to olive oil

Preparation of olives (RAC)

Cleaning

Dirt was removed from the field olives manually and discarded. Only the cleaned olives were used for processing.

Washing

The cleaned olives were washed manually with tap water. An aliquot of the wash water (olives) was taken as a specimen.

Crushing

The washed olives were crushed mechanically using a compression roll equipped with two coarse rollers. During the crushing process, the olive stones were crashed.

Preparation of crude oil

Pressing

The crushed olives were pressed using a platen press up to 280 bar to obtain press cake and oil/water mixture. An aliquot of the press cake was taken as specimen. The oil/water mixture was drained and allowed to separate in a container for 16 to 66 hours to obtain press oil and press water. The press oil was vacuum filtrated via Filtrasit, in order to remove solid particles (exception press oil of the olives of ALO/19/04, T, which was centrifuged). The filter residue and an aliquot of the press water were taken for residue analysis, the rest was discarded. The press oil was taken aside and combined with the extracted oil (see below) to obtain crude oil.

Drying of Press Cake

The press cake was dried in a vacuum drum dryer between room temperature up to 62 °C and between 61 and 140 mbar. The vacuum drying lasted between 1 hour and 1:30 hours.

Extraction and Distillation

The dried press cake was transferred into an extraction apparatus. After filling the solvent tank with 65 L of n-hexane, the heating supply was switched on, the heating supply was switched on (starting point of the extraction) while n-hexane was pumped in circle. After 2 hours, the extraction was stopped and the heating supply switched off.

The miscella was pumped into a 50 L distillation flask. The main part of the n-hexane was distilled off at 41 °C to 49 °C and between 410 mbar and 420 mbar. The oil remained in the distillation flask. The loss of n-hexane was compensated by adding fresh n-hexane into the tank. Thereafter, the second extraction run of the press cake was started. Then, the miscella was pumped into the distillation flask where the main part of n-hexane was distilled off. Finally, the oil phase was drained off, and the remaining n-hexane was removed in several batches using a rotary evaporator. The n-hexane phases were combined and an aliquot was taken as a specimen. The extracted oil and the press oil were combined to obtain crude oil. A specimen was taken for residue analysis. The rest of the crude oil was used for refining.

The extraction residue (oil meal) was transferred into plastic vats and allowed to stand at ambient temperature. The evaporation of n-hexane was supported by an exhaustive device. The weight of the oil meal was determined and a specimen taken for residue analysis. The remaining oil meal was discarded.

Refining

Hydration

About 1500 g of crude oil were heated-up to 60 °C using two infrared lamps under stirring, after which about 150 g of water (60 - 70 °C) were added. The mixture was heated up to about 85 °C and stirred for a further contact time of 45 min. and then allowed to rest until phase separation was achieved. The aqueous phase 1 containing voluminous precipitates was drained off and combined with the aqueous phase 2 obtained from the desliming step.

Desliming

The mixture obtained from hydration was heated up to 85 °C. When 60 °C were reached, between about 6 g of conc. phosphoric acid / water (1/1, v/v) were added drop by drop. At 85 °C, the mixture was stirred for a total time of 45 min. at 350 rpm. Then, about 150 g of water (100 °C) were added and the mixture was allowed to rest until slime separation was achieved. Because of the high phosphatite content, the deslimig step of the treated olives from trial ALO/21/04 was carried out twice. 2 x 151 g of water (100 °C) were added. The aqueous phase 2 was drained off by means of a discharge cock and combined with the aqueous phase 1 of the hydration step to obtain the slime/water specimen.

Neutralization

In order to determine the amount of sodium hydroxide necessary for the neutralization of the oil, the acid value was determined (see de-sliming). The oil was stirred and heated up to 90 °C. Then, a calculated volume of sodium hydroxide solution (7 %, T = ~ 90 °C) were added and the mixture stirred for 20 minutes while the temperature was kept at 90 °C. Subsequently, about 150 g of hot water were added and the stirring continued for a further 5 min. after which the mixture was allowed to cool down and rest for about 18 hours. The aqueous phase “soap” was taken as a specimen.
The acid value was between 0.06 and 0.11.

Washing

The oil phase obtained during neutralization was heated up to about 90 °C while stirred at 250 rpm and about 150 g of water at 100 °C were added. Subsequently, the mixture was stirred continuously for 20 min. and then allowed to rest until phase separation was achieved. Then, the aqueous phase was drained off. The pH value of the aqueous phase was determined and the washing procedure was repeated two to three times until pH 7 was achieved. The aqueous phases were taken as the specimen “wash water (refining)”.

Drying

The weight of the oil was determined after which 60 mg/kg of citric acid dissolved in water, were added while the oil was stirred at about 400 rpm and heated up to about 95 °C. Then, the remaining water was removed by applying a vacuum of 8 mm under stirring, while the temperature was kept at about 95 °C. This drying step lasted for 10 to 22 minutes.

Bleaching
The temperature of the dried oil was about 95 °C and 1 % of bleaching earth were added while the oil was stirred at 400 to 500 rpm. This mixture was stirred for 5 min. (contact time) at 95 °C. Then, vacuum of about 30 mm was applied and the mixture stirred for a further 30 min. after which time it was filtered through a cellulose acetate filter at about 80 °C by means of a nitrogen pressure of 3 bar. The filter cake was taken as a specimen.

Deodorization
Volatile substances in the bleached oil were removed by deodorization. During the deodorization process, condensed reaction products were trapped in a vacuum trap with dry-ice and taken as a specimen.
About 600 g of the bleached oil were deodorized at 1 mm. The oil was heated up. When 160 °C were reached, the water stream was allowed to pass through the oil at a rate of about 0.2 mL/minutes. When 240 °C were reached, this temperature was kept for a contact time of 20 minutes. Thereafter, the heating supply was switched off and the oil allowed to cool down. When 160 °C were reached in the cooling down phase, the water stream was stopped. The total water stream treatment lasted for 29 to 33 minutes. Subsequently, the oil was allowed to cool down to 80 °C (or lower). The deodorized oil was taken as a specimen.

This deodorization procedure was repeated once whereby the refined oils were combined.

Characterization of the refined olive oil specimens
In order to characterize the produced, refined olive oil specimens, fatty acid spectra were recorded at the processing facility using GC/FID. These data were not recorded according to GLP guidelines.

Procedure for processing of olives to fermented olives

Sorting
Blemished and rotten olives were sorted out from the field olives manually and discarded. Only the healthy olives were used for processing.

Washing
4 kg of olives were transferred into a stainless steel basin, after which about 2 kg of tap water was added. The olives were washed by hand for a few seconds and then allowed to stand for 24 hours. Thereafter, the olives were separated from the wash water using a sieve and subsequently rinsed with about 0.5 kg of fresh water, which was added to the water portion previously used. A specimen of the washing water was taken for residue analysis.

Fermentation
The washed olives were transferred into a glass bottle which was then filled up with sodium chloride solution (7 %). The fermentation process was started using Vege-Start (8 mg/kg olives). Thereafter, the glass bottles were closed using fermentation tubes with water as sealing liquid and stored protected from light for 3 months at room temperature.

After 3 months, the olives were separated from the broth using a sieve. Both the fermented olives and the broth were taken as specimens.

Conclusion:

The distribution of alpha-cypermethrin residues during processing of olives to olive oil and during the production of fermented olives was investigated.
In the olive oil fractions, the alpha-cypermethrin residues were concentrated in press cake (mean transfer factor = 2.32) and in crude oil (mean transfer factor = 11.68). In the subsequent refining steps, the alpha-cypermethrin residues were concentrated in slime/water mixture (mean transfer factor = 2.66), in filter cake (mean transfer factor = 3.99) and in the edible portion refined oil (mean transfer factor = 8.87). In the other processing products, the mean transfer factors were below 1.

In the fermentation process the alpha-cypermethrin residues were slightly concentrated in the fermented olives (mean transfer factor 1.44).

GLP: yes
(Agrolab: Helenic Republic Ministry of Finance, General Chemical State Laboratory, Division of Environment)

Material and methods:

Two trials were laid down in Greece in 1998. Olives trees were treated with alpha-cypermethrin 100 g a.s./l OESC and received six applications, 21 days apart at a target dose of 30 g a.s./hL. Spray volumes in the first trial (98-01-01) ranged between 125 - 133 L/ha and in the second trial (98-01-03) between 67 - 72 L/ha. The application method was foliar with 300 cc spray solution applied on 10% of the foliage of each tree of the plot. The last application was made in the first trial (98-01-01) at crop growth stage BBCH 81 (beginning of fruit colouring) and in the second trial (98-01-03) at BBCH 87 (fruit ripe for picking). Olives were sampled 0- (before last application), 0+ (immediately after last application), 14-15, 26-28, 40-42 and 56 days after the last application.
Specimens were frozen within 24 hours and remained frozen until residue analysis.

The processing phase of the olive oil production was conducted at Agrolab-Sindos Laboratories, VI.PE.TH Thessaloniki, Greece according to an internal AGROLAB method.

The analysis of the olive oil and olive specimens was conducted at Agrolab-Sindos Analytical Laboratories, VI.PE.TH Thessaloniki Greece. The analysis of the olive oil specimens was performed according to method AGROLABSOP-RAD.M.004.This method is applicable for the determination of alpha-cypermethrin residues in olive oil with a limit of quantification of 0.020 mg/kg.
The analysis of the olive fruit specimens was performed according to Sittingbourne Analytical
Method “Method for determination of residues of Alpha-cypermethrin in Crops-Gas Chromatographic Method”, SAMS 351-2.This method is intended for the determination of Alpha-cypermethrin residues in dry, oily and aqueous crops, with a limit of quantification of 0.01 mg/kg.
Method performance was checked by determining the procedural recoveries in olive and olive oil matrices. In olive fruit, the recovery rates averaged 102.4% with a standard deviation of 24.8 and a coefficient of variation of 24.2% at fortification levels of 0.01 mg/kg and 0.10 mg/kg. In olive oil, the recovery rates averaged 97.4% with a standard deviation of 15.9 and a coefficient of variation of 16.3% at fortification levels of 0.02 mg/kg and 1.00 mg/kg.

Findings:
No residues of alpha-cypermethrin were detected in the untreated specimens at or above the
limit of quantification of the analytical methods used.

Residues of alpha-cypermethrin were determined in the treated olive fruit (RAC) specimens and in the corresponding oil fractions 0- (before last application), 0+ (immediately after last application), 14-15, 26-28, 40-42 and 56 days after the last application.
The results are summarized below:

Procedure for processing of olives to olive oil

The processing was conducted separately for each individual specimen. The final oil sub-specimens were pooled at the end of the processing phase.
Before processing, the initial net weight of each specimen was recorded.

Homogenization
For the homogenization step, a Tecator homogenizer model 1094 was used. The olive fruits were homogenized for approximately 1-2 minutes. The pulp produced was weighed and transferred to the pressing device or stored in cool and dark conditions for later use. Pulp compression was conducted within 24 hours from pulp production. The homogenizer was thoroughly cleaned after each use.

Pulp pressing
The press device container was filled with pulp and was pressed for about 1 hour in 100 bar pressure in a hydraulic press device Karakasis Bros.

Juice extraction
The juice that was extracted, was weighed and collected into special plastic containers for centrifugation, while the cake was weighed and then discarded.

Centrifugation and olive – oil separation
The containers containing the extracted juice are centrifuged for 10 minutes at a 9000 rounds/min. speed in a Sigma 6-10 centrifugal device.
After centrifugation, the oily phase was collected in a plastic container and then was weighed and labelled. The water phase and the solid deposit were discarded.
At the end of the processing phase for each individual specimen, the processed oil sub-specimens were collected in the same vessel and labelled with the trial number, the specimen code number, the type of product after processing and the date of processing.
The samples were deep-frozen at <-18° C. At the end of the processing, the processed specimens were delivered to the analytical laboratory for residue analysis.

Guidelines: EEC 96/68,EEC 91/414 Annex II (Part A Section 6),EEC 91/414 Annex III (Part A Section 8),EEC 7029/VI/95 rev. 5

GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Material and methods:

One trial was laid down in Greece in 1999 in which olive trees were treated with alpha-cypermethrin 100 g a.s./L OESC. The olive trees received 6 applications, 21-26 days apart at a dose rate of 3 g a.s./hL with spray volumes ranging between 998 and 1001 L/ha. The crop growth stage at the final application was BBCH 85 (advanced ripening). Olive specimens were sampled at 0- and 0+ days after treatment no. 6 (just before and just after the final application), and then at 14, 28, 42 and 56 days after the final treatment. At each sampling, separate specimens were taken for olive oil and olive fruit analysis.

The specimens for processing into olive oil were sent to AGROLAB in Thessaloniki (Greece) at ambient temperature. There, the olive oil was extracted from the olives and was then frozen prior to despatch to the Product Research and Development Laboratory (PRDL), Cyanamid Agriculture Ltd., Gosport, Hampshire, UK, for analysis.

The specimens taken for olive fruit analysis were frozen within 24 hours of being taken and remained frozen, including during transportation, until analysis.

The analysis of the specimens was conducted at PRDL according to method RLA 12594.01.
Procedural recoveries performed during the analysis of the specimens from this study, AL-HE-99-530, confirmed the validity of the method.
In olive fruit, a recovery of 70% was found at a fortification level of 0.05 mg/kg. In olive oil, the recovery was 83% at 0.5 mg/kg.

Findings:

No residues, at or above the limit of quantification, of alpha-cypermethrin were detected in the untreated olive fruit and olive oil specimens.

Residue levels in the treated olive oil specimens ranged between 0.24 and 0.79 mg/kg. Residue levels in the treated olive fruit specimens ranged between <0.05 and 0.15 mg/kg.

The results are summarized in the following table:

Table 2.3.2-7: Summary of alpha-cypermethrin residues in olives and transfer factors - DocID AL-714-001

1) The residue in the whole fruit can be calculated as follows:
Weight of flesh = 75% of whole fruit 75% of 0.15 mg/kg = 0.11 mg/kg = total residues in the whole fruit.
(The actual residue in flesh of <0.05 mg/kg is taken as 0.05 mg/kg for the purposes of the calculation.)

Procedure for processing of olives to olive oil

The processing was conducted separately for each individual specimen. The final oil sub-specimens were pooled at the end of the processing phase.
Before processing, the initial net weight of each specimen was recorded.

Homogenization
The olive fruits were homogenized in a Tecator 1094 homogenizer. The stones were then removed from the pulp produced.

Pulp pressing
The pulp was pressed in a laboratory hydraulic press at 100 bar pressure and the juice that was extracted was collected and equally distributed in six centrifugation vessels of 300 ml capacity each.

Centrifugation and olive – oil separation
The juice was then centrifuged at 9000 rpm for ten minutes and the overlaying fraction of oil was removed from each vessel using a pipette. The oil produced in each centrifugation was weighed and collected in a plastic container.
Because specimens were too large to be processed in one individual processing step, they were processed in smaller quantities (sub-specimens) and then mixed in one individual container.
The processed specimens were packed in plastic bags and labelled.
The samples were stored deep-frozen at <-18° C. At the end of the processing, the processed specimens were delivered to the analytical laboratory for residue analysis.

Conclusion:

After treatment of olive trees with alpha-cypermethrin, a residue concentration was observed in the oil fraction. The transfer factors found in this study ranged between >1.40 – >15.80.

2.3.3 Estimation of MRL, HR and STMR for olive

For *olives*, the following residue studies were considered (BASF DocIDs): 2005/1004975, 2005/1007582 and 2012/1157548.

The following residue values (PHI=7±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Southern Europe (S-EU) [mg/kg]
2005/1004975 (open field)	<0.05 (4x)
2005/1007582 (open field)	<0,01, 0.04 (2x), 0.09
2012/1157548 (open field)	0,14, 0,26
OECD-MRL-calculation (open field)	**0.4 (n=10, STMR=0.05, HR=0.26)**

_ underlined values were used for risk assessment purposes

2.4 Potato

Residue data from supervised trials in potatoes were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.4-1: Number of residue trials conducted in potato per geographical region and vegetation period

Oxspring S (2007)

Full study reference

Oxspring S (2007): Study on the residue behaviour of alpha-cypermethrin in potato after treatment with BAS 310 40 I under field conditions in Northern and Southern Europe during 2006; BASF DocID 2007/1007945

Material and Methods:

In the years 2001, 2004, 2005 and 2006 a residue program in potatoes was conducted in representative potato growing areas in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom.

Eight residue decline trials were conducted in potatoes in the United Kingdom, Germany, Spain, France (North and South), Italy, Greece and the Netherlands during 2001. Potato plants were treated with a 150 g/kg wettable granule formulation (WG; BAS 310 08 I) formulation of alpha-cypermethrin. Separate plots of potatoes were treated with either a single application at a target rate of 15 g a.s./ha or two applications at a target rate of 15 g a.s./ha. The single applications were intended to be made 28 days before harvest. The growth stage of the potato plants at application was between 32 (20% of plants meet between rows) and 91(beginning of leaf yellowing). Specimens of potatoes were taken immediately after the last application, 6-8, 20-22, 28-29 and 34-36 days after the final application.
The specimens were analysed for residues of BAS 310 I using BASF Agro Research method RLA 12513.03V (GC-ECD) which has a limit of quantitation of 0.05 mg/kg for potatoes.

During the 2004 growing season, two field trials were conducted in Italy and Greece in order to determine the residues of alpha-cypermethrin in potatoes after application of a 100 g a.s./L soluble concentrate formulation (BAS 310 41 I).
The product was foliar applied to potatoes in different amounts: In the first variant, one application was done at a target rate of 15 g a.s./ha. This was compared to a second variant, consisting of two treatments at a target rate of 15 g a.s./ha performed at the same application rate. The growth stage of the potato plants was 49 (skin set complete: (skin at apical end of tuber not removable with thumb) 95% of tubers in this stage) at the last application. Potato tuber specimens were sampled directly after the last application as well as 3, 7-8 and 14 days thereafter.
The samples were analysed for alpha-cypermethrin by means of HPLC-MS/MS according to BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg.

During the 2005 growing season, alpha-cypermethrin was tested in potato at eight locations. Different application schemes were compared: In the Northern European trials performed in the United Kingdom, France, Germany and the Netherlands an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I) was foliar applied once or twice at a target rate of 12.5 g a.s./ha to separate plots of potato plants. The growth stage of the potato plants was between 46 (60% of total final tuber mass reached) and 69 (end of flowering in the first inflorescence) at the last application.
In the four Southern European trials performed in France, Italy, Spain and Greece one single treatment at a target rate of 25 g a.s./ha was foliar applied to potato plants. The growth stage of the potato plants was between 42 (20% of total final tuber mass reached) and 47 (70% of total final tuber mass reached) at application. Potato tuber specimens were collected directly after the last application as well as 7, 14 and 20-22 days thereafter. They were analysed for alpha-cypermethrin by means of HPLC MS/MS with BASF analytical method No. 567/0 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, alpha-cypermethrin was tested in potato at eight locations. Different application schemes were compared: In the Northern European trials performed in France, Denmark, Germany and the United Kingdom an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I) was foliar applied once or twice at a target rate of 12.5 g a.s./ha to separate plots of potato plants. The growth stage of the potato plants was between 45 (50% of total final tuber mass reached) and 71 (10% of berries in the first fructification have reached full size (main stem)) at the last application.
In the four Southern European trials performed in France, Italy, Spain and Greece one single treatment at a target rate of 25 g a.s./ha was foliar applied to potato plants. The growth stage of the potato plants was between 46 (60% of total final tuber mass reached) and 83 at application. Potato tuber specimens were collected directly after the last application as well as 7, 14 and 21 days thereafter. They were analysed for alpha-cypermethrin by means of HPLC MS/MS with BASF method No. 567/0 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.4.1-1.
.

Table 2.4.1-1: Residues in potatoes

GAP for EU-N is 1-2 applications with 15 g a.s./ha at infestation as an overall spray, PHI = 7 days
GAP for EU-S is 1 application with 30 g a.s./ha at infestation as an overall spray, PHI = 14 days

_ underlined values were used for MRL calculation

Findings:

The residue studies in potatoes presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 14 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha–8 trials including both variants, all conducted in the Northern European region
- one or two treatments at a target rate of 15 g a.s./ha–10 trials including both variants, 4 conducted in the Northern European region and 6 conducted in the Southern European region
- one treatment at a target rate of 25 g a.s./ha conditions–8 trials conducted in the Southern European region

In all trials presented above no residues above the method LOQ (0.05 mg/kg for the 2001 study-8 trials with either one or two applications at 15 g a.s./ha; 0.01 mg/kg for all other trials) were found in any of the treated potato tuber samples, regardless of rate or sampling interval.

Conclusion:

In the years 2001, 2004, 2005 and 2006 a residue program in potatoes was conducted in representative potato growing areas in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom.
A total of 26 trials were performed that support the proposed GAPs for the Northern and Southern European region. In all trials no residues above the method LOQ (0.05 mg/kg for the 2001 study-8 trials with either one or two applications at 15 g a.s./ha; 0.01 mg/kg for all other trials) were found in any of the treated potato tuber samples, regardless of rate or sampling interval.

Executive Summary

During the 2007 growing season, a total of four trials were conducted on potato in order to determine the magnitude of residues of active ingredient(s) in or on Raw Agricultural Commodities (RAC).
Plot 101: Untreated (control)
Plot 102: BAS 370 00 I, a SL formulation of alpha-cypermethrin (25 g/L) and acetamiprid (100 g/L), was applied twice at the rate of 500 mL/ha, in order to determine the magnitude of the residues of active ingredient in or on Raw Agricultural Commodities (RAC).
Plot 103: BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g/L), was applied twice at the rate of 125 mL/ha, in order to determine the magnitude of the residues of active ingredient in or on Raw Agricultural Commodities (RAC).
Plot 104: BAS 9111 0 I, a WP formulation of acetamiprid (200 g/kg), was applied twice at the rate of 250 g/ha, in order to determine the magnitude of the residues of active ingredient in or on
Raw Agricultural Commodities (RAC).
In context of this summary, only the results of alpha-cypermethrin (plot 102 & plot 103) are reported.
Potato specimens were collected immediately after the last application and 7 ± 1, 14 ± 1 and 21 ± 1 day after the last application.
The specimens were analyzed according to BASF analytical method number 567/0 for alpha-cypermethrin and to Nippon Soda CO. LTD method RD-9991 N2 for acetamiprid.
Both methods have a limit of quantification of 0.01 mg/kg in all sample materials. Procedural recoveries averaged 92% for alpha-cypermethrin and 84% for acetamiprid, respectively, at fortification levels between 0.01 and 1 mg/kg.
For alpha-cypermethrin, at all samplings from plot 102 and 103, in potato tubers no residues above the LOQ (0.01 mg/kg) were determined.

I. MATERIAL AND METHODS

Botanical name:	*Solanum tuberosum* L.
Crop parts(s) or processed commodity:	Potato tubers
Sample size:	min. 2.0 kg

B. STUDY DESIGN

1. Test procedure

During the 2007 growing season, a total of four trials were conducted on potato in order to determine the magnitude of residues of active ingredient(s) in or on Raw Agricultural Commodities (RAC).

Plot 101: Untreated (control)

Plot 102: BAS 370 00 I, a SL formulation of alpha-cypermethrin (25 g/L) and acetamiprid (100 g/L), was applied twice at the rate of 500 mL/ha, in order to determine the magnitude of the residues of active ingredient in or on Raw Agricultural Commodities (RAC).

Plot 103: BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g/L), was applied twice at the rate of 125 mL/ha, in order to determine the magnitude of the residues of active ingredient in or on Raw Agricultural Commodities (RAC).

Plot 104: BAS 9111 0 I, a WP formulation of acetamiprid (200 g/kg), was applied twice at the rate of 250 g/ha, in order to determine the magnitude of the residues of active ingredient in or on

Raw Agricultural Commodities (RAC).

In context of this summary, only the results of alpha-cypermethrin (plot 102 & plot 103) are reported.
Potato specimens were collected immediately after the last application and 7 ± 1, 14 ± 1 and 21 ± 1 day after the last application.

Table 2.4.1-2: Target application rates and timings for potatoes

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2007	4	2	F	BAS 370 00 I (SL)	alpha-cypermethrin acetamiprid	0.0125 0.05	400	21±1 DBH 14±1 DBH
			F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125		
			F	BAS 9111 0 I (WP)	acetamiprid	0.05		

DBH = Days before harvest

2. Description of analytical procedures

The specimens were analyzed according to BASF analytical method number 567/0 for alpha-cypermethrin and to Nippon Soda CO. LTD method RD-9991 N2 for acetamiprid.
Both methods have a limit of quantification of 0.01 mg/kg in all sample materials. Procedural recoveries averaged 92% for alpha-cypermethrin and 84% for acetamiprid, respectively, at fortification levels between 0.01 and 1 mg/kg.
Alpha-cypermethrin: the residues of alpha-cypermethrin are extracted from plant matrices using a mixture of methanol, water and HCl 2 mol/L. For clean-up a liquid/liquid partition against cyclohexane is used. The final determination of alpha-cypermethrin is performed by LC/MS/MS. The limit of quantification (LOQ) ofthe method is 0.01 mg/kg.
Acetamiprid: The residues of acetamiprid are extracted from plant matrices using a mixture of methanol and water. For clean-up a liquid/liquid partition against dichloromethane is used. The final determination of acetamiprid is performed by LC/MS/MS. The limit of quantification (LOQ) ofthe method is 0.01 mg/kg.

Table 2.4.1-3: Summary of recoveries of alpha-cypermethrin and acetamiprid in potato tubers

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
potato tubers	0.01 / 1.0	6	92	7	6
RD-9991 N2		acetamiprid			
potato tubers	0.01 / 1.0	5	84	4	3

II. RESULTS AND DISCUSSION

For alpha-cypermethrin, at all samplings from plot 102 and 103, in potato tubers no residues above the LOQ (0.01 mg/kg) were determined.

An overall summary of the residues is given in the table below.

Table 2.4.1-4: Summary of residues of BAS 310 I in potato tubers from trials according to critical GAP after application of BAS 310 40 I and BAS 370 00 I

Crop	Year	No. of Appl.	Application	DALA	BBCH	Residues Found (mg/kg)	
						Matrix	Alpha-Cypermethrin (BAS 310 I)
Potato	2007	2	BAS 370 00 I (SL)	0	44-68	tubers	<0.01
				7±1	45-75		<0.01
				14±1*	47-85		<0.01
				21±1	48-95		<0.01
			BAS 310 40 I (EC)	0	44-68	tubers	<0.01
				7±1	45-75		<0.01
				14±1*	47-85		<0.01
				21±1	48-95		<0.01

DALA = days after last application
BBCH = growth stage at respective sampling
* harvest

III. CONCLUSION

At all sampling events (between 0 and 21 days after the last application of either formulation BAS 370 00 I or BAS 310 40 I), in potato tuber specimens no residues of alpha-cypermethrin above the LOQ (0.01 mg/kg) were determined.

Guidelines:	EEC 87/18 (18 December 1986), International guidelines for distribution and pesticides application AEPLA FAO 1985, EC 1107/2009 of the European Parliament and of the Council of 21 Oct 2009, EEC 79/117, EEC 91/414, EEC 7029/VI/95 rev. 5 Appendix B
GLP	yes

Executive Summary

During the growing season of 2011, a total of four trials with potato was conducted in Germany, The United Kingdom, Italy and Spain, to determine the magnitude and decline of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC). Therefore two solo formulations BAS 310 55 I (50 g/L BAS 310 I, ME) and BAS 310 40 I (100 g/L BAS 310 I, EC) were applied twice to the treated plots at a rate equivalent of 0.015 kg a.s./ha in a nominal spray volume of 200 l/ha at 21±1 and 14±1 days before harvest. The applications were made at crop stages between BBCH 43 and 48.

Potato tuber specimen were taken for analysis directly after the last application as well as 7-8, 13-15 and 20-21 days thereafter. Specimens were analysed for alpha-cypermethrin using BASF method No. 567/0. The method has a limit of quantitation of 0.01 mg/kg.

At all the field trials, residues of alpha-cypermethrin in all treated potato samples were below the LOQ (< 0.01 mg/kg) after treatment with both formulations at all sampling times.

The analytical results obtained demonstrate that the treatment with two applications of BAS 310 55 I and BAS 310 40 I did not lead to different residue results in the raw agricultural commodity at harvest.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 55 I (ME)
BAS 310 40 I (EC)

B. STUDY DESIGN

1. Test procedure

During the growing season of 2011, a total of four trials with potato was conducted in Germany, The United Kingdom, Italy and Spain, to determine the magnitude and decline of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC). Therefore two solo formulations BAS 310 55 I (50 g/L BAS 310 I, ME) and BAS 310 40 I (100 g/L BAS 310 I, EC) were applied twice to the treated plots at a rate equivalent of 0.015 kg a.s./ha in a nominal spray volume of 200 l/ha at 21±1 and 14±1 days before harvest. The applications were made at crop stages between BBCH 43 and 48.
Potato tuber specimen were taken for analysis directly after the last application as well as 7-8, 13-15 and 20-21 days thereafter.

Table 2.4.1-6: Target application rates and timings for potato

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2008	4	2	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.015	200	1st appl.: 21±1 DBH 2nd appl.: 14±1 DBH
		2	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.015	200	1st appl.: 21±1 DBH 2nd appl.: 14±1 DBH

1) 2 litres of water plus 1 litre of product to make up a spray volume of 3 litres
2) DBH: days before harvest

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin).

The residues of alpha-cypermethrin in potato specimens were extracted using a mixture of methanol/water/hydrochloric acid (70:25:5, v/v/v). After centrifugation, an aliquot of the extract was partitioned into cyclohexane. An aliquot of the cyclohexane phase was evaporated and the residue was taken up into methanol/water (80:20, v/v). The final determination of alpha-cypermethrin was performed by LC-MS/MS using the ammonium adduct of alpha-cypermethrin. The limit of quantitation (LOQ) of the method is 0.01 mg/kg. The mean procedural recovery averaged 103±7% (mean±RSD) for alpha-cypermethrin at fortification levels of 0.01 mg/kg -5.0 mg/kg.

Table 2.4.1-7: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in potato

Matrix	Fortification Level (mg/kg)	Summary Recoveries		
		n	Mean (%)	RSD (%)
Method No. 567/0		alpha-cypermethrin		
Potatoes	0.01	5	99	9
	5.0	5	107	3

II. RESULTS AND DISCUSSION

The residue levels of alpha-cypermethrin (BAS 310 I) in potato specimens taken directly after the last application of BAS 310 55 I (0 DALA) and at 7-8, 13-15 and 20-21 DALA were all below the limit of quantitation of the analytical method (LOQ, <0.01 mg/kg).
Residues found in potato specimens after the application of BAS 310 40 I lead to similar residue results of alpha-cypermethrin, with all residue results at 0, 7-8, 13-15 and 20-21 DALA being below the LOQ. The analytical results obtained demonstrate that the treatment with two applications of BAS 310 55 I and BAS 310 40 I did not lead to different residue results in the raw agricultural commodity at harvest.
In all untreated samples from trials L110423 through L110426, residues of alpha-cypermethrin were below the LOQ (<0.01 mg/kg).
An overall summary of the residues is given in the table below.

Table 2.4.1-8: Summary of residues of BAS 310 I in potato after application of BAS 310 55 I and BAS 310 40 I

Crop	Year	No. of Appl.	Application	DALA	BBCH	Residues Found (mg/kg)	
						Matrix	alpha-cypermethrin (BAS 310 I)
Potato	2011	2	BAS 310 55 I (ME)	0	47-48	tuber	< 0.01
				7-8	47-48		< 0.01
				13-15	48-49		< 0.01
				20-21	48-49		< 0.01
		2	BAS 310 40 I (EC)	0	47-48	tuber	< 0.01
				7-8	47-48		< 0.01
				13-15	48-49		< 0.01
				20-21	48-49		< 0.01

DALA = days after last application
BBCH = growth stage at respective sampling

III. CONCLUSION

At all the field trials, residues of alpha-cypermethrin in all treated potato samples were below the LOQ (< 0.01 mg/kg) after treatment with both formulations at all sampling times.
The analytical results obtained demonstrate that the treatment with two applications of BAS 310 55 I and BAS 310 40 I did not lead to different residue results in the raw agricultural commodity at harvest.

2.4.2 Estimation of MRL, HR and STMR for potato

For *potato*, the following residue studies were considered (BASF DocIDs): 2006/1026846, 2007/1007945, 2008/1002704, and 2012/1157550.

The following residue values (PHI=7±1 days for EU-N or PHI=14±1 days for EU-S) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026846	<0.01 (4 x)	<0.01 (4 x)
2007/1007945	<0.01 (4 x)	<0.01 (4 x)

Anonymous (2006): Residue behaviour of Alpha-Cypermethrin in/on fennel, curly cale, cucumbers, carrots, radies, celery, celeriac and bunshing or green onions after outdoor application of Fastac SC (SC 100) in Germany, 2005; BASF DocID 2006/1029533

Material and Methods:

In the years 2004 and 2005 a residue program in carrots was conducted in representative carrot growing areas in Germany.

Three residue decline trials were conducted in carrots in Germany during 2004. Carrots plants were treated with a 100 g a.s./L soluble concentrate formulation (BAS 310 41 I). Plots of carrots were treated with two applications at a rate of 12.5 g a.s./ha. The last application was intended to be made 14 days before harvest. Specimens of carrots were taken immediately after the last application, 3, 7 and 14 days after the final application.
The specimens were analysed for residues of BAS 310 I using DFG method S19 which has a limit of quantitation of 0.01 mg/kg for carrots.

During the 2005 growing season, six field trials were conducted in Germany in order to determine the residues of alpha-cypermethrin in carrots after application of a 100 g a.s./L soluble concentrate formulation (BAS 310 41 I). Plots of carrots were treated with two applications at a rate of 12.5 g a.s./ha. The growth stage of the carrot plants was between 6-7 leaves and BBCH 77. Carrot specimens were sampled directly after the last application as well as 3, 7 and 14-15 days thereafter.

The samples were analysed for alpha-cypermethrin by means of HPLC-MS/MS according to BASF analytical method No. 567/0, which has a limit of quantitation of 0.005 mg/kg.

The trial data and residue results are summarised in Table 2.5.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in carrots presented in the alpha-cypermethrin dossier were carried out in 1 EU countries and do not provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for Germany: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 3-7 days

The following residue studies were presented:

- two treatments at a target rate of 12.5 g a.s./ha–9 trials, all conducted in Germany

In all trials presented above no residues above the method LOQ (0.01 mg/kg) were found in any of the treated carrot samples.

Conclusion:

In the years 2004 and 2005 a two residue studies in carrots were conducted in Germany. A total of 9 trials were performed that support the proposed GAP for Germany. In all trials no residues above the method LOQ (0.01 mg/kg) were found in any of the treated carrot samples.

2.5.2 Estimation of MRL, HR and STMR for carrot

For *carrot*, the following residue studies were considered (BASF DocIDs): 2005/1035294 and 2006/1029533.

The following residue values (PHI=3-7 days) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

2.6.1 Supervised residue trials in onions

Jones G (2007)

Full study reference

Jones G (2007): Study on the residue behaviour of BAS 310 I in bulb onion after treatment with BAS 310 40 I under field conditions in Northern Europe during 2005; BASF DocID 2006/1026854

Diehl M (2007)

Full study reference

Diehl M (2007): Study on the residue behaviour of BAS 310 I in onion after treatment with BAS 310 40 I under open field conditions in Northern Europe, 2006, BASF DocID 2007/1008499

Material and Methods:

A residue program in bulb onions was conducted in the years 2005 and 2006 in representative onion growing areas in France (Northern European region), Germany, the Netherlands and the United Kingdom under open field conditions.

During the 2005 growing season, four trials were conducted in bulb onions in France (Northern European region), the Netherlands and the United Kingdom. Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L, BAS 310 40 I) was foliar applied to onion plants in two variants. In one variant, the product was applied once at target rate of 12.5 g a.s./ha. This was compared to another variant in which two applications were made at the same target rate. The last application took place at growth stages between 47 (bolting begins; in 10% of the plants leaves bent over) and 48 (leaves bent over in 50% of plants). Onion bulb specimens were collected directly after the last application as well as 3-4, 7 and 14 days thereafter. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, four trials were conducted in bulb onions in France (Northern European region), Germany and the Netherlands. Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L, BAS 310 40 I) was foliar applied to onion plants in two variants. In one variant, the product was applied once at target rate of 12.5 g a.s./ha. This was compared to another variant in which two applications were made at the same target rate. The last application took place at growth stages between 44 (bulb enlarges) and 47 (bolting begins; in 10% of the plants leaves bent over). Onion bulb specimens were collected directly after the last application as well as 3-4, 7-8 and 14-15 days thereafter. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.6.1-1.

Table 2.6.1-1: Residues in onions

_ underlined values were used for MRL calculation

Findings:

The residue data presented in the alpha-cypermethrin dossier were carried out in 4 different EU countries and provide data relevant to conditions in the Northern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha–8 trials including both variants, all conducted in the Northern European region

After one application at a target rate of 12.5 g a.s./ha, no residues above the limit of quantitation of the analytical method (LOQ, 0.01 mg/kg) were found in treated onion bulbs sampled 0–15 days after application. The only exception was one isolated finding at the LOQ (0.012 mg/kg) 3 days after application in trial AF/8827/BA/1. Residues in all other treated bulb samples taken from the same plot 0, 7 and 14 days after application were <0.01 mg/kg.

After two applications at a target rate of 12.5 g a.s./ha, initial residues in onion bulbs ranged between <0.01–0.017 mg/kg. Residues declined to <0.01-0.014 mg/kg and <0.01-0.010 mg/kg after 3-4 and 7-8 days and were below the LOQ (<0.01 mg/kg) in all trials 14-15 days after the last application.

Conclusion:

A residue program in bulb onions was conducted in the years 2005 and 2006 in representative onion growing areas in France (Northern European region), Germany, the Netherlands and the United Kingdom under open field conditions. In 8 trials supporting the proposed GAP for the Northern European region, residues in onion bulbs ranged between <0.01-0.010 mg/kg at the target PHI of 7±1 days.

2.6.2 Estimation of MRL, HR and STMR for onions

For *onions*, the following residue studies were considered (BASF DocIDs): 2006/1026854 and 2007/1008499.

The following residue values (PHI=7±1 days) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Material and Methods:

During the growing seasons 2005 and 2006, a residue program in sweet pepper was conducted in different representative pepper growing areas in Belgium, France (Southern European region), Greece, Italy, and Spain under open field and glasshouse conditions.

In the year 2005, four field trials were conducted in France (Southern European region), Greece, Italy and Spain to determine the residue level of alpha-cypermethrin after application as a emulsifiable concentrate (EC 100 g a.s./L; BAS 310 40 I). The product was foliar applied once at a target rate of 25 g a.s./ha 7 days before expected harvest. The growth stages of the plants at application were between 68 (8^{th} inflorescence: first flower open) and 87 (70% of fruits show typical fully ripe colour).
Specimens of fruit were collected at the day of application from each plot as well as 2-3, 6-7 and 13-14 days thereafter.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS using BASF method no. 567/0 with a limit of quantification of 0.01 mg/kg in all sample materials.

In the year 2006, four field trials were conducted in France (Southern European region), Greece, Italy and Spain to determine the residue level of alpha-cypermethrin after application as a emulsifiable concentrate (EC 100 g a.s./L; BAS 310 40 I). A single treatment was applied at a target rate of 25 g a.s./ha 7 days before expected harvest. The growth stages of the plants at application were between 72 (2nd fruit has reached typical size and form) and 87 (70% of fruits show typical fully ripe colour).
Specimens of fruit were collected at the day of application from each plot as well as 3-4, 7-8 and 13-14 days thereafter.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS using BASF method no. 567/0 with a limit of quantification of 0.01 mg/kg in all sample materials.

Six glasshouse trials in sweet pepper were performed during the growing season 2005 in Belgium, France (Southern European region), Greece, Italy and Spain.
Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L; BAS 310 40 I) was foliar applied to sweet pepper plants once at a target rate of 40 g a.s./ha. The growth stages of the plants were between 72 (2nd fruit has reached typical size and form) and 89 (Fully ripe: fruits have typical fully ripe colour) at application. Samples of sweet pepper fruit were collected immediately after application as well as 3, 7 and 14 days afterwards.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS using BASF method no. 567/0 with a limit of quantification of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarized in Table 2.7.1-1 and Table 2.7.1-2.

_ underlined values were used for MRL calculation

Findings:

The residue trials in sweet pepper presented in the alpha-cypermethrin dossier were carried out in 5 different EU countries and provide data relevant to conditions in the Southern European region and to glasshouse conditions.
The proposed GAP is

- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days under open field conditions
- glasshouse GAP is a single application with 50 g a.s./ha applied at infestation as an overall spray with a PHI of 3 days

The following residue studies were presented:

- one treatment at a target rate of 25 g a.s./ha under open field conditions; 8 trials, all conducted in the Southern European region
- one treatment at a target rate of 40 g a.s./ha under glasshouse conditions – 6 trials, 5 of them conducted in the Southern European region and one conducted in the Northern European region

After one application at 25 g a.s./ha in the field, initial residues in fruit ranged between <0.01 mg/kg and 0.065 mg/kg and declined to <0.01 – 0.030 mg/kg, <0.01 – 0.028 mg/kg and <0.01 – 0.015 mg/kg 2-4, 6-8 and 13-14 days after application, respectively.

Under glasshouse conditions, initial residues between 0.016 mg/kg and 0.049 mg/kg were found after application of 40 g alpha-cypermethrin/ha. Residues declined to 0.011 – 0.028 mg/kg, <0.01 – 0.029 mg/kg and 0.011 – 0.033 mg/kg after 3, 7 and 14 days, respectively.

Conclusion:

After application of alpha-cypermethrin to sweet pepper plants according to the proposed GAP, determinable residues within a range below 0.1 mg/kg have to be expected in pepper fruit.

Residues found in sweet pepper fruit after treatment with alpha-cypermethrin according to the GAP for the glasshouse use show a tendency to higher values as compared to the open field situation. The residue levels determined range below 0.1 mg/kg.

2.7.2 Estimation of MRL, HR and STMR for pepper, sweet

For *sweet pepper*, the following residue studies were considered (BASF DocIDs): 2006/1026860, 2006/1036933 and 2007/1008497.

The following residue values (PHI=7±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Southern Europe (S-EU) [mg/kg]
2006/1026860 (open field)	<0.01 (2x), 0.015, 0.028
2007/1008497 (open field)	<0.01 (2x), 0.0170, 0.024
OECD-MRL-calculation (open field)	**<u>0.05</u> (n=8, STMR=0.013, HR=0.028)**
2006/1036933 (glasshouse)	0.016 (2x), 0.017, 0.018, 0.029, 0.033
OECD-MRL-calculation (glasshouse)	**<u>0.07</u> (n=6, STMR=0.018, HR=0.033)**

Guidelines:	EEC 91/414 Annex II (Part A Section 6), EEC 91/414 Annex III (Part A Section 8), EEC 7029/VI/95 rev. 5, EEC 7525/VI/95 rev. 7, EEC 1607/VI/97 rev. 2 10.06.1999
GLP	Yes

Executive Summary

During the growing season of 2008, a total of four trials with tomato was conducted in Germany, Northern France, Italy and Spain, to determine the magnitude and decline of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC). Therefore two solo formulations BAS 310 51 I (50 g/L BAS 310 I, ME) and BAS 310 40 I (100 g/L BAS 310 I, EC) were applied twice or once to the treated plot at a rate equivalent of 0.0150 kg a.s./ha or 0.0300 kg a.s./ha. In all trials the applications were made at crop stages BBCH 71 and 89.
For the analysis the tomato specimens were taken immediately after the last treatment (0 DALA) and at 2±1, 7±1 and 14 DALA. The tomato specimens were analysed for residues of BAS 310 I according to BASF Method No. 567/0, which has a limit of quantitation (LOQ) of 0.01 mg/kg. The analytical results obtained demonstrate that the treatment with one or two applications of BAS 310 51 I and BAS 310 40 I did not lead to significantly different residue results in the raw agricultural commodity at harvest.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 51 I (ME)
BAS 310 40 I (EC)
Lot/Batch #: 101156 BAS 310 51 I, 50 g/L alpha-cypermethrin
1209 BAS 310 40 I, 100 g/L alpha-cypermethrin
Purity:
CAS#: 67375-30-8 alpha-cypermethrin
Development code:
Spiking levels: 0.01-1.0 mg/kg

2. Test Commodity:

Crop: Tomato
Type: Fruiting vegetables
Variety: Vanessa, Topkapi, Asterix, Brillante
Botanical name: *Lycopersicon esculentum*
Crop parts(s) or processed
Commodity: Fruit
Sample size: 1.0-2.0 kg

B. STUDY DESIGN

1. Test procedure

During the growing season of 2008, a total of four trials with tomato were conducted in Germany, Northern France, Italy and Spain to determine the magnitude and decline of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC).
Each field trial consisted of three plots, one control plot (plot 1), one plot treated with BAS 310 51 I (plot 2) and another plot treated with BAS 310 40 I (plot 3).
In two of four trials (L080 173 and L080 174) both formulations (BAS 310 51 I, BAS 310 40 I) were applied twice at a rate equivalent to 0.015 kg alpha-cypermethrin/ha and for the others trials (L080175 and L080176) the application was made once at a rate equivalent to 0.0300 kg alpha-cypermethrin/ha. Both formulations were applied with the same GAP. The applications took place at BBCH 71-89 with an application rate of 400 L/ha. For the analysis the tomato specimens were taken immediately after the last treatment (0 DALA) and at 2±1, 7±1 and 14 DALA.

Table 2.8.1-1: Target application rates and timings for tomato

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2008	4	2	F	BAS 310 51 I (ME)	alpha-cypermethrin	0.0150	400	1st appl.: 72-76 BBCH 2nd appl.: 82-89 BBCH
		2	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0150	400	1st appl.: 72-76 BBCH 2nd appl.: 82-89 BBCH
		1	F	BAS 310 51 I (ME)	alpha-cypermethrin	0.0300	400	1st appl.: 71-85 BBCH
		1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0300	400	1st appl.: 71-85 BBCH

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin). The residues of alpha-cypermethrin in the tomato specimens were extracted from plant matrices using a mixture of methanol/water/hydrochloric acid. A liquid/liquid partition against cyclohexane was used for clean up. The final determination of alpha-cypermethrin was performed by LC-MS/MS. The limit of quantitation (LOQ) of the method is 0.01 mg/kg. Procedural recoveries averaged 99±9% for alpha-cypermethrin at fortification levels of 0.01 mg/kg and 1.0 mg/kg for each matrix in all specimens.

Table 2.8.1-2: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in tomato

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Fruit	0.01-1.0	9	99	9	9

II. RESULTS AND DISCUSSION

The residue levels of alpha-cypermethrin (BAS 310 I) in tomato specimens taken directly after the last application (0 DALA) and at 2±1 DALA of BAS 310 51 I ranged between <0.01-0.03 mg/kg in all trials. At 7±1 DALA and at 14 DALA, residues were <0.01-0.02 mg/kg.

Residues found in tomato specimens after the application of BAS 310 40 I lead to similar residue results of alpha-cypermethrin.

None of the analysed untreated specimens showed alpha-cypermethrin residues exceeding the respective method LOQ.

An overall summary of the residues is given in the table below.

Table 2.8.1-3: Summary of residues of BAS 310 I in tomato from trials according to critical GAP after application of BAS 310 51 I and BAS 310 40 I

Crop	Year	No. of Appl.	Application	DALA	BBCH	Residues Found (mg/kg)	
						Matrix	alpha-cypermethrin (BAS 310 I)

				7-8	86-89		0.01-0.02
				14	88-89		<0.01-0.02

DALA = days after last application
BBCH = growth stage at respective sampling

III. CONCLUSION

Directly after the last application of BAS 310 51 I and BAS 310 40 I, the residue of alpha-cypermethrin ranged between 0.01-0.03 mg/kg in tomato specimens. At 2±1 days, residues ranged between <0.01-0.03 mg/kg. At 7±1 days and later, residues found were <0.01-0.02 mg/kg.
The analytical results obtained demonstrate that the treatment with one or two applications of BAS 310 51 I and BAS 310 40 I did not lead to significantly different residue results in the raw agricultural commodity at harvest.

Diehl M (2007): Study on the residue behaviour of BAS 310 I in tomato after treatment with BAS 310 40 I under open field conditions in Southern and Northern Europe, 2006; BASF DocID 2007/1008494

Material and Methods:

A residue program in tomatoes was conducted in the years 2004, 2005 and 2006 in representative tomato growing areas in Belgium, Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain and the Netherlands under open field and glasshouse conditions.

During the 2005 growing season, eight trials were conducted in tomatoes under open field conditions, four of them in the Northern European region (in Belgium, France and Germany) and four in the Southern European region (in France, Italy and Spain).
Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L, BAS 310 40 I) was foliar applied to tomato plants in several variants. In four trials located in the Northern European region, the product was applied once at target rate of 12.5 g a.s./ha. This was compared to another variant in which two applications were made at the same target application rate. The last application took place at growth stages between 69 (9 or more inflorescences with open flowers) and 85 (50% of fruits show typical fully ripe colour).

At four other trials located in the Southern European region, a third variant was assayed in which BAS 310 40 I was applied once at a target rate of 25 g a.s./ha at growth stages between 81 (10% of fruits show typical fully ripe colour) and 89 (fully ripe). Tomato specimens were collected directly after the last application as well as 3, 7 and 14 days thereafter.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

A total of 8 residue trials were conducted during the 2006 growing season under open field conditions in Germany, France (Northern and Southern European region), Greece, Italy and Spain.
All trials were performed with an emusifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L, BAS 310 40 I).
In the trials performed in the Northern European region (4 sites) the product was sprayed on separate plots of tomato plants at two different rates: variant 1 received one treatment at a target rate of 12.5 g a.s./ha, while in variant 2, two treatments at 12. 5 g a.s./ha were applied. The last application took place at growth stages between 79 (9th fruit cluster: first fruit has reached typical size) and 84 (40% of fruits show typical fully ripe colour). Samples of tomatoes were collected 0, 3, 7 and 14 days after the last application.
In the trials performed in the Southern European region (4 sites) the product was applied once at a target rate of 25 g a.s./ha. The application took place at growth stages between 73 (3rd fruit cluster: first fruit has reached typical size) and 88 (80% of fruits show typical fully ripe colour). Samples of tomatoes were collected 0, 2-4, 6-8 and 14 days after application.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, four bridging trials were conducted in France (Northern and Southern European region), Germany and Spain under open field conditions to compare the residue behaviour after application of two different formulations of alpha-cypermethrin.
An emulsifiable concentrate formulation (EC 100 g a.s./L, BAS 310 40 I) and a wettable granule formulation (WG 150 g/kg, BAS 310 08 I) were foliar applied to separate plots of tomato plants, each one at the following rates: One treatment at 12.5 g a.s./ha (variant 1), two treatments at 12.5 g a.s./ha (variant 2), or one treatment at 25 g a.s./ha (variant 3). Variants 1 and 2 were included in the trials located in the Northern European region and variant 3 was included in the trials located in the Southern European region. Samples of tomato fruit were collected immediately after the last application as well as 2-4, 6-8, and 14 days afterwards.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2004 growing season, eight residue trials were conducted in tomatoes grown in glasshouses.
Alpha-cypermethrin, formulated as a soluble concentrate (SC 100 g a.s./L, BAS 310 41 I) was foliar applied to tomatoes on two different plots. In one variant, one application was made at a target rate of 15 g a.s./ha. This was compared to another variant in which two applications were made at the same target application rate. The last application took place at growth stages between 76 (6th fruit cluster: first fruit has reached typical size) and 85 (50% of fruits show typical fully ripe colour). Tomato fruit specimens were collected directly after the last application from each plot at all locations, and at 2-4, 6-7 and 13-14 days after the last application. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

Eight glasshouse trials were conducted during the 2005 growing season in Belgium, France (Northern and Southern European region), Germany, Greece, Italy and Spain.
Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L, BAS 310 40 I) was foliar applied to tomato once at a target rate of 40 g a.s./ha at growth stages between 71 (first fruit cluster: first fruit has reached typical size) and 88 (80% of fruits show typical fully ripe colour).
Tomato samples were collected 0, 2-3, 7 and 14-15 days after application.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarized in Table 2.8.1-6 and Table 2.8.1-7.

Table 2.8.1-6: Residues in tomatoes – open field trials

GAP for EU-N is 1-2 applications with 15 g a.s./ha at infestation as an overall spray, PHI = 3 days (outdoor) GAP for EU-S is 1 application with 30 g a.s./ha at infestation as an overall spray, PHI = 2 days (outdoor) or Glasshouse GAP is 1 application with 30 g a.s./ha at infestation as an overall spray, PHI = 2 days , or 1 application with 50 g a.s./ha at infestation as an overall spray, PHI = 7 days

_ underlined values were used for MRL calculation

Findings:

The residue data in tomatoes presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to conditions in the Northern and Southern European region and to glasshouse conditions.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 3 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 2 days
- glasshouse GAP is a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 2 days or a single application with 50 g a.s./ha with a PHI of 7 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions-10 trials including both variants on different plots, 2 of them bridging trials with two different formulations, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions-10 trials, 2 of them bridging trials with two different formulations, all conducted in the Southern European region
- one or two treatments at a target rate of 15 g a.s./ha under glasshouse conditions-8 trials including both variants on different plots, 4 conducted in the Northern European region and 4 conducted in the Southern European region
- one treatment at target rate of 40 g a.s./ha under glasshouse conditions-8 trials, 4 conducted in the Northern European region and 4 conducted in the Southern European region

In the open field trials, consistently very low residues were found.

After one application at a target rate of 12.5 g a.s./ha, no residues above the limit of quantitation of the analytical method were found in any treated tomato fruit sample, regardless of sampling interval (all <0.01 mg/kg).

After two applications at a target rate of 12.5 g a.s./ha, initial residues in tomato fruit samples from three out of twelve plots ranged between 0.011-0.013 mg/kg. In all other samples taken immediately after the last application residues were below the LOQ (<0.01 mg/kg). A residue at the LOQ (0.01 mg/kg) was found in one trial three days after the last application. Besides this finding, residues in all other treated samples were below the LOQ (<0.01 mg/kg).

After one application at a target rate of 25 g a.s./ha, initial residues tomato fruit ranged between <0.01-0.021 mg/kg. Residues between 0.013-0.021 mg/kg were found in three trials three days after application, while in all other trials the residues were below the LOQ (<0.01 mg/kg) at this sampling point. Seven days after application, a residue of 0.013 mg/kg was determined in two trials, while all other treated samples taken at the same time as well as all treated samples taken 14 days after application did not show residues above the LOQ (all <0.01 mg/kg).

The residue situation in the glasshouse trials was as follows:

After one application at a target rate of 15 g a.s./ha under glasshouse conditions, residues in tomato fruit were below the method LOQ (<0.01 mg/kg) in all trials at all sampling times with only one exception (trial ALB/06/04): 7 days after application, a residue of 0.019 mg/kg was found in fruit, while all other samples from the same plot taken earlier or later did not show residues above the LOQ (all <0.01 mg/kg).

After two applications at a target rate of 15 g a.s./ha under glasshouse conditions, in four out of eight trials no determinable residues were found at any sampling interval (all <0.01 mg/kg). In the other four trials, initial residues in tomato fruit ranged between 0.011-0.019 mg/kg and declined to <0.01-0.018 mg/kg, <0.01-0.013 mg/kg and <0.01-0.015 mg/kg after 2-4, 6-7 and 13-14 days, respectively.

After one application at a target rate of 40 g a.s./ha under glasshouse conditions, initial residues in tomato fruit ranged between <0.01-0.030 mg/kg.
Residue levels found at later sampling points were <0.01-0.037 mg/kg, <0.01-0.024 mg/kg and <0.01-0.032 mg/kg after 3, 7 and 14 days, respectively.

Conclusion:

A residue program in tomatoes was conducted in the years 2004, 2005 and 2006 in representative tomato growing areas in Belgium, Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain and the Netherlands under open field and glasshouse conditions.

Treatment of tomato plants with alpha-cypermethrin under open field conditions according to the proposed GAP leads to a favourable residue situation. Residue levels in tomato fruit are very low with the majority of values within a range below the limit of quantitation of the analytical method.
In 10 trials (including 12 treated plots) supporting the proposed field GAP for the Northern European region, a residue at the LOQ (0.01 mg/kg) was found in one trial three days after the last application. Besides this finding, residues in all other treated samples were below the LOQ (<0.01 mg/kg) at the target PHI of 3±1 days.
In 10 trials (including 12 treated plots) supporting the proposed field GAP for the Southern European region, residues between 0.013-0.021 mg/kg were found in three trials at the target PHI of 3±1 days, while in all other trials the residues were below the LOQ (<0.01 mg/kg) at this sampling point.

Results showed that residues after BAS 10 40 I and BAS 310 08 I treatment were comparable.

Treatment of tomato plants with alpha-cypermethrin under glasshouse conditions represents a worst case situation with regard to residues with a tendency to higher residue levels at application rates that are comparable to the open field GAP.
In 8 trials supporting the proposed glasshouse GAP, residues ranged between <0.01-0.037 mg/kg at the target PHI of 3 days and between <0.01-0.024 mg/kg at the target PHI of 7 days.

2.8.2 Processing study in tomato

Report:

Schulz H. 2006a
Study on the Residue Behaviour of Alpha-Cypermethrin in Tomato and Processed Products after Treatment of BAS 310 41 I under Greenhouse Conditions in Germany and The Netherlands, 2004
2006/1021295

Guidelines: EEC 91/414 Annex II (Part A Section 6),EEC 91/414 Annex III (Part A Section 8),EEC 1607/VI/97 rev. 2 10.06.1999,EEC 7029/VI/95 rev. 5,EEC 7525/VI/95 rev. 7,EEC 7035/VI/95 rev. 5

GLP: yes
(certified by Hessisches Ministerium für Umwelt, Laendlichen Raum und Verbraucherschutz)

Material and methods:

During the 2004 growing season, four greenhouse trials in tomato were conducted in Germany (Brandenburg; ACK/09/04 and ACK/10/04) and the Netherlands (Limburg; AGR/12/04 and AGR/13/04) in order to determine the magnitude and distribution of alpha-cypermethrin residues in a number of intermediate and end products after processing.

Two of the trials consisted of two plots, one untreated and one treated (ACK/09/04 and AGR/12/04); the other two (ACK/10/04 and AGR/13/04) consisted of one treated plot each.

Tomato plants (varieties: Clothilde in the German trials and Cedrico in the Dutch trials) were foliar sprayed twice with a soluble concentrate formulation of alpha-cypermethrin (SC 100 g/L, code: BAS 310 41 I) at a rate of 75 g a.s./ha. Actual rates were within +/10 % of the nominal rate. This exaggerated treatment rate was used in an effort to generate finite alpha-cypermethrin residues in tomato so that the distribution of the residue in the processed fractions could be better quantified.

The applications were made 14(±1) and 7(±1) days before harvest. The growth stage at the last application was BBCH 85 in all trials (50% of fruits show typical fully ripe colour). The spray volume used was 400 I/ha. Tomato fruit samples were collected immediately after the second application and 7 days thererafter.
Field samples for residue analysis from all trials were frozen within 24 hours of sampling and remained frozen (including during transportation) during analysis.

18 - 23 kg of tomatoes were picked for processing at 7 days after application from every trial.
The processing phase was conducted at NIG GmbH Nahrungs-Ingenieurtechnik GmbH, Wasserkunststr. 26, O-39124 Magdeburg, Germany.

The following specimens resulted from the processing:
- washed tomatoes
- wash water
- peeled tomatoes
- peel
- dipping water
- canned tomatoes
- vegetable stock
- tomato juice
- remainder of the straining process
- tomato puree
- tomato paste
- condensed water

These processing products fulfil the requirements for a balance study.

The analytical part of the study was performed at the Agricultural Research Center of BASF in Limburgerhof, Germany.
The specimens were analysed for residues of alpha-cypermethrin by means of HPLC-MS/MS according to BASF method N° 567/0. This method quantifies the residues in tomatoes and processed products with a limit of quantification (LOQ) of 0.01 mg/kg.
Method performance was checked by determining the procedural recoveries in tomato RAC and processed fractions.
At fortification levels between 0.01 and 1.0 mg/kg, the recovery rates averaged at 95% with a standard deviation of 8.4 and a coefficient of variation of 8.9%.

Findings:

No residues of alpha-cypermethrin at or above the validated method LOQ (0.01 mg/kg) were detected in the untreated RAC species.

Directly after the last application, alpha-cypermethrin was found between 0.07 and 0.10 mg/kg in tomato fruit. After 7 days, the residues had declined to levels between 0.04 and 0.09 mg/kg.

No detectable residues were found above the validated method LOQ (0.01 mg/kg) in any untreated tomato processed fractions (washed tomatoes, wash water, peeled tomato, peel, dipping water, canned tomato, vegetable stock, tomato juice, remainder of straining, tomato puree, tomato paste and condensed water).
After washing, the treated tomatoes still showed residues between 0.04 and 0.07 mg/kg, in the wash water were no residues above the LOQ. After peeling; residues of alpha-cypermethrin were only found on the peel (0.39 to 1.58 mg/kg), the peeled fruits as well as the canned tomatoes made thereof were free of alpha-cypermethrin (< 0.01).
Tomato juice contained alpha-cypermethrin residues between 0.01 and 0.02 mg/kg. In the concentrated fractions puree and paste higher levels (0.02-0.04 mg/kg and 0.04-0.11 mg/kg) were found according to the degree of concentration.

The total alpha-cypermethrin residues in tomato and processed products as well as the corresponding transfer factors were as follows, whereby the transfer factors in the tomato fruit (RAC) were set as 1:

Table 2.8.2-1: Summary of alpha-cypermethrin residues in tomatoes and transfer factors - DocID 2006/1021295

Specimen	DALA [1)]	Total Alpha-cypermethrin Residues mg/kg	Transfer Factors Trial No.			
			ACK/09/04	ACK/10/04	AGR/12/04	AGR/13/04

1) days after last application

Compared to the alpha-cypermethrin residues in tomato fruit taken at 7 days after last application, no remarkable residue changes occurred in the washed tomatoes. In the peeled tomatoes, no residues above the LOQ were found, whereas the highest residue concentration was obtained in the peel, indicating that alpha-cypermethrin was concentrated on the tomato surface. Transfer factors between 3.1 and 8.3 were obtained in the remainder of the straining process, which contained a high content of peel. In tomato juice and in tomato puree, the alpha-cypermethrin residues were lower than those of the RAC specimens. A slight enrichment was found in tomato paste where the transfer factors were between 1.0 and 1.8. No residues above the limit of quantification were obtained in the aqueous specimens wash water, dipping water, vegetable stock and condensed water.

Tomato processing summary – preparation of canned tomatoes, sterilized juice, tomato puree and tomato paste:

Tomatoes suitable for processing were sorted out by hand. The tomatoes were washed in water (18 °C, 9 washing batches, 3 min duration each). Peeling was achieved by dipping in hot (90 °C) and cold water. The tomatoes were then canned and sterilized at 120 °C for 18 min.
For preparation of juice, the tomatoes were strained (3 runs, heating up to 85 °C, duration of straining for each run approx. 1 min). The juice was sterilized at 120 °C for 18 min.
Paste and puree were prepared by concentration of juice through evaporation under reduced pressure.

Yield (%)	88.0	86.9	98.3	99.6	88.5	99.6

1) Low yield, because one out of three glasses was broken 2): Because of an error of the autoclav, the second specimen batch must be discarded. Yield was incalculable

Conclusion:

The residue data obtained in this processing study clearly demonstrate that alpha-cypermethrin residues are reduced compared to the levels in the raw agricultural commodity during processing to peeled and canned tomatoes, juice and pureé. This is due to the fact that alpha-cypermethrin residues are located on the peel and are retained in the peel fraction during processing.
A slight enrichment of alpha-cypermethrin residues was only found in tomato purée which can be attributed to the high concentration of the juice used as starting material.

2.8.3 Estimation of MRL, HR and STMR for tomato

For *tomato*, the following residue studies were considered (BASF DocIDs): 2007/1008488, 2007/1008494, 2007/1007937, 2009/1090704 and 2007/1007937.

The following residue values (PHI=3±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (S-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2007/1008488 (open field)	<0.01 (4x)	<0.01 (2x), 0.013, 0.021
