2.9 Cucumber / courgette

Besidues the new studies presented in Section M-CA 6.3, no additional residue data were considered for cucumber / courgette.

2.10 Melon

Residue data from supervised trials in melons were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.10-1: Number of residue trials conducted per geographical region and vegetation period

Material and Methods:

In the years 2004-2006 a residue program in melons was conducted in Belgium, Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain and the Netherlands under open field and glasshouse conditions.

During the 2005 growing season, four trials were conducted in melon under open field conditions in France (Southern European region), Italy and Spain. Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to melon plants once at a target rate of 25 g a.s./ha. The growth stage of the plants at application was between 72 (2nd fruit on main stem has reached typical size and form) and 85 (50% of fruits show typical fully ripe colour). Melon fruit specimens were collected directly after the last application as well as approximately 3, 7 and 14 days thereafter.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, four trials were conducted in melon under open field conditions in France (Southern European region), Greece, Italy and Spain. Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to melon plants once at target rate of 25 g a.s./ha. The growth stage of the plants at application was between 71 (first fruit on main stem has reached typical size and form) and 88 (80% of fruits show typical fully ripe colour). Melon fruit specimens were collected directly after the last application as well as 2-3, 7 and 14 days thereafter.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2004 growing season, six trials were conducted in Denmark, France (Southern European region), Italy, Spain and the Netherlands in melons grown in glasshouses. A soluble concentrate formulation of alpha-cypermethrin (SC 100 g a.s./L; BAS 310 41 I) was foliar applied to melon plants on two different plots. In one variant, one application was made at a rate of 15 g a.s./ha. This was compared to another variant in which two applications were made at the same application rate. The growth stage of the plants at application was between 77 (7th fruit on main stem has reached typical size and form) and 87 (70% of fruits show typical fully ripe colour). Melon specimens were collected directly after the last application as well as about 2-4, 7 and 13-15 days thereafter.
The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

Eight glasshouse trials were performed in the year 2005 in Belgium, Denmark, France (Southern European region), Germany, Greece, Italy and Spain to determine the magnitude of the residue after application of a 100 g a.s./L emulsifiable concentrate formulation of alpha-cypermethrin (EC; BAS 310 40 I). The product was foliar applied once at a rate of 40 g a.s./ha. The growth stage of the plants at application was between 71 (first fruit on main stem has reached typical size and form) and 87 (70% of fruits show typical fully ripe colour). Samples of melon fruit were collected 0, 2-3, 7-8 and 13-14 days after application. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.10.1-1 and Table 2.10.1-2

Table 2.10.1-1: Residues in melons – open field trials

Findings:

The residue studies in melons presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to open field conditions in the Southern European region and to glasshouse conditions.
The proposed GAP is

- for the Northern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days under open field conditions
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 2 days under open field conditions
- glasshouse GAP is a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 2 days or a single application with 50 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days

The following residue studies were presented:

- one treatment at a target rate of 25 g a.s./ha under open field conditions-8 trials conducted in the Southern European region
- one or two treatments at a target rate of 15 g a.s./ha under glasshouse conditions-6 trials including both variants, 2 of them conducted in the Northern European region and 4 of them conducted in the Southern European region
- one treatment at a target rate of 40 g a.s./ha under glasshouse conditions-8 trials, 3 of them conducted in the Northern European region and 5 of them conducted in the Southern European region

After one application at 25 g a.s./ha under field conditions, initial residues of 0.014 mg/kg were found in two out of eight trials. Residues of 0.014 mg/kg were found in one treated sample 3 days after application. No residues above the limit of quantitation of the analytical method (LOQ; 0.01 mg/kg) were found in any other treated sample from these eight trials, regardless of sampling interval (all <0.01 mg/kg).

After one application of alpha-cypermethrin at a rate of 15 g a.s./ha under glasshouse conditions, residues were below the LOQ (<0.01 mg/kg) in all treated melon fruit samples in five out of six trials. Determinable residues were found only in three samples from trial AGR/11/04; these samples were collected at 0-, 7- and 14-days after application, and contained residues of 0.013, 0.010, and 0.011 mg/kg, respectively.
Immediately after the last of two applications at a rate of 15 g a.s./ha under glasshouse conditions, residues in melon fruit ranged from below the LOQ (<0.01 mg/kg) to 0.014 mg/kg, and were generally below or near the LOQ for the remainder of the study. Residues were between <0.01 mg/kg (LOQ) and 0.013 mg/kg in melon samples collected at the end of the study, 13-15 days after the last application.

After one treatment with 40 g alpha-cypermethrin/ha under glasshouse conditions, initial residues ranged between <0.01 mg/kg and 0.074 mg/kg. Residues declined to <0.01-0.070 mg/kg, <0.01-0.048 mg/kg and <0.01-0.045 mg/kg at 2-3, 7-8 and 13-14 days after application, respectively.

Conclusion:

In the years 2004-2006 a residue program in melons was conducted in Belgium, Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain and the Netherlands under open field and glasshouse conditions.

The trial data demonstrate that residues in melon fruit arising from treatment with alpha-cypermethrin according to GAP are very low under field conditions.
In 8 trials supporting the proposed field GAP for the Southern European region, residues of 0.014 mg/kg were found in one treated sample 3 days after application. No residues above the limit of quantitation of the analytical method (LOQ; 0.01 mg/kg) were found in any other treated sample at the target PHI of 3±1 days.

As expected, there is a tendency to higher residue values under glasshouse conditions as compared to the open field situation.

In 8 trials supporting the proposed glasshouse GAP, residues ranged between <0.01-0.07 mg/kg at the target PHI of 3±1 days and between <0.01-0.048 mg/kg at the target PHI of 7±1 days.

2.10.2 Processing study in melon

Report:	Schroth E. 2006a Study on the residue behavior of Alpha-cypermethrin on melons after application of BAS 310 41 I under greenhouse conditions in Spain, 2004 2006/1038660
Guidelines:	91/414/EEC, 1607VI/97 rev. 2, 10.6.1999 EC 7029/VI/95 rev. 5, 22.7.1997 EC 7525/VI/95 rev. 7, 12.6.2001
GLP:	yes (certified by: Testing facility: not reported, Analytical lab.: Landesamt für Umweltschutz und Gewerbeaufsicht, Main, Germany)

Material and methods:

During the 2004 growing season, 4 greenhouse trials were conducted in different representative melon growing areas in Spain to determine the distribution of residue levels of alpha-cypermethrin (BAS 310 I) between peel and pulp of melon fruit. Two trials (ALO/01/04 and ALO/02/04) were conducted in climbing melons (variety Ciclo), and two (ALO/03/04 and ALO/04/04) were conducted in ground melons (varieties Maxdimon and Piñonet).

A soluble concentrate formulation of alpha-cypermethrin (100 g a.s./L; BAS 310 41 I) was foliar applied twice with a target application rate of 75 g a.s./ha. Actual rates were within +/10 % of the nominal rate. This exaggerated treatment rate was used in an effort to generate finite alpha-cypermethrin residues in melons so that the distribution of the residue between peel and pulp could be better quantified.

The applications were made 14(±1) and 7(±1) days before harvest. The growth stage at the last application was BBCH 81 (10% of fruits show typical fully ripe colour) for trials ALO/01/04 and ALO/02/04; and BBCH 79 (9 or more fruits on main stem have reached typical size and form) for trials ALO/03/04 and ALO/04/04. The spray volume used was 400 I/ha.

Specimens of fruits were collected at the day of the last application as well as 6 (ALO/01/04 and ALO/02/04) or 7 days (ALO/03/04 and ALO/04/04) thereafter. Specimens of peel and pulp were collected 6-7 days after the last application. The samples from the four trials were frozen within 24 hours of sampling remained frozen at or below -18°C, including during transportation, until analysis.
The analytical part of the study was performed at the Agricultural Research Center of BASF in Limburgerhof, Germany.

The specimens (RAC) as well as the processed commodity samples were analysed for alpha-cypermethrin by means of HPLC-MS/MS according to the BASF method no. 567/0. The limit of quantification (LOQ) of the method was 0.01 mg/kg for all sample materials analysed.
Method performance was checked by determining the procedural recoveries in melon matrices.
At fortification levels between 0.01 and 1.0 mg/kg, the recovery rates averaged at 76% with a standard deviation of 3.9 and a coefficient of variation of 5.1%.

Findings:

No detectable alpha-cypermethrin residues above the validated method LOQ (0.01 mg/kg) were found in any of the untreated melon fruit specimens or processed fractions (peel and pulp) obtained from untreated melon fruit specimens.

No residues above the LOQ (0.01 mg/kg) were found in any of the treated samples from trial ALO/03/04 or in the processed fractions (peel and pulp) obtained from treated melon fruit.

In the remaining three trials, initial residues ranged between 0.02 – 0.03 mg/kg. On day 6-7 after the last application, residues in melon fruit ranged between 0.01 – 0.02 mg/kg. No detectable residues were found in pulp specimens obtained from treated melon fruit (all <0.01 mg/kg), while the peel fractions showed residues between 0.01-0.07 mg/kg.

The residue levels in the individual fractions are summarized below:

Table 2.10.2-1: Residue distribution between peel and pulp of melons – DocID 2006/8038660

Trial No:	Alpha-cypermethrin residue (mg/kg)			
	Melon fruit	Melon fruit	Peel	Pulp
	0 DALA [1)]	6-7 DALA	6-7 DALA	6-7 DALA
ALO/0104	0.03	0.02	0.07	<0.01
ALO/0204	0.02	0.02	0.05	<0.01
ALO/03/04	<0.01	<0.01	<0.01	<0.01
ALO/0404	0.02	0.01	0.01	<0.01

1) days after last application

Conclusion:

The data from this processing study clearly demonstrate that there are no detectable residues of alpha-cypermethrin in the pulp (edible part) of melons. The residue is located exclusively on the peel.

2.10.3 Estimation of MRL, HR and STMR for melon

For *melon*, the following residue studies were considered (BASF DocIDs): 2006/1024607, 2007/1011007, 2007/1007940 and 2006/1037507.

The following residue values (PHI=3±1 days for the open field trials and PHI=7±1for the glassnouse trials) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1024607 2007/1011007 (field)	-	<0.01 (4x)
2007/1007940 (field)	-	<0.01 (3x), 0.014
OECD-MRL-calculation	-	**<u>0.02</u> (n=8, STMR=0.01, HR=0.014)**
2006/1037507 (glasshouse)		<0.01 (5x), 0.022, 0.029, 0.048
OECD-MRL-calculation		**<u>0.08</u> (n=8, STMR=0.01, HR=0.048)**

_ underlined values were used for risk assessment purposes

<u>Pumpkin</u>

As the critical GAPs for melons and pumpkins are identical, according to European Community Guideline 7525/VI/95 rev. 9 dated March 2011 extrapolation from melons to pumpkins is adequate.

2.11 Broccoli

Residue data from supervised trials in broccoli were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.11-1: Number of residue trials conducted per geographical region and vegetation period

Crop	Vegetation Period	Number of Trials					Report-No.

Diehl M (2007): Study on the Residue Behaviour of BAS 310 I in Broccoli after Treatment with BAS 310 40 I under open field Conditions in Southern and Northern Europe, 2006; BASF DocID 2007/1013274

Material and Methods:

In the years 2005 and 2006 a residue program on broccoli was conducted in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain, The Netherlands and the United Kingdom under field conditions.

During the 2005 growing season, six field trials were conducted in different representative broccoli growing areas in the United Kingdom, Germany, the Netherlands, France and Italy.

In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to broccoli plants either once or twice to separate plots at a target rate of 12.5 g a.s./ha.
The growth stage of the plants at application was between 45 (50% of the expected head diameter reached) and 55 (first individual flowers visible (still closed)). Specimens of broccoli inflorescences were collected immediately after the last application from each plot, as well as 3, 7 and 14 days thereafter.

In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to broccoli plants once at a target rate of 25 g a.s./ha.
The growth stage of the plants at application was between 46 and 47 (60 - 70% of the expected head diameter reached). Specimens of broccoli inflorescence were collected immediately after the last application, as well as 3, 7 and 14 days thereafter.
Specimens were analysed using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantification of 0.01 mg/kg in all sample materials.

During the 2006 growing season, six field trials were conducted in different representative broccoli growing areas in Denmark, France (Northern European region), Germany, Greece, Spain and the United Kingdom.

In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to broccoli plants either once or twice to separate plots at a target rate of 12.5 g a.s./ha.
The growth stage of the plants at application was between 43 (30% of the expected head diameter reached) and 49 (typical size and form reached; head tightly closed).
Specimens of broccoli inflorescence were collected immediately after the last application from each plot, as well as 3, 7 and 14 days thereafter.

In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to broccoli plants once at a target rate of 25 g a.s./ha.
The growth stage of the plants at application was between 47 (70% of the expected head diameter reached) and 49 (typical size and form reached; head tightly closed). Specimens of broccoli inflorescence were collected immediately after the last application, as well as 2-4, 6-7 and 14 days thereafter.
Specimens were analysed using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantification of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarized in Table 2.11.1-1.

_ underlined values were used for MRL calculation

Findings:
The residue studies in broccoli presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 2 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions – 8 trials including both variants; all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions – 4 trials conducted in the Southern European region

After one application at 12.5 g a.s./ha, initial residues in broccoli inflorescences ranged between 0.032 mg/kg and 0.163 mg/kg. Residues declined to levels between <0.01 – 0.048 mg/kg, and <0.01 – 0.025 mg/kg at 2-3 and 6-7 days after application. At the last sampling, 13-15 days after application, only in one single trial a residue of 0.017 mg/kg was found. All other treated samples did not show determinable residues (all <0.01 mg/kg).

After two applications at 12.5 g a.s./ha, initial residues in broccoli inflorescences ranged between 0.259 mg/kg and 0.048 mg/kg. Residues declined to levels between <0.01 – 0.039 mg/kg and <0.01 – 0.029 mg/kg at 2-3 and 6-7 days after the last application. At the last sampling, 13-15 days after application, only in one single trial a residue of 0.018 mg/kg was found. All other treated samples did not show determinable residues (all <0.01 mg/kg).

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in broccoli ranged between 0.050 mg/kg and 0.070 mg/kg. Residues declined to levels between 0.026 – 0.047 mg/kg, 0.013 – 0.027 mg/kg and <0.01 – 0.011 mg/kg at 3-4, 7 and 13-14 days after application.

Conclusion:

In 8 trials supporting the GAP for the Northern European region, residues in broccoli inflorescences ranged between <0.01 – 0.029 mg/kg at the target PHI of 7 (± 1) days.
In 4 trials supporting the GAP for the Southern European region, residues in broccoli inflorescences ranged between 0.026 – 0.047 mg/kg at the target PHI of 3 (± 1) days.

2.11.2 Estimation of MRL, HR and STMR for broccoli

For *broccoli*, the following residue studies were considered (BASF DocIDs): 2006/1026863 and 2007/1013274.

The following residue values (EU-N: PHI=7±1 days / EU-S: 3±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026863 (open field)	<0.01 (2x), 0.015, 0.018	0.028, 0.047
2007/1013274 (open field)	0.011, 0.017, 0.018, 0.029	0.026, 0.032
OECD-MRL-calculation (open field)	**0.05 (n=8, STMR=0.016, HR=0.029)**	**<u>0.1</u> (n=4, STMR=0.030, HR=0.047)**

_ underlined values were used for risk assessment purposes

2.12 Cauliflower

Residue data from supervised trials in cauliflower were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.12-1: Number of residue trials conducted per geographical region and vegetation period

Diehl M (2007): Study on the residue behaviour of BAS 310 I in cauliflower after treatment with BAS 310 40 I under open field conditions in Southern and Northern Europe, 2006; BASF DocID 2007/1008495

Material and Methods:

In the years 2005 and 2006 a residue program on cauliflower was conducted in the field in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom.

A total of six residue trials was conducted during the growing season 2005 in France (Northern and Southern European region), Germany, Italy, the Netherlands and the United Kingdom.
In four of these trials located in the Northern European region, separate plots of cauliflower plants received either one or two treatments with a 100 g a.s./L emulsifiable concentrate formulation of alpha-cypermethrin (EC; BAS 310 40 I) at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last treatment was between 41 (cauliflower heads begin to form; width of growing tip > 1 cm) and 47 (70% of the expected head diameter reached). Samples of cauliflower heads were collected immediately after application as well as approximately 3, 7 and 14 days after the last application.
In two trials located in the Southern European region, cauliflower plants received a single treatment with a 100 g a.s./L emulsifiable concentrate formulation of alpha-cypermethrin (EC; BAS 310 40 I) at a target rate of 25 g a.s./ha. The growth stage of the plants at the last treatment was between 43 (30% of the expected head diameter reached) and 47 (70% of the expected head diameter reached). Samples of cauliflower heads were collected immediately after application as well as 3, 7 and 14 days after the last application.
Residue analysis was performed according to BASF analytical method No. 567/0, which determines total cypermethrin residues by means of HPLC-MS/MS with a LOQ of 0.01 mg/kg.

A total of six residue trials was conducted during the growing season 2006 in Denmark, France (Northern European region), Greece, Spain, the Netherlands and the United Kingdom.
In four of these trials located in the Northern European region, separate plots of cauliflower plants received either one or two treatments with a 100 g a.s./L emulsifiable concentrate formulation of alpha-cypermethrin (EC; BAS 310 40 I) at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last treatment was between 42 and 47 (70% of the expected head diameter reached). Samples of cauliflower heads were collected immediately after application as well as 3, 6-8 and 13-14 days after the last application.

In two trials located in the Southern European region, cauliflower plants received a single treatment with a 100 g a.s./L emulsifiable concentrate formulation of alpha-cypermethrin (EC; BAS 310 40 I) at a target rate of 25 g a.s./ha. The growth stage of the plants at the last treatment was between 42 and 48 (80% of the expected head diameter reached). Samples of cauliflower heads were collected immediately after application as well as 3-4, 7 and 14 days after the last application.
Residue analysis was performed according to BASF analytical method No. 567/0, which determines total cypermethrin residues by means of HPLC-MS/MS with a LOQ of 0.01 mg/kg.

During the 2006 growing season, four bridging trials were conducted in France (Southern European region), Germany, Italy and the United Kingdom under open field conditions to compare the residue behaviour after application of two different formulations of alpha-cypermethrin.
An emulsifiable concentrate formulation (EC 100 g a.s./L, BAS 310 40 I) and a wettable granule formulation (WG 150 g/kg, BAS 310 08 I) were foliar applied to separate plots of cauliflower plants, each one at the following rates: One treatment at 12.5 g a.s./ha (variant 1), two treatments at 12.5 g a.s./ha (variant 2), or one treatment at 25 g a.s./ha (variant 3). Variants 1 and 2 were included in the trials located in the Northern European region and variant 3 was included in the trials located in the Southern European region.
At the last application, the growth stages of the plants were between 43 (30% of the expected head diameter reached) and 45 (50% of the expected head diameter reached) in the Northern European trials and at stage 45 in the Southern European trials. Samples of cauliflower heads were collected immediately after the last application as well as 2-4, 6-8, and 13-14 days afterwards. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.12.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in cauliflower presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 2 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions-10 trials including both variants in different plots, 2 of them bridging trials with two different formulations, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions-6 trials, 2 of them bridging trials with two different formulations, all conducted in the Southern European region

After one application at 12.5 g a.s./ha, initial residues of alpha-cypermethrin in cauliflower inflorescences ranged between <0.01 mg/kg and 0.123 mg/kg. Residues declined to levels between <0.01-0.042 mg/kg and <0.01-0.053 mg/kg at 3 and 7 days after application. At the last sampling date, 13-14 days after application, determinable residues at the limit of quantitation of the analytical method (LOQ: 0.01 mg/kg) were found only in one sample out of ten treated plots (0.011 mg/kg), while samples from the other nine plots showed residues below the LOQ (all <0.01 mg/kg).

After two applications at 12.5 g a.s./ha, initial residues in cauliflower inflorescences ranged between <0.01 mg/kg and 0.201 mg/kg. Residues declined to levels between <0.01-0.075 mg/kg and <0.01-0.085 mg/kg and at 2-4 and 6-8 days after the last application. At the last sampling date, 13-14 days after the last application, determinable residues were found only in one sample out of ten treated plots (0.027 mg/kg), while samples from the other nine plots showed residues below the limit of quantitation of the analytical method (LOQ; <0.01 mg/kg).
The residue levels found in one of the trials performed in the Northern European region exceeded by far those of the other trials conducted under comparable conditions (trial AF/8813/BA/3). This situation was found in both application variants.

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in cauliflower inflorescences ranged between <0.01 mg/kg and 0.16 mg/kg. Residues declined to levels between <0.01-0.083 mg/kg at 2-4 days after application. After 7-8 days, determinable residues of alpha-cypermethrin were found only in one treated sample (trial AF/10502/BA/3; 0.014 mg/kg), while all other treated samples showed residues below the LOQ at this sampling point (all <0.01 mg/kg). At the last sampling, 13-14 days after application, residues were below the LOQ in all treated samples (all <0.01 mg/kg).

Conclusion:

In the years 2005 and 2006 a residue program on cauliflower was conducted in the field in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom.
In 10 trials (12 plots) supporting the GAP for the Northern European region, residues ranged between <0.01-0.085 mg/kg at the target PHI of 7±1 days.
In 6 trials (8 plots) supporting the GAP for the Southern European region, residues ranged between <0.01-0.083 mg/kg at the target PHI of 3±1 days.

2.12.2 Estimation of MRL, HR and STMR for cauliflower

For *cauliflower*, the following residue studies were considered (BASF DocIDs): 2006/1026864, 2007/1008495 and 2007/1007936.

The following residue values (PHI=7±1 days for EU-N and PHI = 7±1 days for EU-S) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026864 (field)	<0.01 (3x), 0.085	<0.01 (2x)
2007/1008495 (field)	<0.01 (2x), 0.010, 0,011	<0.01 (2x)
2007/1007936 (field)	<0.01 (2x)	<0.01, 0.083
OECD-MRL-calculation	**0.15 (n=10, STMR=0.01, HR=0.085)**	**0.15 (n=6, STMR=0.01, HR=0.083)**

_ underlined values were used for risk assessment purposes

2.13 Brussels sprouts

Residue data from supervised trials in brussels sprouts were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

North L (2007): Study on the residue behaviour of alpha-cypermethrin in Brussels Sprout after treatment with BAS 310 40 I under field conditions in Northern and Southern Europe during 2006; BASF DocID 2007/1007943

Material and Methods:

In the years 2005 and 2006 a residue program on brussels sprouts was conducted in Belgium, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom under field conditions.

Eight trials were conducted in the Northern European region in order to determine the magnitude of the residue after application of a 100 g a.s./L alpha-cypermethrin emulsifiable concentrate formulation (EC 100 g/L; BAS 310 40 I). Separate plots of brussels sprouts were foliar treated with either a single application at a target rate of 12.5 g a.s./ha or two applications at a target rate of 12.5 g a.s./ha. Samples of sprouts were collected approximately 0, 3, 7 and 14 days after last the application. Residue analysis was performed according to BASF analytical method 567/0, which determines total cypermethrin residues by means of HPLC/MS-MS with a LOQ of 0.01 mg/kg.

Four trials were performed with the same emulsifiable concentrate formulation in the Southern European region. The product was applied at a rate of 25 g a.s./ha. Samples of brussels sprouts were collected approximately 0, 3, 7 and 14 days after last the application. Residue analysis was performed according to BASF analytical method 567/0, which determines total cypermethrin residues by means of HPLC/MS-MS with a LOQ of 0.01 mg/kg.

The trial data and residue results are summarized in Table 2.13.1-1.

Table 2.13.1-1: Residues in brussels sprouts

GAP for EU-N is 1-2 applications at 15 g a.s./ha at infestation as an overall spray, PHI = 7 (outdoor)

_ underlined values were used for MRL calculation

Findings:
The residue studies in brussels sprouts presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 2 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions – 8 trials conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions – 4 trials conducted in the Southern European region

After one application at 12.5 g a.s./ha, initial residues of alpha-cypermethrin in brussels sprouts ranged between <0.01 mg/kg and 0.019 mg/kg. Residues ranged at levels between <0.01 – 0.024 mg/kg, <0.01 – 0.016 mg/kg and <0.01 – 0.014 mg/kg at 3, 7 and 14 days after application.

After two applications at 12.5 g a.s./ha, initial residues ranged between <0.01 mg/kg and 0.051 mg/kg. Residues ranged at levels between <0.01 – 0.055 mg/kg, <0.01 – 0.046 mg/kg and <0.01 – 0.033 mg/kg at 3, 7 and 14 days after application.

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in brussels sprouts ranged between <0.01 mg/kg and 0.021 mg/kg. Residues declined to levels between <0.01 – 0.029 mg/kg, <0.01 – 0.023 mg/kg and <0.01 – 0.019 mg/kg at 3, 7 and 14 days after application.

Conclusion:

In 8 trials supporting the GAP for the Northern European region, residues ranged between <0.01 – 0.046 mg/kg at the target PHI of 7±1 days.
In 4 trials supporting the GAP for the Southern European region, residues ranged between <0.01 – 0.029 mg/kg at the target PHI of 3±1 days.

2.13.2 Estimation of MRL, HR and STMR for brussels sprouts

For *brussels sprouts*, the following residue studies were considered (BASF DocIDs): 2006/1026859 and 2007/1007943.

The following residue values (EU-N: PHI=7±1 days / EU-S: 3±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026859 (open field)	<0.01, 0.014, 0.017, 0.046	<0.01, 0.013
2007/1007943 (open field)	0.01, 0.018, 0.02, 0.025	<0.01, 0.029
OECD-MRL-calculation (open field)	**0.07 (n=8, STMR=0.018, HR=0.046)**	**0.06 (n=4, STMR=0.012, HR=0.029)**

_ underlined values were used for risk assessment purposes

Diehl M (2007): Study on the residue behaviour of BAS 310 I in head cabbage after treatment with BAS 310 40 I under open field conditions in Southern and Northern Europe, 2006; BASF DocID 2007/1013148

Material and Methods:

In the years 2003, 2005 and 2006 a residue program on head cabbage was conducted in Belgium, Denmark, France (Northern and Southern European region), Germany, Italy, Spain and the United Kingdom under field conditions.

During the 2003 growing season, a total of 4 trials was conducted in headed cabbage. An emulsifiable concentrate formulation of alpha-cypermethrin (SC 100 g a.s./L; BAS 310 11 I) was foliar sprayed on cabbage on two different plots. In one variant, one treatment was done with a rate of 15 g a.s./ha. This was compared to two treatments with the same application rate. The growth stage of the plants at the last application was between BBCH 47-48 (70-80% of the expected head size reached). Cabbage head specimens were collected directly after the last application as well as 2-3, 6-7 and 13-14 days thereafter.
The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS with BASF analytical method No. 546/0 which has a limit of quantitation of 0.05 mg/kg in all sample materials.

During the 2005 growing season, six field trials were conducted in different representative head cabbage growing areas in the United Kingdom, France (Northern and Southern European region), Italy and Germany.

In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to cabbage plants either once or twice to separate plots at a target rate of 12.5 g a.s./ha. The growth stage of the plants at application was between 43 (30% of the expected head diameter reached) and 47 (30% of the expected head diameter reached).

Specimens of cabbage heads were collected immediately after the last application from each plot, as well as 3, 7 and 14 days thereafter.

In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to cabbage plants once at a target rate of 25 g a.s./ha.

The growth stage of the plants at application was between 47 and 48 (70-80% of the expected head diameter reached).

Specimens of cabbage heads were collected immediately after the last application, as well as 3, 7 and 14 days thereafter.

Specimens were analysed using BASF analytical method No. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, six field trials were conducted in different representative head cabbage growing areas in Belgium, the United Kingdom, France (Northern and Southern European region), Spain and Germany.

In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to cabbage plants either once or twice to separate plots at a target rate of 12.5 g a.s./ha. The growth stage of the plants at application was between 44 (40% of the expected head diameter reached) and 48 (80% of the expected head diameter reached).

Specimens of cabbage heads were collected immediately after the last application from each plot, as well as 3-4, 7-8 and 14 days thereafter.

In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to cabbage plants once at a target rate of 25 g a.s./ha at a growth stage up to 48 (80% of the expected head diameter reached).

Specimens of cabbage heads were collected immediately after the last application, as well as 3, 6-7 and 13-14 days thereafter.

Specimens were analysed using BASF analytical method No. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.14.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in head cabbage presented in the alpha-cypermethrin dossier were carried out in 7 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 2 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions-8 trials including both variants, all conducted in the Northern European region
- one or two treatments at a target rate of 15 g a.s./ha under open field conditions-4 trials including both variants, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions-4 trials conducted in the Southern European region

After one or two treatments with alpha-cypermethrin at a rate of 15 g a.s./ha, no residues of alpha-cypermethrin above the limit of quantitation of the analytical method (LOQ; 0.05 mg/kg) were detected in any of the cabbage specimens analysed regardless the cabbage species or number of treatment.

After one application at 12.5 g a.s./ha, initial residues of alpha-cypermethrin in cabbage heads ranged between <0.01 mg/kg and 0.084 mg/kg. Residues declined to levels between <0.01-0.082 mg/kg, <0.01-0.062 mg/kg and <0.01-0.072 mg/kg 3, 7 and 14 days after application.

After two applications at 12.5 g a.s./ha, initial residues ranged between <0.01 mg/kg and 0.164 mg/kg. Residues declined to levels between <0.01-0.182 mg/kg, <0.01-0.105 mg/kg and <0.01-0.097 mg/kg at 3-4, 7-8 and 14 days after application.

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in cabbage heads ranged between <0.01 mg/kg and 0.045 mg/kg. Residues declined to levels between <0.01-0.013 mg/kg on days 3 and 6-7, respectively. No residues above the limit of quantitation of the analytical method (LOQ; 0.01 mg/kg) were found in any of the treated cabbage head samples 13-14 days after the last application.

Conclusion:

In the years 2003, 2005 and 2006 a residue program on head cabbage was conducted in Belgium, Denmark, France (Northern and Southern European region), Germany, Italy, Spain and the United Kingdom under field conditions.
In 8 trials supporting the GAP for the Northern European region, residues ranged between <0.01-0.105 mg/kg at the target PHI of 7 days.
In 4 trials supporting the GAP for the Southern European region, residues ranged between <0.01-0.013 mg/kg at the target PHI of 3 days.

2.14.2 Processing studies in head cabbage

Within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 this processing study in cabbage (AL-721-044) was submitted. The study was assessed as not being required (3rd Addendum to the Monograph: Addendum Chapter B-7 (Residue data), January 2003). Therefore, a review was not performed at this time. The study was not included in the application as it had been submitted already with the alpha-cypermethrin addendum dossier. Below it is summarized for the reviewer´s convenience.

Report:	Grolleau G. 2001a Alphacypermethrin (AC 900049) 150 g a.s./ WG (RLM 11203): At harvest residue study on alphacypermethrin in head cabbage and processed fractions (cooked and sauerkraut), Italy, 2000. BASF RDI No: AL-721-044 DocNo. 2001/7001643
Guidelines:	EEC 7029/VI/95 rev. 5,Decret No. 98-1312 (31-12-1998),EEC 1999/11/EC
GLP:	yes (certified by Groupe Interministeriel des Produits Chimiques, France)

Materials and Methods:

In 2000, a single residue trial was established in Italy. Savoy cabbage (variety: Famosa) was treated with the 150 g a.s./kg WG (RLM 11203) alpha-cypermethrin formulation.

In this trial, cabbage plants received either a single 100 g a.s./ha foliar application 7 days prior to typical commercial harvest or three 100 g a.s./ha foliar applications 21, 14, and 7 days prior to typical commercial harvest.

These exaggerated treatment rates were used in an effort to generate finite alpha-cypermethrin residues in cabbage so that any effects of processing on alpha-cypermethrin residues could be better quantitated.

Actual applications were within 10% of nominal and were applied at 960 L/ha. The single application occurred at the BBCH 47 (70% of the expected head size reached) growth stage; the last of the three applications also occurred at BBCH 47. Cabbage specimens were sampled at typical commercial harvest, 7 days following the single 100 g a.s./ha application (7 DAT1) and 7 days following the last of the three 100 g a.s./ha applications (7 DAT3).

Field samples collected for residue analysis were frozen within 24 hours of sampling and remained frozen (including during transportation) until analysis. These specimens were shipped frozen to CEM Analytical Services Ltd. (CEMAS), Glendale Park, Fernbank Road, North Ascot, Berkshire, UK.

Bulk cabbage samples, sufficient for processing, were shipped unfrozen to the processor [Viticulture Recherche et Developpement (VITI R & D).

The processing phase was conducted at VITI R&D, 101 impasse des Capitelles, VILLETELLE, France, according to VITI R&D Processing Phase Plan GRA 0006 EUR.

Specimen analysis was conducted at CEMAS, Glendale Park, Fernbank Road, North Ascot, Berkshire, UK. All specimens were homogenized with dry ice. Cabbage and cabbage process fraction specimens were analyzed using BASF Agro Research analytical method RLA 12513.03V entitled:

> "Analysis of Alphacypermethrin (AC 900049) in Vining Peas, Field Beans, Strawberries, Cherries and Green Beans."

This methodology has been validated with a 0.05 mg/kg alpha-cypermethrin LOQ in:

- BASF Agro Research report 4452 (study 98452V) for green beans;
- BASF Agro Research report 4454 (study 98332V) for strawberries;
- BASF Agro Research report 4453 (study 98330V) for cherries;

A method performance check was included with study AL-UK-00-972 (CEMR-1421) and validated the 0.05 mg/kg alpha-cypermethrin LOQ in cabbage substrates. A method performance check for sauerkraut was included with study AL-IT-00-605 (CEMR-1462) and validated the 0.05 mg/kg alpha-cypermethrin LOQ in cabbage process fractions.

Concurrent procedural recoveries at the LOQ [0.05 mg/kg] and 10 times the LOQ in cabbage and sauerkraut were within the acceptable 70% to 110% range.

Findings:

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any untreated cabbage specimens or processed fractions (cooked cabbage and sauerkraut) obtained from untreated cabbage specimens.

Alpha-cypermethrin residues, ranging from 0.57 mg/kg to 1.0 mg/kg were found in cabbage sampled 7 days after the single 100 g a.s./ha application; alpha-cypermethrin residues ranged from 0.90 mg/kg to 1.3 mg/kg in cabbage sampled 7 days after the third 100 g a.s./ha application.

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any process fractions (cooked cabbage and sauerkraut) obtained from cabbage taken 7 days after a single 100 g a.s./ha application or 7 days after the third 100 g a.s./ha application.

Cabbage processing procedure summary-cooked cabbage:

Outer leaves and cores were removed from approximately 3 kg savoy cabbage. The dressed cabbage was then shred into thin strips and blanched in boiling water (approximately 4 kg water/kg cabbage) for one minute.

Figure 2.14.2-1: Cooked cabbage processing procedure flowchart - DocID AL-721-044

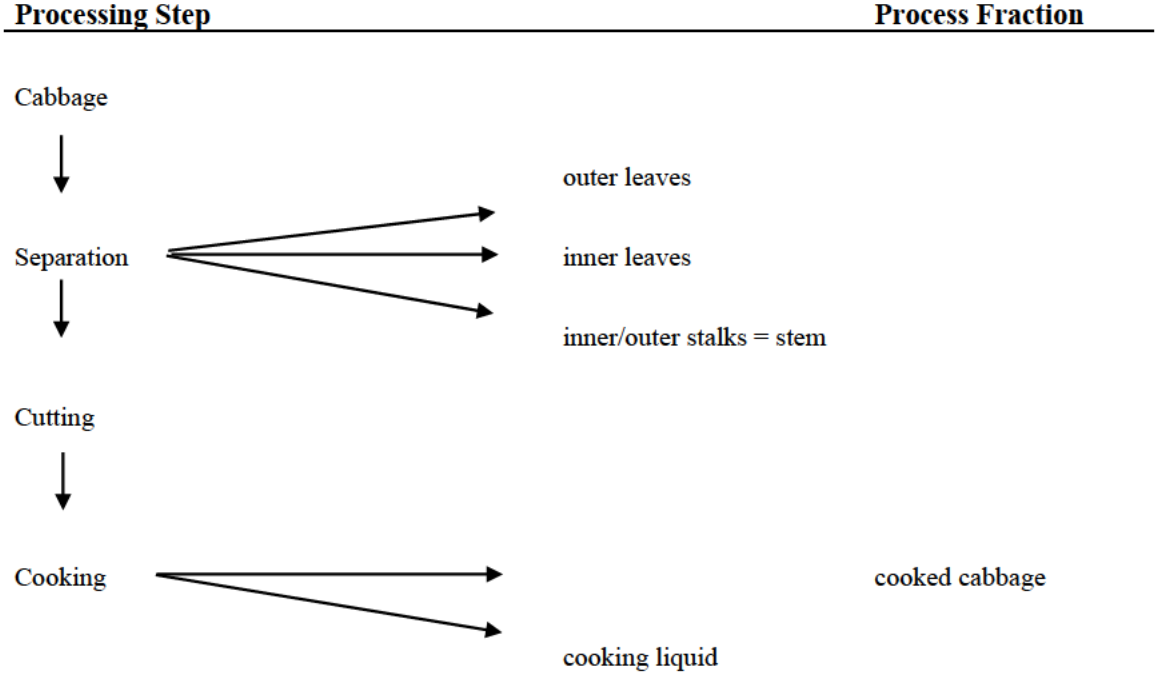

Table 2.14.2-1: Mass balance of the production of cooked cabbage - DocID AL-721-044

Processing Step	U1	T2	T3
weight of cabbage used for cooking process (kg)	3.05	3.10	3.25
dressed cabbage weight (kg)	1.70	0.80	2.00
waste weight (external leaves + core) (kg)	1.35	2.30	1.25
cut cabbage weight (kg)	1.00	0.60	0.75
blanched cabbage weight (kg)	1.10	0.70	0.80
U1 = untreated cabbage.			
T2 = cabbage treated at 1 x 100 g a.s./ha.			
T3 = cabbage treated at 3 x 100 g a.s./ha.			

Cabbage processing procedure summary - sauerkraut:

Outer leaves and cores were removed from approximately 15 kg savoy cabbage. The dressed cabbage was then shred into thin strips. Next cooking salt (25 g/kg cabbage) and lactic bacteria (0.03 g/kg cabbage) were added. Fermentation to sauerkraut followed and once fermentation was complete, the sauerkraut was pasteurized at 85°C for one minute.

Figure 2.14.2-2: Sauerkraut processing procedure flowchart - DocID AL-721-044

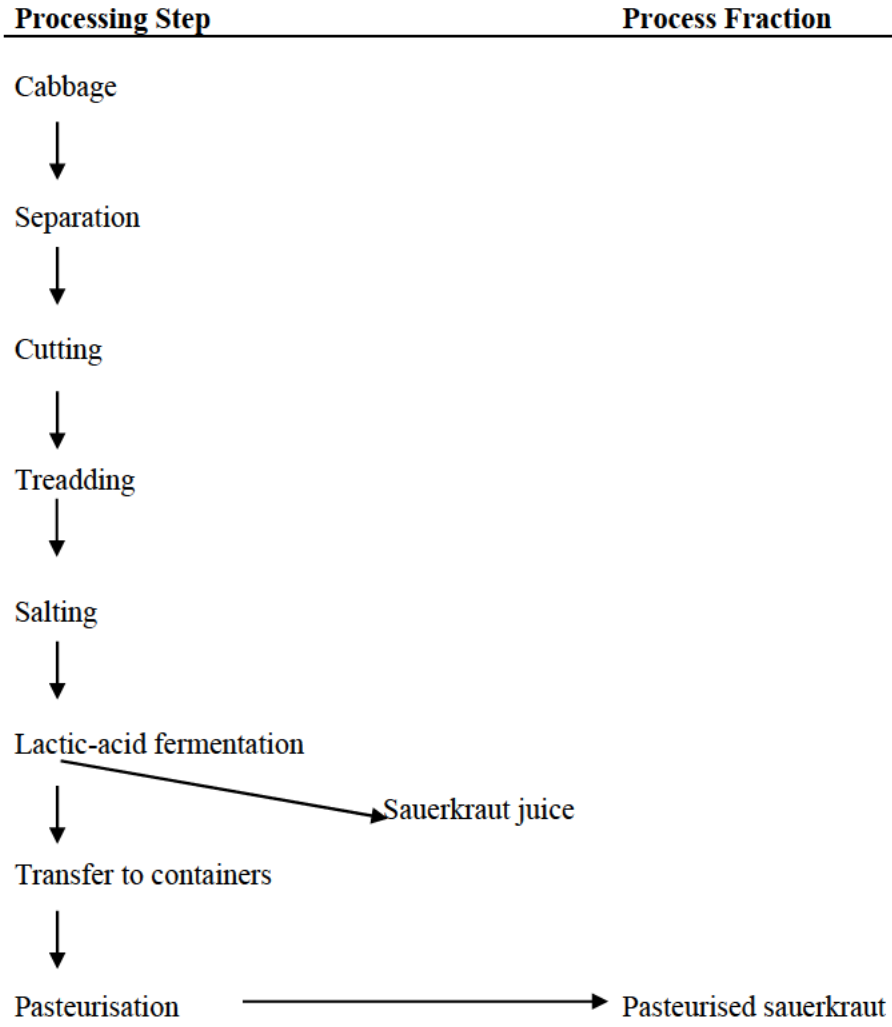

Table 2.14.2-2: Mass balance of the production of sauerkraut - DocID AL-721-044

Processing Step	U1	T2	T3
weight of cabbage used for sauerkraut process (kg)	15.20	15.15	15.30
dressed cabbage weight (kg)	4.30	3.35	4.40
waste weight (external leaves + core) (kg)	10.75	11.80	10.80
cut cabbage weight (kg)	2.05	2.40	2.95
sauerkraut weight (kg)	1.95	2.25	2.60
U1 = untreated cabbage.			
T2 = cabbage treated at 1 x 100 g a.s./ha.			
T3 = cabbage treated at 3 x 100 g a.s./ha.			

Table 2.14.2-3: Transfer factors for cooked cabbage and sauerkraut - DocID AL-721-044

	alpha-cypermethrin residue found (mg/kg)		Transfer Factor	
	T2	T3	T2	T3
cabbage (RAC)*	0.57	0.90	1	1
cabbage (RAC)**	1.00	1.33	1	1
cooked cabbage	<0.05	<0.05	<1	<1
sauerkraut	<0.05	<0.05	<1	<1
* cabbage taken from the field.				
**unprocessed cabbage sampled at the processor.				
U1 = untreated cabbage.				
T2 = cabbage treated at 1 x 100 g a.s./ha.				
T3 = cabbage treated at 3x 100 g a.s./ha.				

Conclusion:

The data from this processing study demonstrate clearly that there is little or no likelyhood of detectable alpha-cypermethrin residues resulting in the edible process fractions from cabbage treated at the GAP proposed rate.

Within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 this processing study in cabbage (DocID 2002/1004078) was submitted. The study was assessed as not being required (3rd Addendum to the Monograph: Addendum Chapter B-7 (Residue data), January 2003). Therefore, a review was not performed at this time. The study was not included in the application as it had been submitted already with the alpha-cypermethrin addendum dossier. Below it is summarized for the reviewer´s convenience.

Report:	Pollmann B. 2002a Determination of residues of alphacypermethrin in field samples and in processed goods after application of BAS 310 08 I in head cabbage at 3 sites in Germany in 2001. 2002/1004078

GLP:	yes (certified by Ministerium für Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Materials and Methods:

In 2001, three residue trials were established in Germany; two trials in Northern Germany [variety: Krautmann (G01N063R) and variety: Megatonn (G01N064R)] and one trial in Southern Germany [variety: Custello (G01N065R)]. Each trial was treated with the 150 g a.s./kg WG (BAS 310 08 I) alpha-cypermethrin formulation. In all three residue trials, cabbage received three 100 g a.s./ha foliar applications 21, 13 (G01N065R) or 14 (G01N063R and G01N064R), and 7 (G01N065R) or 6 (G01N063R and G01N064R) days prior to typical commercial harvest. This exaggerated treatment rate was used in an effort to generate finite alpha-cypermethrin residues in cabbage so that any effects of processing on alpha-cypermethrin residues could be better quantitated.

Actual applications were within 10% of nominal, ranging from 97 g a.s./ha to 111 g a.s./ha. The last of three applications occurred at BBCH 46 for G01N063R (50% of the expected head size reached), BBCH 47 for G01N064R (70% of the expected head size reached), and BBCH 48 for G01N065R (>70% of the expected head size reached). Application volumes ranged from 567 L/ha to 647 L/ha. Cabbage specimens were sampled immediately after (0+ DAT3) the last of the three applications and 7 days after the third application (7 DAT3), at typical commercial harvest.

Field samples for residue analysis from the three trials were frozen within 24 hours of sampling and remained frozen (including during transportation) until analysis. These specimens were shipped frozen to GAB (Niefern-Öschelbronn), where they were stored until shipment to the analytical laboratory.

Bulk cabbage from all three trials (G01N063R, G01N064R, and G01N065R), sufficient for processing, were shipped unfrozen to the processor, GAB (Niefern-Öschelbronn).

The processing phase for cooked cabbage was conducted by GAB (Niefern-Öschelbronn), while the sauerkraut processing was conducted by Forschungsanstalt Geisenheim, Fachgebiet Weinanalytik und Getränkeforschung, Geisenheim, Germany.

Specimen analysis was conducted at the BASF Agricultural Research Center, Limburgerhof, Crop Protection Division, Ecology and Environmental Analytics, APD/MC. The cabbage and cabbage process fraction specimens were analyzed using BASF method 989/1 (BASF Agro Research analytical method RLA 12513.03V with minor modifications) entitled:

> "Analysis of Alphacypermethrin (AC 900049) in Vining Peas, Field Beans, Strawberries, Cherries and Green Beans."

This methodology has been validated with a 0.05 mg/kg alpha-cypermethrin LOQ in:

- BASF Agro Research report 4452 (study 98452V) for green beans;
- BASF Agro Research report 4454 (study 98332V) for strawberries;
- BASF Agro Research report 4453 (study 98330V) for cherries;

A method performance check was included with study AL-UK-00-972 (CEMR-1421) and validated the 0.05 mg/kg alpha-cypermethrin LOQ in cabbage. A method performance check for sauerkraut was included in this study and validated the 0.05 mg/kg alpha-cypermethrin LOQ in cabbage process fractions.

Concurrent procedural recoveries at the LOQ [0.05 mg/kg] and 10 times the LOQ [in cabbage, inner and outer cabbage leaves, cabbage stems, cooking liquid, sauerkraut, and sauerkraut juice] were acceptable however, not all individual recoveries were within the 70% to 110% range. None-the-less, the overall alpha-cypermethrin procedural recovery at both levels in all substrates was 100% ± 22%, considering the methodology was optimized for all substrates.

Findings:

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any untreated cabbage specimens or processed fractions (outer leaves, inner leaves, stem, cooked cabbage, cooking liquid, sauerkraut, and sauerkraut juice) obtained from untreated cabbage specimens.

Trace alpha-cypermethrin residues, ranging from <0.05 mg/kg (method LOQ) to 0.07 mg/kg were found in cabbage sampled immediately after the third 100 g a.s./ha application.

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in cabbage sampled 6 days after the third 100 g a.s/kg application (G01N063R and G01N064R) or 7 days after the third 100 g a.s/kg (G01N065R) .

With the exception of the outer cabbage leaves, no detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any process fractions (inner leaves, stem, cooked cabbage, cooking liquid, sauerkraut, and sauerkraut juice) obtained from cabbage sampled 6 days after the third 100 g a.s/kg application (G01N063R and G01N064R) or 7 days after the third 100 g a.s/kg (G01N065R) .

Trace alpha-cypermethrin residues, ranging from 0.15 mg/kg to 0.27 mg/kg were found in the outer leaves obtained from cabbage sampled 6 days after the third 100 g a.s/kg application (G01N063R and G01N064R) or 7 days after the third 100 g a.s/kg (G01N065R) .

Table 2.14.2-6: Transfer factors for cooked cabbage and sauerkraut - DocID 2002/1004078

	alpha-cypermethrin residue found (mg/kg)			Transfer Factor		
	11-G01N063R	5-G01N064R	11-G01N065R	11-G01N063R	5-G01N064R	11-G01N065R
Cabbage (RAC)*	<0.05	<0.05	<0.05	1	1	1
Sauerkraut	<0.05	<0.05	<0.05	<1	<1	<1
Sauerkraut juice	<0.05	<0.05	<0.05	<1	<1	<1
Cabbage (RAC)*	<0.05	<0.05	<0.05	1	1	1
Outer leaves	0.17	0.27	0.15	cannot be calculated**		
Inner leaves	<0.05	<0.05	<0.05	<1	<1	<1
Stems	<0.05	<0.05	<0.05	<1	<1	<1
Cooked cabbage	<0.05	<0.05	<0.05	<1	<1	<1
Cooking liquid	<0.05	<0.05	<0.05	<1	<1	<1

* The treated cabbage samples used for the residue determination (RAC) were: 9-G01N063R, 3-G01N064R, and 9-G01N065R, respectively.

* No transfer factor could be determined--no detectable residue in the RAC cabbage. However, these cabbage plants received 30 times the maximum single seasonal application, therefore adjusting for the exaggeration would result in no detectable (<0.05 mg/kg) alpha-cypermethrin residues in the outer cabbage leaf fraction.

Conclusion:

The data from this processing study demonstrate clearly that there is little or no likelyhood of detectable alpha-cypermethrin residues resulting in the edible process fractions or processing waste steams from cabbage treated at the GAP proposed rate.

2.14.3 Estimation of MRL, HR and STMR for head cabbage

For *head cabbage*, the following residue studies were considered (BASF DocIDs): 2004/1006470, 2006/1026852 and 2007/1013148.

The following residue values (PHI=7±1 days for EU-N, PHI=3±1 days for EU-S. or later if higher residues occured) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2004/1006470 (field)	<0.05 (4x)	-
2006/1026852 (field)	<0.01, 0.014, 0.018, 0.104	<0.01, 0.013
2007/1013148 (field)	<0.01 (3x), 0.105	0.010, 0.013
OECD-MRL-calculation	**0.2 (n=12, STMR=0.034, HR=0.105)**	**0.03 (4, STMR=0.013, HR=0.012)**

_ underlined values were used for risk assessment purposes

2.15 Leafy brassica

Besidues the new studies presented in Section M-CA 6.3, no additional residue data were considered for leafy brassica.

2.16 Lettuce

In the framework of the original inclusion of alpha-cypermethrin into AnnexI of Directive 91/414; residue studies in lettuce were peer-reviewed. Below, peer reviewed data supporting the current GAP and considered for MRLproposal and risk assessment are summarized. New trials are presented inSection M-CA 6.3.3; the MRL calculations are shown in Section M-CA 6.7. Additional glasshouse and field data are also presented below.

Table 2.16-1: Number of residue trials conducted per geographical region and vegetation period

Crop	Vegetation Period	Number of Trials					Report-No.
		EU North	Country	EU South	Country	Total

2.16.1 Supervised residue trials in lettuce

In the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414; residue studies in lettuce were peer-reviewed. Below, residue data from peer-reviewed trials supporting the current GAP and considered for MRL proposal and risk assessment are summarized. New trials are presented in Section M-CA 6.3.4; the MRL calculations are shown in Section M-CA 6.7.

Lamb´s lettuce

Two indoor trials were performed in lamb´s lettuce in France (Northern European region) in 1992. A 50 g a.s./L formulation of alpha-cypermethrin was applied twice at a target rate of 10 g a.s./ha. Lettuce leaves were sampled 7 days after the last application. Residues in leaves ranged between 0.283 and 0.294 mg/kg.

The trial data and residue results are summarised in Table 2.16.1-2.

Lettuce

Two open field trials were carried out in France (Southern European region) in 1981 using one application of alpha-cypermethrin (100 g a.s./L EC) at rates of 9 or 15 g a.s./ha. Lettuce was sampled immediately after application as well as 3 and 10 days afterwards.
After 9 g a.s./ha, residues in the lettuce immediately after application were 0.31 mg/kg falling to 0.21 and 0.12 mg/kg after 3 and 10 days, respectively. After 15 g a.s./ha, residues in the lettuce immediately after application were 0.41 mg/kg falling to 0.28 and 0.17 mg/kg after 3 and 10 days, respectively.

During the 2003 growing season, a total of 4 trials was conducted in head lettuce. BAS 310 03 I and BAS 310 QC I, both soluble concentrate formulations of alpha-cypermethrin (SC; 100 g a.s./L) were foliar applied once at a rate of 9 g a.s./ha to head lettuce plants on separate plots. The growth stages of the plants were between 45 (50% of the expected head size reached) and 49 (typical size, form and firmness of heads reached) at application.
Head lettuce specimens were collected directly after the application from each plot at all locations as well as 3 and 7 days thereafter.
The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS with BASF analytical method No. 546/0 which has a limit of quantitation of 0.05 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.16.1-1

Eight glasshouse trials were performed in the year 2005 in Belgium, Denmark, France (Southern European region), Germany, Greece, Italy and Spain to determine the magnitude of the residue after application of a 100 g a.s./L emulsifiable concentrate formulation of alpha-cypermethrin (EC; BAS 310 40 I). The product was foliar applied once at a rate of 40 g a.s./ha. The growth stage of the plants at application was between 41 (heads begin to form: the two youngest leaves do not unfold) and 47 (70% of the expected head size reached).
Samples of lettuce heads were collected 0, 2-4, 6-8 and 13-14 days after application. The specimens were analysed for total cypermethrin residues by means of HPLC-MS/MS with BASF analytical method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.16.1-1

Report:	**Klaas P.,Ziske J., 2009d**
Title:	Study on the residue behaviour of Alpha-Cypermethrin in lettuce after treatment with BAS 310 51 I and BAS 310 40 I under field conditions in Germany, The Netherlands, Southern France and Italy, 2008
Document No:	BASF DocID 2009/1090703
Guidelines:	EEC 91/414 Annex III (Part A Section 8), EEC 91/414 Annex II (Part A Section 6), EEC 7029/VI/95 rev. 5, EEC 7525/VI/95 rev. 7, EEC 1607/VI/97 rev. 2 10.06.1999
GLP	yes

Executive Summary

During the growing season of 2008, four field trials with lettuce (field conditions) were conducted in Northern and Southern Europe, in order to determine the magnitude of the residues of BAS 310 I (alpha-cypermethrin) after treatment with BAS 310 51 I and BAS 310 40 I.
Each field trial consisted of three plots:
Trials L080177 (Germany) and L080178 (The Netherlands):
Plot 1: Control
Plot 2: Treated twice with 0.3 L/ha of BAS 310 51 I (15.0 g/ha of BAS 310 I, ME formulation)
Plot 3: Treated twice with 0.15 L/ha of BAS 310 40 I (15.0 g/ha of BAS 310 I, EC formulation)
Trials L080179 (France-South) and L080180 (Italy):
Plot 1: Control
Plot 2: Treated once with 0.6 L/ha of BAS 310 51 I (30.0 g/ha of BAS 310 I, ME formulation)
Plot 3: Treated once with 0.3 L/ha of BAS 310 40 I (30.0 g/ha of BAS 310 I, EC formulation)
The applications took place 13-15 days before harvest (DBH) and 7 DBH on trials L080177 and L080178 and 6-7 DBH on trials L080179 and L080180 with a spray volume of 400 L/ha of spray.
Alpha-cypermethrin was extracted from specimens according to an adaption of BASF Method No. 567/0 (L0020/01) with a limit of quantitation (LOQ) of 0.01 mg/kg. The analytical results demonstrate that the treatment with BAS 310 51 I and BAS 310 40 I did not lead to significantly different residue levels in the raw agricultural commodity at harvest.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 51 I
BAS 310 40 I
Lot/Batch #: BAS 310 51 I, 101156, alpha-cypermethrin: 50 g a.s./L
BAS 310 40 I, 1209, alpha-cypermethrin: 100 g a.s./L
Purity:
CAS#: 67375-30-8
Development code:
Spiking levels: 0.01-1.00 mg/kg

2. Test Commodity:

Crop: Lettuce
Type: Leaf vegetable
Variety: Tizian, Santoro, Fortina, Noisette
Botanical name: *Lactuca sativa*
Crop parts(s) or processed
Commodity: Head
Sample size: 12 units/1.0-2.0 kg

B. STUDY DESIGN

1. Test procedure

During the 2008 growing season, a total of four open field trials were conducted in lettuce in Germany, The Netherlands, Southern France and Italy.
The objective of the study was to determine the magnitude of alpha-cypermethrin residues in lettuce after application of the formulations BAS 310 51 I (ME) and BAS 310 40 I (EC). The additional objective was the comparison of the residue levels after the application of the EC and the ME formulation.
Each field trial consisted of three plots (one control plot, plot 1), one plot treated with BAS 310 51 I (plot 2) and another plot treated with BAS 310 40 I (plot 3). In two of four trials (L080177 and L080178) on the treated plot 2, BAS 310 51 I was applied twice at a rate targeting 0.3 L product/ha, equal to 15 g alpha-cypermethrin/ha and on the treated plot 3, BAS 310 40 I was applied twice at a rate targeting 0.15 L product/ha, equal to 15 g alpha-cypermethrin/ha. The applications were made targeting 14±1 days and 7±1 days before harvest.
For the other two trials trials (L080179 and L080180) on the treated plot 2, BAS 310 51 I was applied once at a rate targeting 0.6 L product/ha, equal to 30 g alpha-cypermethrin/ha and on the treated plot 3, BAS 310 40 I was applied once at a rate targeting 0.3 L product/ha, equal to 30 g alpha-cypermethrin/ha. The applications were made targeting 7±1 days before harvest. Both formulations were applied with the same GAP.

0 DALA (days after last application) sampling in the untreated plot was performed. The treated lettuce specimens (head) were taken from both plots immediately after the last application (0 DALA). Untreated and treated specimens were additionally collected 3±1, 7±1 and 14±1 DALA.

Table 2.16.1-3: Target application rates and timings for lettuce

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (g a.s./ha)	Water Volume (L/ha)	Target Date/ Timing

		1				30		
	4	2	F	BAS 310 40 I	alpha-cypermethrin	15	400	7±1, 14±1 days before harvest
		1				30		

2. Description of analytical procedures

Alpha-cypermethrin was extracted from specimens according to an adaption of BASF Method No. 567/0 (L0020/01) with a limit of quantitation (LOQ) of 0.01 mg/kg.
The residues of alpha-cypermethrin in lettuce specimens were extracted from plant matrices using a mixture of methanol, water and HCl 2 mol/L. For clean-up a liquid/liquid partition against cyclohexane was used. The final determination of alpha-cypermethrin was performed by LC-MS/MS.

Table 2.16.1-4: Summary of recoveries for alpha-cypermethrin in lettuce

Matrix	Fortification Level (mg/kg)	Summary Recoveries		
		n	Mean (%)	RSD (%)
BASF Method No. 567/0		**alpha-cypermethrin (BAS 310 I)**		
lettuce (head)		8	100	7

II. RESULTS AND DISCUSSION

Directly after the last application (0 DALA) of BAS 310 51 I (plot 2), alpha-cypermethrin residues were 0.29-0.66 mg/kg. At 3±1 days after the last application, residues were 0.10-0.35 mg/kg, at 7±1 days after the last application residues were 0.07-0.33 mg/kg, and at 14±1 days after the last application, residues were 0.02-0.10 mg/kg.
Directly after the last application (0 DALA) of BAS 310 40 I (plot 3), alpha-cypermethrin residues were 0.36-0.46 mg/kg. At 3±1 days after the last application, residues were 0.14-0.22 mg/kg, at 7±1 days after the last application residues were 0.13-0.15 mg/kg, and at 14±1 days after the last application, residues were 0.03-0.12 mg/kg.
An overall summary of the residues is given in the table below.

Table 2.16.1-5: Summary of residues in lettuce after application of BAS 310 51 I or BAS 310 40 I

Crop	Year	No. of Appl.	Application	DALA[1)]	BBCH[2)]	Range of Residues (mg/kg)

2) BBCH stage at respective sampling

III. CONCLUSION

The analytical results demonstrate that the treatment with BAS 310 51 I and BAS 310 40 I did not lead to significantly different residue levels in the raw agricultural commodity at harvest.

GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Material and Methods:

In the years 2005 and 2006 a residue program on spinach was conducted in the field in France (Northern European region), Germany and the Netherlands.
During the 2005 growing season, one field trial in spinach was conducted in the Netherlands. BAS 310 40 I, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L), was foliar applied to separate plots of spinach either once or twice at a target rate of 12.5 g a.s./ha. The last treatment was performed at growth stage 13 (3rd true leaf unfolded). Specimens of spinach leaves were collected immediately after the last application from each plot as well as 3, 7, and 14 days thereafter. The specimens were analysed using BASF method no. 567/0, which quantifies the residues of underivatised cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

In the year 2006, three residue trials were conducted in France (Northern European region) and Germany. A 100 g a.s./L emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I) was foliar applied to separate plots of spinach plants either as a single application at a target rate of 12.5 g a.s./ha or twice at a target rate of 12.5 g a.s./ha. The growth stage of the plants was between 35 (leaf rosette has reached 50% of the expected diameter typical for the variety) and 49 (typical leaf mass reached) at the last application. Samples of spinach foliage were collected 0, 3, 7 and 14 days after the last application in all trials.
Residue analysis was performed according to BASF analytical method No. 567/0 which determines total cypermethrin residues by means of HPLC-MS/MS with a LOQ of 0.01 mg/kg.

The trial data and residue results are summarised in Table 2.17.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in spinach presented in the alpha-cypermethrin dossier were carried out in 3 different EU countries and provide data relevant to conditions in the Northern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions-4 trials including both variants, all conducted in the Northern European region

After one application at 12.5 g a.s./ha, initial residues of alpha-cypermethrin in spinach foliage ranged between 0.55 mg/kg and 1.1 mg/kg. Residues declined to levels between 0.220-0.81 mg/kg, 0.179-0.71 mg/kg and 0.037-0.84 mg/kg 3, 7 and 14 days after application.

After two applications at 12.5 g a.s./ha, initial residues spinach foliage ranged between 0.61 mg/kg and 1.9 mg/kg. Residues declined to levels between 0.33-1.4 mg/kg, 0.135-1.11 mg/kg and 0.033-0.96 mg/kg 3, 7 and 14 days after application.

Conclusion:

In the years 2005 and 2006 a residue program on spinach was conducted in the field in France (Northern European region), Germany and the Netherlands.
In 4 trials supporting the GAP for the Northern European region, residues in spinach ranged between 0.135-1.11 mg/kg at the target PHI of 7 days.

Title:	Residue behaviour of Alpha-Cypermethrin in/on fennel (bulbs formed by leafs stems), curly kale (leaves), blanched celery (stems) and spinach (leaves) outdoor after application of Fastac SC Super Contact (SC, 100 g/L) in Germany, 2006
Document No:	BASF DocID 2007/1035745
Guidelines:	none
GLP	yes

Executive Summary

During the growing season 2006 residue decline, shortened decline and harvest trials, were performed in fennel (bulbs formed by leaf stems), curly kale (leaves), blanched celery (stems) and spinach (leaves) as field trials on several sites in Germany.
Fastac SC Super Contact (alpha-cypermethrin, SC 100) was applied foliar 2 times at rates of 0.125 L product per hectare (12.5 g/ha alpha-cypermethrin) during growing season. The trials were conducted in order to determine the magnitude of the residues of the active ingredients in or on fennel (bulbs formed by leaf stems), curly kale (leaves), blanched celery (stems) and spinach (leaves). The samples were collected 0 - 7 -10 -14 (decline curves), 0 - 7 -14 (shortened decline study) and 14 days (harvest trials) after last application, respectively.
The samples were analysed for alpha-cypermethrin with modified method DFG S19. The limit of quantification (LOQ) was 0.010 mg/kg (alpha-cypermethrin).
Average recoveries from untreated samples, fortified with alpha-cypermethrin were 69 - 105 % in fennel and 74 - 92 % in curly kale at fortification levels between 0.01 mg/kg and 0.10 mg/kg. In blanched celery the recoveries were 75 - 110 % at fortification levels between 0.01 mg/kg and 0.5 mg/kg. In spinach the recoveries were 90 -100 % at fortification levels between 0.01 mg/kg and 1.0 mg/kg.
In context of this summary, only the results of alpha-cypermethrin for spinach are reported.
Residues of alpha-cypermethrin were at 7 DALA in spinach leaves in the range of 0.36 to 0.48 mg/kg.

Sample size:	min. 0.5 kg

B. STUDY DESIGN

1. Test procedure

During the growing season 2006 residue decline, shortened decline and harvest trials, were performed in fennel (bulbs formed by leaf stems), curly kale (leaves), blanched celery (stems) and spinach (leaves) as field trials on several sites in Germany.

Fastac SC Super Contact (alpha-cypermethrin, SC 100) was applied foliar 2 times at rates of 0.125 L product per hectare (12.5 g/ha alpha-cypermethrin) during growing season. The trials were conducted in order to determine the magnitude of the residues of the active ingredients in or on fennel (bulbs formed by leaf stems), curly kale (leaves), blanched celery (stems) and spinach (leaves). The samples were collected 0 - 7 -10 -14 (decline curves), 0 - 7 -14 (shortened decline study) and 14 days (harvest trials) after last application, respectively.

Table 2.17.1-2: Target application rates and timings for spinach

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2006	4	2	F	BAS 310 41 I (SC)	alpha-cypermethrin	0.0125	300-600	n r.

n r. not reported

2. Description of analytical procedures

The samples were analysed for alpha-cypermethrin with modified method DFG S19. The limit of quantification (LOQ) was 0.010 mg/kg (alpha-cypermethrin).
Average recoveries from untreated samples, fortified with alpha-cypermethrin were 69 - 105 % in fennel and 74 - 92 % in curly kale at fortification levels between 0.01 mg/kg and 0.10 mg/kg. In blanched celery the recoveries were 75 - 110 % at fortification levels between 0.01 mg/kg and 0.5 mg/kg. In spinach the recoveries were 90 - 100 % at fortification levels between 0.01 mg/kg and 1.0 mg/kg.
Alpha-cypermethrin: the samples were analysed for alpha-cypermethrin by the method DFG S 19 modified. The samples are extracted with acetone/water 2+1 (v+v) with subsequent extraction with cyclohexane/ethyl acetate 1+1 (v+v) and partition into acetone/cyclohexane/ethyl acetate. The extracts are cleaned up by gel permeation cbromatography on a Bio Beads SX-3 column followed by a silica gel fractionation. The residues are determined by gas chromatography using an electron capture detector. The quantification is done by external standardisation. The residues are not corrected for the recovery rates.

Table 2.17.1-3: Summary of recoveries of alpha-cypermethrin in spinach leaves

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
DFG S 19 (modified)		alpha-cypermethrin			
spinach leaves	0.01 / 0.1 / 1.0	7	94.1	3.9	3.7

II. RESULTS AND DISCUSSION

In context of this summary, only the results of alpha-cypermethrin for spinach are reported.
Residues of alpha-cypermethrin were at 7 DALA in spinach leaves in the range of 0.36 to 0.48 mg/kg.

Table 2.17.1-4: Summary of residues of BAS 310 I in spinach from trials according to critical GAP after application of BAS 310 41 I

Crop	Year	No. of Appl.	Application	DALA	BBCH	Residues Found (mg/kg)	
						Matrix	Alpha-Cypermethrin (BAS 310 I)
Spinach	2006	2	BAS 310 41 I (SC)	7±1	16-49	leaves	0.36 - 0.48

DALA = days after last application
BBCH = growth stage at respective sampling

III. CONCLUSION

After 2 applications of SC-formulation BAS 310 41 I at rates of 0.0125 kg alpha-cypermethrin/ha, residues in curly kale leaves were at the day of the last application in the range of 0.24 to 0.60 mg/kg. Fourteen days later (at 14 DALA), residues were still ranging between 0.05 and 0.19 mg/kg.

Table 2.17.1-5: Residues of BAS 310 I after two applications of the formulation BAS 310 41 I in Northern Europe

2.17.2 Estimation of MRL, HR and STMR for spinach

For *spinach*, the following residue studies were considered (BASF DocIDs): 2006/1026849, 2007/1007944 and 2007/1035745.

The following residue values (PHI=7±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026849	0,135	-
2007/1007944	0.185, 0.891, 1.113	-
2007/1035745	0.36, 0.46, 0.47, 0.48	-
OECD-MRL-calculation	**2.0 (n=8, STMR=0.465, HR=1.113)**	**-**

_ underlined values were used for risk assessment purposes

2.18 Green beans with pods

Residue data from supervised trials in green beans with pods were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.18-1: Number of residue trials conducted per geographical region and vegetation period

Jones G (2007): Study on the residue behaviour of alpha-cypermethrin in green beans (Phaseolus sp.) after treatment with BAS 310 40 I under field conditions in Northern and Southern Europe during 2005; BASF DocID 2006/1026857

Oxspring S (2007)

Full study reference

Oxspring S (2007): Study on the residue behaviour of alpha-cypermethrin in green beans *(Phaseolus sp.)* after treatment with BAS 310 40 I under field conditions in Northern and Southern Europe during 2006; BASF DocID 2007/1007950

Material and Methods:

In the years 2005 and 2006 a residue program on green beans was conducted in Belgium, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom under open field conditions.

During the 2005 growing season, eight field trials were performed in green beans in France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom.
In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to bean plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last application was between 69 (end of flowering) and 79 (pods: individual beans easily visible).
In four trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to bean plants once at a target rate of 25 g a.s./ha at growth stages between 71 (10% of pods have reached typical length/beginning of pot development) and 78 (80% of pods have reached typical length).
Specimens of beans with pods and remaining plant were collected immediately after the last application from each plot, as well as approximately 3, 7 and 14 days thereafter.
Specimens were analysed using BASF analytical method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, eight field trials were conducted in green beans in Belgium, France (Northern and Southern European region), Greece, Italy, Spain, the Netherlands and the United Kingdom.
In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to bean plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last application was between 76 (60% of pods have reached typical length) and 79 (Pods: individual beans easily visible).
In four trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to bean plants once at a target rate of 25 g a.s./ha. The growth stage of the plants at application was between 77 (70% of pods have reached typical length, pods still break cleanly) and 86 (60% of pods ripe (beans hard)).
Specimens of beans with pods and remaining plant were collected immediately after the last application from each plot, as well as 3-4, 7-8 and 14 days thereafter.
Specimens were analysed using BASF analytical method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.18.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in green beans presented in the alpha-cypermethrin dossier were carried out in 8 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 2 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions-8 trials including both variants, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions-8 trials conducted in the Southern European region

After one application at 12.5 g a.s./ha, initial residues in bean plant material ranged between 0.248 mg/kg and 0.861 mg/kg. Residues declined to levels between 0.076-0.249 mg/kg, 0.034-0.138 mg/kg and <0.01-0.083 mg/kg at 3-4, 7-8 and 14 days after application. In beans with pods, initial residues ranged between <0.01 mg/kg and 0.052 mg/kg. Residues declined to levels between <0.01-0.028 mg/kg, <0.01-0.031 mg/kg and <0.01-0.020 mg/kg at 3-4, 7-8 and 14 days after application.

After two applications at 12.5 g a.s./ha, initial residues in bean plant material ranged between 0.328 mg/kg and 0.816 mg/kg. Residues declined to levels between 0.123-0.344 mg/kg, 0.077-0.177 mg/kg and 0.055-0.135 mg/kg at 3-4, 7-8 and 14 days after application. In beans with pods, initial residues in ranged between <0.01 mg/kg and 0.048 mg/kg. Residues declined to levels between 0.011-0.031 mg/kg, <0.01-0.026 mg/kg and <0.01-0.014 mg/kg at 3-4, 7-8 and 14 days after application.

After one application at 25 g a.s./ha, initial residues in bean plant material ranged between 0.504 mg/kg and 1.551/1.504 mg/kg. Residues declined to levels between 0.198-1.013 / 0.978 mg/kg, 0.040-0.426 mg/kg and 0.021-0.245 mg/kg at 3, 7-8 and 14 days after application. In beans with pods, initial residues in ranged between 0.014 mg/kg and 0.064 mg/kg. Residues declined to levels between 0.013-0.063 mg/kg, <0.01-0.033 mg/kg and <0.01-0.021 mg/kg at 3, 7-8 and 14 days after application.

Conclusion:

In the years 2005 and 2006 a residue program on green beans was conducted in Belgium, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom under open field conditions.
In 8 trials supporting the proposed field GAP for the Southern European region, residues in bean plant material ranged between 0.198-1.013 / 0.978 mg/kg at the target PHI of 3 days and between 0.040-0.426 mg/kg at the target PHI of 7±1 days. Residues in beans with pods ranged between 0.013-0.063 mg/kg at the target PHI of 3 days and between <0.01-0.033 mg/kg at the target PHI of 7±1 days.

2.18.2 Estimation of MRL, HR and STMR for green beans with pods

For *green beans with pods*, the following residue studies were considered (BASF DocIDs): 2006/1026857 and 2007/1007950.

The following residue values (PHI=7±1 days for EU-N or PHI=3±1 days for EU-S, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026857	0.11, 0.014, 0.015, 0.026	0.018, 0.020. 0.028, 0.063
2007/1007950	<0.01, 0.017, 0.018, 0.019	0.028, 0.039, 0.045, 0.050
OECD-MRL-calculation	**0.05 (n=8, STMR=0.016, HR=0.026)**	**<u>0.15</u> (n=8, STMR=0.034, HR=0.063)**

_ underlined values were used for risk assessment purposes

2.19 Green peas without pods

Residue data from supervised trials in green peas without pods were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.19-1: Number of residue trials conducted per geographical region and vegetation period

Oxspring S (2007): Study on the residue behaviour of alpha-cypermethrin in fresh green peas (field) after treatment with BAS 310 40 I under field conditions in Northern and Southern Europe during 2006; BASF DocID 2007/1007951

Material and Methods:

In the years 2005 and 2006 a residue program on peas was conducted in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom under open field conditions.

During the 2005 growing season, six field trials were conducted in fresh peas in France (Northern European region), Germany, Greece, Italy, the Netherlands and the United Kingdom.
In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last application was between 76 (60% of pods have reached typical length; juice exudes if pressed. Tenderometer value: 115 TE) and 79 (Pods have reached typical size (green ripe); peas fully formed).
In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea plants once at a target rate of 25 g a.s./ha at growth stages between 74 (40% of pods have reached typical length; juice exudes if pressed. Tenderometer value: 95 TE) and 79.
Specimens of peas and remaining plant were collected immediately after the last application from each plot, as well as approximately 3, 7 and 14 days thereafter.
Specimens were analysed using BASF analytical method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, six field trials were conducted in fresh peas in Denmark, France (Southern European region), Germany, Spain and the United Kingdom.
In four trials, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last application was between 67 (flowering declining) and 79 (pods have reached typical size (green ripe); peas fully formed).

In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea plants once at a target rate of 25 g a.s./ha.
Specimens of peas and remaining plant were collected immediately after the last application from each plot, as well as 2-4, 7 and 14 days thereafter.
Specimens were analysed using BASF analytical method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.19.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in peas presented in the alpha-cypermethrin dossier were carried out in 6 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 1-3 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 2 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions-8 trials including both variants, 7 conducted in the Northern European region and one conducted in the Southern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions-4 trials conducted in the Southern European region

After one application at 12.5 g a.s./ha, initial residues in pea plant material ranged between 0.056 mg/kg and 0.825 mg/kg. Residues declined to levels between 0.037-0.361 mg/kg, 0.023–0.254 mg/kg and 0.012-0.281 mg/kg at 2-4, 7 and 14 days after application. Treated pea samples were free of residues above the limit of quantitation of the analytical method at all sampling intervals (all <0.01 mg/kg).

After two applications at 12.5 g a.s./ha, initial residues in pea plant material ranged between 0.068 mg/kg and 0.859 mg/kg. Residues declined to levels between 0.057-0.430 mg/kg, 0.028-0.346 mg/kg and 0.010-0.345 mg/kg at 2-4, 7 and 14 days after application. Treated pea samples were free of residues above the limit of quantitation of the analytical method at all sampling intervals (all <0.01 mg/kg).
After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in pea plant material ranged between 0.243 mg/kg and 1.023 mg/kg. Residues declined to levels between 0.165-0.431 mg/kg, 0.068-0.297 mg/kg and 0.071-0.259 mg/kg at 2-3, 7 and 14 days after application. Treated pea samples were free of residues above the limit of quantitation of the analytical method at all sampling intervals (all <0.01 mg/kg).

Conclusion:

In the years 2005 and 2006 a residue program on peas was conducted in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom under open field conditions.
In 8 trials supporting the proposed field GAP for the Northern European region, residues in pea plant material ranged between 0.068 mg/kg and 0.859 mg/kg at the target PHI of 0 days and between 0.057-0.430 mg/kg at the target PHI of 3±1 days. Treated pea samples were free of residues above the limit of quantitation of the analytical method at all sampling intervals (all <0.01 mg/kg).
In 4 trials supporting the proposed field GAP for the Southern European region, residues in pea plant material ranged between 0.165-0.431 mg/kg at the target PHI of 3±1 days. Treated pea samples were free of residues above the limit of quantitation of the analytical method at all sampling intervals (all <0.01 mg/kg).

2.19.2 Estimation of MRL, HR and STMR for green peas without pods

For *green peas without pods*, the following residue studies were considered (BASF DocIDs): 2006/1026856 and 2007/1007951.

The following residue values (PHI=3±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026856	<0.01 (4x)	<0.01 (2x)
2007/1007951	<0.01 (4x)	<0.01 (2x)
OECD-MRL-calculation	**0.01 (n=8, STMR=0.01, HR=0.01)**	**0.01 (n=4, STMR=0.01, HR=0.01)**

_ underlined values were used for risk assessment purposes

2.20 Asparagus

The Good Agricultural Practice (GAP) for use of BAS 310 55 I on asparagus is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at growth stage BBCH 11-93 after the harvest period of the sprouts has ended (PHI F)

The green asparagus plant parts that are treated with BAS 310 55 I do not develop before the harvest of the subterraneous sprouts has ended (BBCH 11-93). Therefore, there is no risk of residues occurring in the asparagus stems that are consumed and a MRL at the limit of quantitation of the analytical method (0.01 mg/kg) is considered appropriate.

2.21 Artichoke

Residue data from supervised trials in artichoke were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.21-1: Number of residue trials conducted per geographical region and vegetation period

Crop	Vegetation Period	Number of Trials					Report-No.
		EU North	Country	EU South	Country	Total	
Artichoke (field)	2005	-	-	2	ES, IT	2	2006/1026845

Oxspring S (2007): Study on the residue behaviour of alpha-cypermethrin in Artichoke (field) after treatment with BAS 310 40 I under field conditions in Southern Europe during 2006; BASF DocID 2007/1007948

Material and Methods:

In the years 2005 and 2006 a residue program on artichokes was conducted in the field in France (Southern European region), Greece, Italy and Spain under open field conditions.
Alpha-cypermethrin, formulated as an emulsifiable concentrate (EC 100 g a.s./L; BAS 310 40 I) was foliar applied to artichokes plants once at a target rate of 25 g a.s./ha.
The growth stage of the plants at application was between 47 (harvestable vegetative plant parts have reached 70% of final size) and 51 (inflorescence or flower buds visible).
Artichoke flower heads were collected 0, 3, 7 and 14 days after application.
Residue analysis was performed according to BASF analytical method No. 567/0 which determines total cypermethrin residues by means of HPLC-MS/MS with a LOQ of 0.01 mg/kg.
The trial data and residue results are summarized inTable 2.21.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in artichoke presented in the alpha-cypermethrin dossier were carried out in 4 different EU countries and provide data relevant to conditions in the Southern European region.
The proposed GAP is

- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days

The following residue studies were presented:

- one treatment at a target rate of 25 g a.s./ha under open field conditions-4 trials conducted in the Southern European region

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in artichoke flower heads ranged between 0.035 mg/kg and 0.060 mg/kg. Residues declined to levels between 0.019–0.060 mg/kg, 0.019-0.040 mg/kg and <0.01-0.015 mg/kg at 3, 7 and 14 days after application.

Conclusion:

In the years 2005 and 2006 a residue program on artichokes was conducted in the field in France (Southern European region), Greece, Italy and Spain under open field conditions.
In 4 trials supporting the GAP for the Southern European region, residues in artichoke flower heads ranged between 0.019-0.040 mg/kg at the target PHI of 7 days.

2.21.2 Estimation of MRL, HR and STMR for artichoke

For *artichoke*, the following residue studies were considered (BASF DocIDs): 2006/1026845 and 2007/1007948.

The following residue values (PHI=7±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]

2.22.1 Supervised residue trials in celery

Report:	**Anonymous, 2006a**
Title:	Residue behaviour of Alpha-Cypermethrin in/on fennel, curly cale, cucumbers, carrots, radies, celery, celeriac and bunshing or green onions after outdoor application of Fastac SC (SC 100) in Germany, 2005
Document No:	BASF DocID 2006/1029533
Guidelines:	EEC 91/414 Annex III (Part A Section 8), EEC 91/414 Annex II (Part A Section 6), EEC 7029/VI/95 rev. 5, EEC 7525/VI/95 rev. 7, EEC 1607/VI/97 rev. 2 10.06.1999
GLP	No, not subject to GLP regulations

Executive Summary

During the 2005 growing season two open field trials were conducted in celery in Germany to determine the magnitude of alpha-cypermethrin residues in celery after application of the formulation Fastac SC (100 g a.s./L, SC). Each field trial consisted of two plots: one control plot and one plot treated with alpha-cypermethrin. Fastac SC was applied twice at a single rate equivalent to 0.012-0.013 kg a.s./ha. The applications were made targeting 14±1 days and 7±1 days before harvest. The treated celery specimens (stalks) were taken immediately after the last application (0 DALA) and 7, 10 and 14 days thereafter.
Alpha-cypermethrin was analysed by Method No. SAA/C/PSM 023, an LC-MS/MS method with an LOQ of 0.005 mg/kg. At 7 days after the last application, alpha-cypermethrin residues were 0.1443-0.1822 mg/kg.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: Fastac SC
Lot/Batch #: Fastac SC, alpha-cypermethrin: 100 g a.s./L
Purity:
CAS#: 67375-30-8
Development code:
Spiking levels: Not reported

2. Test Commodity:

Crop: Celery
Type: Stalk vegetable
Variety: Tango
Botanical name: *Apium graveolens*
Crop parts(s) or processed Commodity: Stalks
Sample size: >1.1-1.9 kg

B. STUDY DESIGN

1. Test procedure

During the 2005 growing season two open field trials were conducted in celery in Germany to determine the magnitude of alpha-cypermethrin residues in celery after application of the formulation Fastac SC (100 g a.s./L, SC).
Each field trial consisted of two plots: one control plot and one plot treated with alpha-cypermethrin. Fastac SC was applied twice at a single rate equivalent to 0.012-0.013 kg a.s./ha. The applications were made targeting 14±1 days and 7±1 days before harvest.
0 and 7 DALA (days after last application) sampling in the untreated plot was performed. The treated celery specimens (stalks) were taken immediately after the last application (0 DALA) and 7, 10 and 14 days thereafter. Samples were stored frozen until analysis.

Table 2.22.1-1: Target application rates and timings for celery

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (g a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2005	2	2	F	Fastac SC	alpha-cypermethrin	12-13	590-640	7±1, 14±1 days before harvest

2. Description of analytical procedures

Alpha-cypermethrin was analysed by Method No. SAA/C/PSM 023. Samples were extracted with methanol/water/HCl. The final determination of alpha-cypermethrin was performed by LC-MS/MS with an LOQ of 0.005 mg/kg.

Table 2.22.1-2: Summary of recoveries for alpha-cypermethrin in celery

Matrix	Fortification Level (mg/kg)	Summary Recoveries

II. RESULTS AND DISCUSSION

Directly after the last application (0 DALA) of Fastac SC, alpha-cypermethrin residues were 0.2120-0.3381 mg/kg. At 7 days after the last application, residues were 0.1443-0.1822 mg/kg. They declined to 0.0658-0.1045 mg/kg at 14 DALA. No residues were found in the untreated specimens.
An overall summary of the residues is given in the table below.

Executive Summary

During the 2006 growing season three open field trials were conducted in celery in Germany to determine the magnitude of alpha-cypermethrin residues in celery after application of the formulation Fastac SC (100 g a.s./L, SC). Each field trial consisted of two plots: one control plot and one plot treated with alpha-cypermethrin. Fastac SC was applied twice at a single rate equivalent to 0.0125-0.014 kg a.s./ha. The applications were made targeting 14±1 days and 7±1 days before harvest. The treated celery specimens (stalks) were taken at 7 and 14 DALA.
Alpha-cypermethrin was analysed by a modification of Method No. DFG S-19, an GC-ECD method with an LOQ of 0.01 mg/kg. At 7 days after the last application, alpha-cypermethrin residues were 0.22-0.30 mg/kg.

I. MATERIAL AND METHODS

A. MATERIALS

1. **Test Material:**
   Description: Fastac SC
   Lot/Batch #: Fastac SC, alpha-cypermethrin: 100 g a.s./L
   Purity:
   CAS#: 67375-30-8
   Development code:
   Spiking levels: Not reported

2. **Test Commodity:**
   Crop: Celery
   Type: Stalk vegetable
   Variety: Tango, Utah
   Botanical name: *Apium graveolens*
   Crop parts(s) or processed Commodity: Stalks
   Sample size: ≥2.0 kg / 12 units

B. STUDY DESIGN

1. Test procedure

During the 2006 growing season three open field trials were conducted in celery in Germany to determine the magnitude of alpha-cypermethrin residues in celery after application of the formulation Fastac SC (100 g a.s./L, SC).
Each field trial consisted of two plots: one control plot and one plot treated with alpha-cypermethrin. Fastac SC was applied twice at a single rate equivalent to 0.0125-0.014 kg a.s./ha. The applications were made targeting 14±1 days and 7±1 days before harvest.
7 DALA (days after last application) sampling in the untreated plot was performed. The treated celery specimens (stalks) were taken at 7 and 14 DALA. Samples were stored frozen until analysis.

Table 2.22.1-5: Target application rates and timings for celery

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (g a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2006	3	2	F	Fastac SC	alpha-cypermethrin	12.5-14	424-640	7±1, 14±1 days before harvest

2. Description of analytical procedures

Alpha-cypermethrin was analysed by a modification of Method No. DFG S-19. Samples were extracted with acetone/water and purified with a silicagel column. The final determination of alpha-cypermethrin was performed by GC-ECD with an LOQ of 0.01 mg/kg.

Table 2.22.1-6: Summary of recoveries for alpha-cypermethrin in celery

Matrix	Fortification Level (mg/kg)	Summary Recoveries		
		n	Mean (%)	RSD (%)
DFG S-19		alpha-cypermethrin (BAS 310 I)		
celery	0.01-0.5	n r.	97	n.r.

n r. not reported

II. RESULTS AND DISCUSSION

At 7 days after the last application, alpha-cypermethrin residues were 0.22-0.30 mg/kg. They declined to 0.11-0.17 mg/kg at 14 DALA. No residues were found in the untreated specimens.
An overall summary of the residues is given in the table below.

Table 2.22.1-7: Summary of residues in celery after application of Fastac SC

2.22.2 Estimation of MRL, HR and STMR for celery

For *celery*, the following residue studies were considered (BASF DocIDs): 2006/1029533 and 2007/1035745.

The following residue values (PHI=7±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1029533	0.1443, 0.1822	-
2007/1035745	0.22,0.23,0.30	-
OECD-MRL-calculation	**0.7 (n=5, STMR=0.22, HR=0.30)**	**-**

_ underlined values were used for risk assessment purposes

2.23 Leek

Residue data from supervised trials in leek were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.23-1: Number of residue trials conducted in leek per geographical region and vegetation period

Diehl M (2007): Study on the Residue Behaviour of BAS 310 I in Leek after Treatment with BAS 310 40 I under open field Conditions in Southern and Northern Europe, 2006; BASF DocID 2007/1008498

Material and Methods:

In the years 2005 and 2006 a residue program on leek was conducted in Belgium, France (Northern and Southern European region), Germany, Italy, Spain, the Netherlands and the United Kingdom under open field conditions.

During the 2005 growing season, six field trials were conducted in leek in France (Northern and Southern European region), Germany, Italy, the Netherlands and the United Kingdom.
In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to leek plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last application was between 42 and 49 (growth complete; length and stem diameter typical for variety reached).

In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to leek plants once at a target rate of 25 g a.s./ha at growth stages between 41 (leaf bases begin to thicken or extend) and 47 (70% of the expected shaft length and diameter reached).
Specimens of leek plants without roots were collected immediately after the last application from each plot, as well as approximately 3, 7 and 14 days thereafter.
Specimens were analysed using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 2006 growing season, six field trials were conducted in leek in Belgium, France (Northern and Southern European region), Germany, Spain, and the United Kingdom.
In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to leek plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the plants at the last application was between 44 and 48. In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to leek plants once at a target rate of 25 g a.s./ha at growth stages between 45 (50% of the expected shaft diameter reached) and 47 (70% of the expected shaft length and diameter reached).
Specimens of leek plants without roots were collected immediately after the last application from each plot, as well as 2-4, 7 and 13-15 days thereafter.
Specimens were analysed using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.23.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in leek presented in the alpha-cypermethrin dossier were carried out in 7 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 2 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions-8 trials including both variants, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions-4 trials conducted in the Southern European region

After one application at 12.5 g a.s./ha, initial residues of alpha-cypermethrin in leek plants ranged between 0.018 mg/kg and 0.183 mg/kg. Residues declined to levels between 0.024–0.078 mg/kg, 0.014-0.047 mg/kg and <0.01-0.055 mg/kg at 2-4, 7 and 13-15 days after application.

After two applications at 12.5 g a.s./ha, initial residues in leek plants ranged between 0.032 mg/kg and 0.144 mg/kg. Residues declined to levels between 0.029-0.082 mg/kg, 0.018–0.071 mg/kg and <0.01-0.064 mg/kg at 2-4, 7 and 13-15 days after application.

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in leek plants ranged between 0.042 mg/kg and 0.149 mg/kg. Residues declined to levels between 0.017–0.105 mg/kg, <0.01-0.105 mg/kg and <0.01-0.054 mg/kg at 3, 7 and 14 days after application.

Conclusion:

In the years 2005 and 2006 a residue program on leek was conducted in Belgium, France (Northern and Southern European region), Germany, Italy, Spain, the Netherlands and the United Kingdom under open field conditions.
In 8 trials supporting the proposed field GAP for the Northern European region, residues in leek ranged between 0.018-0.071 mg/kg at the target PHI of 7 days.
In 4 trials supporting the proposed field GAP for the Southern European region, residues in leek ranged between 0.017-0.105 mg/kg at the target PHI of 3 days.

2.23.2 Estimation of MRL, HR and STMR for leek

For *leek*, the following residue studies were considered (BASF DocIDs): 2006/1026850 and 2007/1008498.

The following residue values (PHI=7±1 days for EU-N or PHI=3±1 days for EU-S, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026850	0.033, 0.053, 0.058, 0.071	0.062, 0.105
2007/1008498	0.018, 0.032, 0.039, 0.048	0.017, 0.032
OECD-MRL-calculation	**<u>0.15</u> (n=8, STMR=0.044, HR=0.071)**	**<u>0.2</u> (n=4, STMR=0.047, HR=0.105)**

_ underlined values were used for risk assessment purposes

2.24 Pulses (dry beans and peas)

Residue data from supervised trials in pulses (dry beans and peas) were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below.

Table 2.24-1: Number of residue trials conducted in pulses (dry beans and peas) per geographical region and vegetation period

Crop	Vegetation Period	Number of Trials					Report-No.
		EU North	Country	EU South	Country	Total	
Pulses (field)	2005	4	FR, UK	4	ES, IT	8	2006/1026858
Pulses (field)	2006	4	DE, FR, NL	4	ES, FR, GR	8	2007/1007949

Material and Methods:

In the years 2005 and 2006 a residue program in dry peas and beans was conducted in France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom.

During the 2005 growing season, eight field trials were conducted dry peas and beans in France (Northern European region), Italy, Spain and the United Kingdom.

In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea or bean plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the pea plants at the last application was between 75 (50% of pods have reached typical length; juice exudes if pressed.Tenderometer value: 105 TE) and 79 (pods have reached typical size (green ripe); peas fully formed), the beans were at stages 83 (30% of pods ripe (beans hard)) to 86 (60% of pods ripe (beans hard)).

In four trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea and bean plants once at a target rate of 25 g a.s./ha. The growth stage of the pea plants at application was between 73 (30% of pods have reached typical length; juice exudes if pressed.Tenderometer value: 80 TE) and 89 (fully ripe: all pods dry and brown. Seeds dry and hard (dry ripe)), the beans were at stages 79 (pods: individual beans easily visible) to 87 (70% of pods ripe (beans hard)).

Specimens of peas and remaining plant were collected immediately after the last application from each plot, as well as approximately 14, 21 and 28 days thereafter.

Specimens were analysed using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantification of 0.01 mg/kg in all sample materials.

During the 2006 growing season, eight field trials were conducted in dry peas and beans in France (Northern and Southern European region), Germany, Greece, Spain and the Netherlands.

In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea or bean plants on separate plots either once or twice at a target rate of 12.5 g a.s./ha. The growth stage of the pea plants at the last application was between 71 (10% of pods have reached typical length; juice exudes if pressed) and 87 (70% of pods ripe, seeds final colour, dry and hard), the beans were at stages 73 (30% of pods have reached typical length) to 81 (10% of pods ripe (beans hard) Seeds beginning to mature).

In four trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to pea and bean plants once at a target rate of 25 g a.s./ha. The growth stage of the pea plants at application was between 87 (70% of pods ripe, seeds final colour, dry and hard) and 89 (fully ripe: all pods dry and brown. Seeds dry and hard (dry ripe)), the beans were at stages 79 (pods: individual beans easily visible) to 93.

Specimens of peas and remaining plant were collected immediately after the last application from each plot, as well as 13-14, 20-22 and 27-28 days thereafter.

Specimens were analysed using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantification of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarized in Table 2.24.1-1 for dry beans and in Table 2.24.1-2 for dry peas.

_ underlined values were used for MRL calculation

Findings:

The residue studies in dry peas and beans presented in the alpha-cypermethrin dossier were carried out in 7 different EU countries and provide data relevant to conditions in the Northern and Southern European region.

The proposed GAP is

- for the Northern European region: 2 applications with 15 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 7 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray under open field conditions with a PHI of 3 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha under open field conditions – 8 trials including both variants, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions – 8 trials conducted in the Southern European region

After one application at 12.5 g a.s./ha, initial residues in pea or bean straw ranged between 0.121 mg/kg and 0.584 mg/kg. Residues in straw ranged between 0.079 – 0.310 mg/kg, 0.077 – 0.577 mg/kg and 0.050 – 0.519 mg/kg at 13-14, 20-22 and 28 days after application. Treated pea or bean seed samples were free of residues above the limit of quantification of the analytical method at all sampling intervals (all <0.01 mg/kg).

After two applications at 12.5 g a.s./ha, initial residues in pea or bean straw ranged between 0.209 mg/kg and 0.638 mg/kg. Residues in straw ranged between 0.095 – 0.459 mg/kg, 0.075 – 1.008 mg/kg and 0.101 – 0.665 mg/kg at 13-14, 20-22 and 28 days after application. Treated pea or bean seed samples were free of residues above the limit of quantification of the analytical method at all sampling intervals (all <0.01 mg/kg).

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in pea or bean straw ranged between 0.230 mg/kg and 1.503 mg/kg. Residues declined to levels between 0.095 – 0.849 mg/kg, 0.057 – 0.997 mg/kg and 0.045 – 0.505 mg/kg at 13-14, 21 and 27-28 days after application. Total residues of cypermethrin were below the LOQ (<0.01 mg/kg) in all seed specimens collected 0, 13-14, 21 and 27-28 days after application, except for specimens collected 21 and 28 days after application at Trial AF/8824/BA/4 that had residue levels of 0.022 mg/kg and 0.042 mg/kg respectively. As the treated seed samples from this trial were free of residues above the LOQ at earlier sampling intervals, this finding is most probably caused by a contamination.

Conclusion:

The residue studies presented demonstrate that dry peas or beans are free of residues above the limit of quantification of the analytical method (0.01 mg/kg).

2.24.2 Estimation of MRL, HR and STMR for pulses (dry beans and peas)

For *pulses (dry beans and peas)*, the following residue studies were considered (BASF DocIDs): 2006/1026858 and 2007/1007949.

The following residue values (PHI=14±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026858 (open field)	<0.01 (4x)	<0.01 (3x), 0.042
2007/1007949 (open field)	<0.01 (4x)	<0.01 (4x)
OECD-MRL-calculation (open field)	**0.01 (n=8, STMR=0.01, HR=0.01)**	**<u>0.06</u> (n=8, STMR=0.01, HR=0.042)**

_ underlined values were used for risk assessment purposes

2.25 Cotton

Residue data from supervised trials in cotton were used for risk assessment of alpha-cypermethrin. An overview on the studies is given below

North L (2007): Study on the residue behaviour of alpha-cypermethrin in Cotton after treatment with BAS 310 40 I under field conditions in Southern Europe during 2006; BASF DocID 2007/1007947

Material and Methods:

In the years 2004, 2005 and 2006 a residue program on cotton was conducted in Greece and Spain.

During the 2004 growing season, 2 field trials were conducted in different representative cotton growing areas in Greece and Spain to determine the residue level of alpha-cypermethrin. The soluble concentrate formulation BAS 310 41 I (SC; 100 g a.s./L) was applied once or twice to different plots of cotton plants a target application rate of 15 g a.s./ha. Specimens of plants and seeds were collected at the day of the last application as well as 6-7 and 14 days thereafter.
The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS with BASF method No. 567/0 which has a limit of quantification of 0.01 mg/kg.

During the 2005 growing season, four field trials were conducted in representative cotton growing areas in Spain and Greece.
An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L, BAS 310 40 I), was foliar applied once at a target rate of 25 g a.s./ha to cotton at growth stages between BBCH 85-87 (about 50 – 70% of bolls open). Specimens of seed and rest of plant without roots were collected immediately after application from each plot as well as 2-3, 6-7 and 13-14 days thereafter.
The specimens were analysed for total cypermethrin residues using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantification of 0.01 mg/kg in all sample materials.

During the 2006 growing season, four field trials were conducted in representative cotton growing areas in Spain and Greece.
An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L, BAS 310 40 I), was foliar applied once at a target rate of 25 g a.s./ha to cotton at growth stages up to 87.
Specimens of seed and rest of plant without roots were collected immediately after application from each plot as well as 3, 7 and 13-14 days thereafter.
The specimens were analysed for total cypermethrin residues using BASF method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS with a limit of quantification of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarized in Table 2.25.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in cotton presented in the alpha-cypermethrin dossier were carried out in 2 different EU countries and provide data relevant to conditions in the Southern European region.
The proposed GAP is

- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days

The following residue studies were presented:

- one or two treatments at a target rate of 15 g a.s./ha under open field conditions – 2 trials including both variants, conducted in the Southern European region
- one treatment at a target rate of 25 g a.s./ha under open field conditions – 8 trials conducted in the Southern European region

After one application at 15 g a.s./ha, initial residues of alpha-cypermethrin in cotton plants ranged between 0.06 mg/kg and 0.37 mg/kg. Residues in plants declined to 0.06 – 0.21 mg/kg and 0.05 – 0.07 mg/kg 6-7 and 14 days after application. In cotton seed, a residue of 0.02 mg/kg was found immediately after application in one out of two trials. All other seed samples did not show residues above the LOQ (all <0.01 mg/kg).

After two applications at 15 g a.s./ha, initial residues of alpha-cypermethrin in cotton plants ranged between 0.09 mg/kg and 0.49 mg/kg. Residues in plants declined to 0.11 – 0.32 mg/kg and 0.05 – 0.20 mg/kg 6-7 and 14 days after application. In cotton seed, no residues above the LOQ were found in one out of two trials (all <0.01 mg/kg). Seeds taken in the second trial showed initial residues of 0.04 mg/kg which declined to <0.01 mg/kg and 0.01 mg/kg, at 7 and 14 days after the last application, respectively.

After one application at 25 g a.s./ha, initial residues of alpha-cypermethrin in cotton plants ranged between 0.274 mg/kg and 1.097 mg/kg. Residues declined to levels between 0.203 – 0.942 mg/kg, 0.153 – 0.548 mg/kg and 0.078 – 0.384 mg/kg at 2-3, 6-7 and 13-14 days after application.
Initial residues in seeds ranged between <0.01 – 0.016 mg/kg and declined to <0.01 – 0.01 mg/kg at 2-3 days after application. No residues in seeds above the LOQ (0.01 mg/kg) were found at 6-7 and 13-14 days after application in 7 trials, an isolated finding of 0.018 mg/kg occurred in one trial (AF/8822/BA/2) 13 days after application.

Conclusion:

In 8 trials supporting the proposed field GAP for the Southern European region, residues in cotton plants ranged between 0.153 – 0.548 mg/kg at the target PHI of 7 ±1 days. No residues in seeds above the LOQ (0.01 mg/kg) were found 6-7 and 13-14 days after application in 7 trials, an isolated finding of 0.018 mg/kg occurred in one trial (AF/8822/BA/2) 13 days after application.

2.25.2 Estimation of MRL, HR and STMR for cotton

For *cotton*, the following residue studies were considered (BASF DocIDs): 2006/1026847 and 2007/1007947.

The following residue values (PHI=7±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Southern Europe (S-EU) [mg/kg]
2006/1026847 (open field)	<0.01 (3x), 0.018
2007/1007949 (open field)	<0.01 (4x)
OECD-MRL-calculation (open field)	**<u>0.03</u> (n=8, STMR=0.01, HR=0.018**

_ underlined values were used for risk assessment purposes

2.26 Oilseed rape

In the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414; residue studies in oilseed rape were peer-reviewed. Below, residue data from peer-reviewed trials supporting the current GAP and considered for MRL proposal and risk assessment are summarized. New trials are presented in Section M-CA 6.3.4; the MRL calculations are shown in Section M-CA 6.7. An overview on the peer-reviewed studies considered is given below.

Table 2.26-1: Number of peer-reviewed residue trials in oilseed rape considered for risk assessment per geographical region and vegetation period

BASF Agricultural Center Limburgerhof, Germany Report No. 4807
BASF RDI-No.AL-750-041
BASF DocID 2002/1004087

Material and Methods:

Five trials were carried out in the United Kingdom in 1983 in which alpha-cypermethrin was applied to oil seed rape. The compound was applied on a single occasion in each trial, as a diluted EC formulation (100 g a.s./L), at a dosage rate of 20 g a.s./ha. The growth stage of the plants at application was between 61 (10% of flowers on main raceme open, main raceme elongating) and 75 (50% of pods have reached final size).
Rape seed was harvested at 61, 69, 70, 73 or 75 days after application.
In treated seed from all trials residues of alpha-cypermethrin were found to be below the limit of determination (all <0.01 mg/kg).

Two trials in winter oilseed rape were performed in France (Southern European region) in 1992.
Alpha-cypermethrin EC 50 g a.s./L and alpha-cypermethrin PVP 50 g a.s./kg were applied to rape, on a single occasion, at dosage rates of 10 and 20 g a.s./ha.
Rapeseeds were sampled at maturity 64 or 75 days after treatment, and analysed for residues of alpha-cypermethrin.
No detectable residues were found in any of the seed samples (all <0.01 mg/kg).

Two oil seed rape decline trials were established in 2001, one in France (Southern European region) and one in Spain. Oil seed rape was treated with a 150 g a.s./kg WG alpha-cypermethrin formulation. In these decline study trials, the plants received either a single or two foliar applications at 10 g a.s./ha.
The last application was performed between growth stages BBCH 69 (end of flowering) and BBCH 77 (70% the pods have reached final size).
In the Spanish trial, whole plant specimens were collected immediately after the last application. Whole plant samples with pods removed and the removed pods were taken after 29 days. Seed specimens were sampled 42 days after application.
In the French trial, whole plant specimens were collected immediately after the last application. Whole plant samples with pods removed and removed pods were taken after 29 days. Seed specimens were sampled 43, 50 (commercial harvest), and 57 days after application.
After a single application at 10 g a.s./ha, residues in whole plant ranged between 0.07 – 0.11 mg/kg. Residues in plant without pods sampled after 29 days ranged between <0.05 – 0.11 mg/kg, in pods taken at the same time points, residues between <0.05 – 0.11 mg/kg were found. No residues above the LOQ (0.05 mg/kg) were found in any of the treated seed samples.
After two applications at 10 g a.s./ha, residues in whole plant ranged between 0.06 – 0.28 mg/kg. Residues in plant without pods sampled after 29 days ranged between <0.05 – 0.24 mg/kg, in pods taken at the same time points, residues between <0.05 – 0.36 mg/kg were found.
In the Spanish trial, a trace residue of 0.06 mg/kg was detected in seed after 42 days.
No residues above the LOQ (0.05 mg/kg) were found in any of the treated seed samples from the French trial.

2.26.2 Processing studies in oilseed rape

Within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 this processing study in oilseed rape (BASF RDI-No. AL-750-038) was submitted. The study was assessed as not being required (3rd Addendum to the Monograph: Addendum Chapter B-7 (Residue data), January 2003). Therefore, a review was not performed at this time. The study was not included in the application as it had been submitted already with the alpha-cypermethrin addendum dossier. Below it is summarized for the reviewer´s convenience.

Report:
Grolleau G. 2001b
Alphacypermethrin (AC 900049) 150 g a.s./kg WG (RLM 11203): At harvest residue study on alphacypermethrin in oil seed rape and oil, South France, 2000
BASF RDI-No.: AL-750-038
BASF DocID 2001/7001649

Guidelines: EEC 91/414 Annex II 6,EEC 91/414 Annex III 8,EEC 96/68,EEC 7029/VI/95 rev. 5,EEC 1999/11/EC,Decret No. 98-1312 (31-12-1998)

GLP: yes
(certified by Groupe Interministeriel des Produits Chimiques, France)

Materials and Methods:

In 2000, two oilseed rape (OSR) residue trials were established in Southern France. OSR [variety: Expert (trial 00-602-649) and variety: Bristol (00-602-65)] was treated with the 150 g a.s./kg WG (RLM 11203) alpha-cypermethrin formulation. In each of these two residue trials, OSR received either a single 10 g a.s./ha or a single 100 g a.s./ha foliar application 50 days prior to typical commercial harvest. In separate plots, OSR also received three 10 g a.s./ha or three 100 g a.s./ha foliar applications 79, 59, and 50 days prior to typical commercial harvest.

Actual applications were within 10% of nominal, ranging from 9.5 g a.s./ha to 10.6 g a.s./ha (10 g a.s./ha) or 94 g a.s./ha to 98 g a.s./ha (100 g a.s./ha). The single applications occurred at the BBCH 67 (flowering declining, majority of the petals fallen) growth stage. The last of the three applications also occurred at BBCH 67. Application volumes ranged from 374 L/ha to 405 L/ha. Oil seed rape specimens [seeds after harvester thrashing] were sampled at typical commercial harvest, between BBCH 89 - 92 (00-602-649) and at BBCH 92 (00-602-650).

Field samples for residue analysis from both trials were frozen within 24 hours of sampling and remained frozen (including during transportation) until analysis. These specimens were shipped frozen to BASF Agro Research, BASF plc, Unit 60, 156 Fareham Road, Gosport, Hampshire, PO13 0AU, UK, where they were stored until shipment to the analytical laboratory.

Bulk OSR samples from the 1 x 100 g a.s./ha and the 3 x 100 g a.s./ha plots from both trials (00-602-649 and 00-602-650), sufficient for processing, were shipped unfrozen to the processor [Viticulture Recherhhe et Developpement (VITI R & D).

The processing phase was conducted at VITI R&D, 101 impasse des Capitelles, VILLETELLE, France, according to VITI R&D Processing Phase Plan GRA 0006 EUR.

Specimen analysis was conducted at CEM Analytical Services Ltd. (CEMAS), Glendale Park, Fernbank Road, North Ascot, Berkshire, UK. OSR seeds were ground prior to analysis while all other specimen were homogenized with dry ice. The OSR specimens were analyzed using BASF Agro Research analytical method RLA 12594.02V entitled:

"Analysis of Alphacypermethrin (AC 900049) in Olives and Olive Oil."

A method performance check was included with study AL-GE-00-999 (CEMR-1429) and validated the 0.05 mg/kg alpha-cypermethrin LOQ in OSR substrates.

Concurrent procedural recoveries at the LOQ [0.05 mg/kg in seeds, crude oil, and press cake)] and 10 times the LOQ [in seeds, refined oil, and press cake] were within the acceptable range of 70% to 110%.

Findings:

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any untreated harvest seed specimens.

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any harvest OSR seeds taken 50 days after the single 10 g a.s./ha or the last of the three 10 g a.s./ha applications from either trial (00-602-649 or 00-602-650). Alpha-cypermethrin residues ranged from <0.05 mg/kg (00-602-649) to 0.07 mg/kg (00-602-650) in harvest OSR seeds taken 50 days after the single 100 g a.s./ha application; from 0.07 mg/kg (00-602-650) to 0.10 mg/kg (00-602-649) in harvest OSR seeds taken 50 days after the third 100 g a.s./ha application.

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any untreated OSR processed fractions (press cake, crude oil, and refined oil).

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any OSR processed fraction (press cake, crude oil, and refined oil) resulting from seed taken 50 days after the single 100g a.s./ha or the last of three 100 g a.s./ha applications.

Figure 2.26.2-1: OSR Processing procedure flowchart - DocID AL-750-038

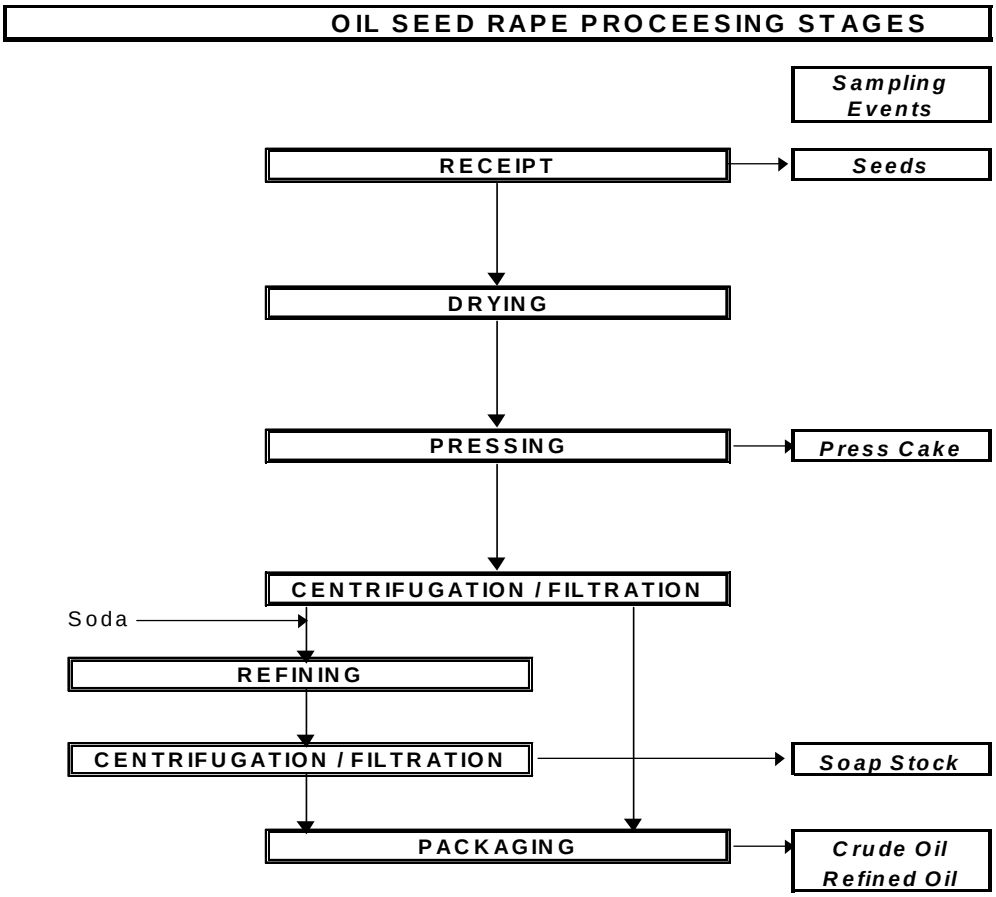

Table 2.26.2-1: Mass balance of OSR processing - DocID AL-750-038

	00-602-649			00-602-650		
Process Step	U1	T11	T21	U2	T12	T22
Seed prior to cleaning (kg)	5.75	7.55	6.30	5.55	6.70	7.00

Loss on cleaning (%)	15	3	3	1	1	1
Seed prior to drying (kg)	4.90	7.30	6.10	5.50	6.60	6.90
Seed after drying (kg)	4.50	6.70	5.60	5.00	6.00	6.50
Loss on drying (%)	8	8	8	9	10	6
Seed to pressing (kg)	4.50	6.70	5.60	5.00	6.00	6.50
Press cake (kg)	2.90	4.25	3.55	3.20	3.75	3.90
Crude oil (g)	1540	2340	1900	1860	2150	2370
Accountability (%) (1)	99	98	97	101	98	96
Accountability (%) (2)	77	87	87	91	88	90
Crude oil (g)	1540	2340	1900	1860	2150	2370
Filtered crude oil (g)	1480	2230	1800	1798	2058	2300
Centrifuged/filtered crude oil (g)	1366	2142	1748	1690	1943	2201
Accountability (%) (3)	88	92	92	91	90	93
Crude oil to refining (mL)	800	800	800	800	800	800
Filtered refined oil (mL)	720	710	710	750	750	750
Centrifuged/filtered refined oil (mL)	685	665	660	605	655	630
Accountability (%) (4)	86	83	83	76	82	79
U1 and U2 are the control OSR seeds from trial 00-602-649 and 00-602-650, respectively.						
T11 and T12 are the OSR seeds from from the 00-602-649 1 x 100 g a.s./ha and 3 x 100 g a.s./ha applications, respectively						
T12 and T22 are the OSR seeds from from the 00-602-650 1 x 100 g a.s./ha and 3 x 100 g a.s./ha applications, respectively						
all percentages are rounded to the nearest whole number						
accountability (%) (1) = pressing efficiency = [press cake weight + crude oil weight/seed to pressing] x 100						
accountability (%) (2) = [press cake weight + crude oil weight/beginning seed weight] x 100						
accountability (%) (3) = [centrifuged/filtered crude oil weight/initial crude oil weight] x 100						
accountability (%) (4) = [centrifuged/filtered refined oil volume/initial crude oil volume to refining] x 100						

On average, approximately 55% of the initial seed weight (before cleaning and drying) is accounted for in the press cake and approximately 29% is accounted for in the centrifuged/filtered crude oil.

Based on the alpha-cypermethrin residue (ranging from < 0.05 mg/kg to 0.07 mg/kg) found in the OSR seed treated at an exaggerated rate (1 x 100 g a.s./ha), there would be no reasonable expectation of alpha-cypermethrin residue above the method LOQ (0.05 mg/kg) in any processed fraction (press cake, crude oil, refined oil). The results of this processing study support this conclusion.

Table 2.26.2-2: Transfer factors of OSR processing - DocID AL-750-038

Within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 this processing study in oilseed rape (BASF RDI-No. AL-750-042) was submitted. The study was assessed as not being required (3rd Addendum to the Monograph: Addendum Chapter B-7 (Residue data), January 2003). Therefore, a review was not performed at this time. The study was not included in the application as it had been submitted already with the alpha-cypermethrin addendum dossier. Below it is summarized for the reviewer´s convenience.

Report:	Trewhitt J. and Zimmermann U. 2002b Processing study on the residue behavior of alphacypermethrin in oil seed rape after application of BAS 310 08 I under field conditions in France (S), 2001. BASF RDI No.: AL-750-042 BASF DocID 2002/7005182
Guidelines:	EEC 91/414 Annex II (Part A Section 6),EEC 91/414 Annex III (Part A Section 8),EEC 1607/VI/97 rev. 2 10.06.1999,EEC 7029/VI/95 rev. 5,EEC 7525/VI/95 rev. 2
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Materials and Methods:

In 2001, two winter oilseed rape (OSR) residue trials were established in southern France. OSR [variety: Elite (FBD/07/01) and variety: Cheyenne (FTL/08/01)] was treated with the 150 g a.s./kg WG (RLM 11203) alpha-cypermethrin formulation. In each of these two residue trials, OSR received two 100 g a.s./ha foliar applications 63 days (FTL/08/01)/64 days (FBD/07/01) and 49 days (FTL/08/01)/50 days (FBD/07/01) prior to typical commercial harvest.

Actual applications were within 10% of nominal, ranging from 99 g a.s./ha to 109 g a.s./ha. In both trials, the last applications occurred at the BBCH 71 (10% of pods have reached final size). Application volumes ranged from 298 L/ha to 327 L/ha. Oil seed rape specimens (seeds) were sampled at typical commercial harvest BBCH 89 (fully ripe: nearly all pods ripe, seeds black and hard).

Field samples for residue analysis from both trials were frozen within 24 hours of sampling and remained frozen (including during transportation) until analysis. These specimens were shipped frozen to BASF Akteingesellschaft, BASF Agricultural Center Limburgerhof, Crop Protection Division, Limburgerhof, Germany, where they were stored until shipment to the analytical laboratory.

Bulk OSR samples from both trials, sufficient for processing, were shipped unfrozen to the processor [Viticulture Recherche et Developpement (VITI R & D).

The processing phase was conducted at VITI R&D, 101 impasse des Capitelles, VILLETELLE, France.

Specimen analysis was conducted at the BASF Agricultural Research Center, Limburgerhof, Germany. The OSR specimens were analyzed using BASF method 989/0 (BASF Agro Research analytical method RLA 12594.02V) entitled:

"Analysis of Alphacypermethrin (AC 900049) in Olives and Olive Oil."

A method performance check was included with study AL-GE-00-999 (CEMR-1429) and validated the 0.05 mg/kg alpha-cypermethrin LOQ in OSR substrates.

Concurrent procedural recoveries at the LOQ (0.05 mg/kg) and 10 times the LOQ in seeds, refined oil, and press cake were reasonable given the complexity of the matrices, but not always within the 70% to 110% range.

Findings:

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in any untreated harvest seed specimens.

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in the press cake from untreated OSR seeds. Apparent alpha-cypermethrin residues were found in both the crude oil [and the refined oil [0.05 mg/kg (FBD/07/01) and 0.05 mg/kg (FTL/08/01)] from untreated OSR seeds.

Detectable alpha-cypermethrin residues were found in the treated OSR seeds from both trials [0.07 mg/kg (FBD/07/01) and 0.16 mg/kg (FTL/08/01)].

No detectable alpha-cypermethrin residues were found above the validated method LOQ (0.05 mg/kg) in the press cake from OSR seeds receiving two 100 g a.s./ha and sampled at typical commercial harvest (49 DAT2/50 DAT2; BBCH 89).

Detectable alpha-cypermethrin residues were found in both the crude oil [0.11 mg/kg (FBD/07/01) and 0.13 mg/kg (FTL/08/01)] and refined oil [0.09 mg/kg (FBD/07/01) and 0.16 mg/kg (FTL/08/01)] from OSR seeds receiving two applications 100 g a.s./ha and sampled at typical commercial harvest (49 DAT2/50 DAT2; BBCH 89).

Table 2.26.2-3: OSR processing procedure flowchart - DocID AL-750-042

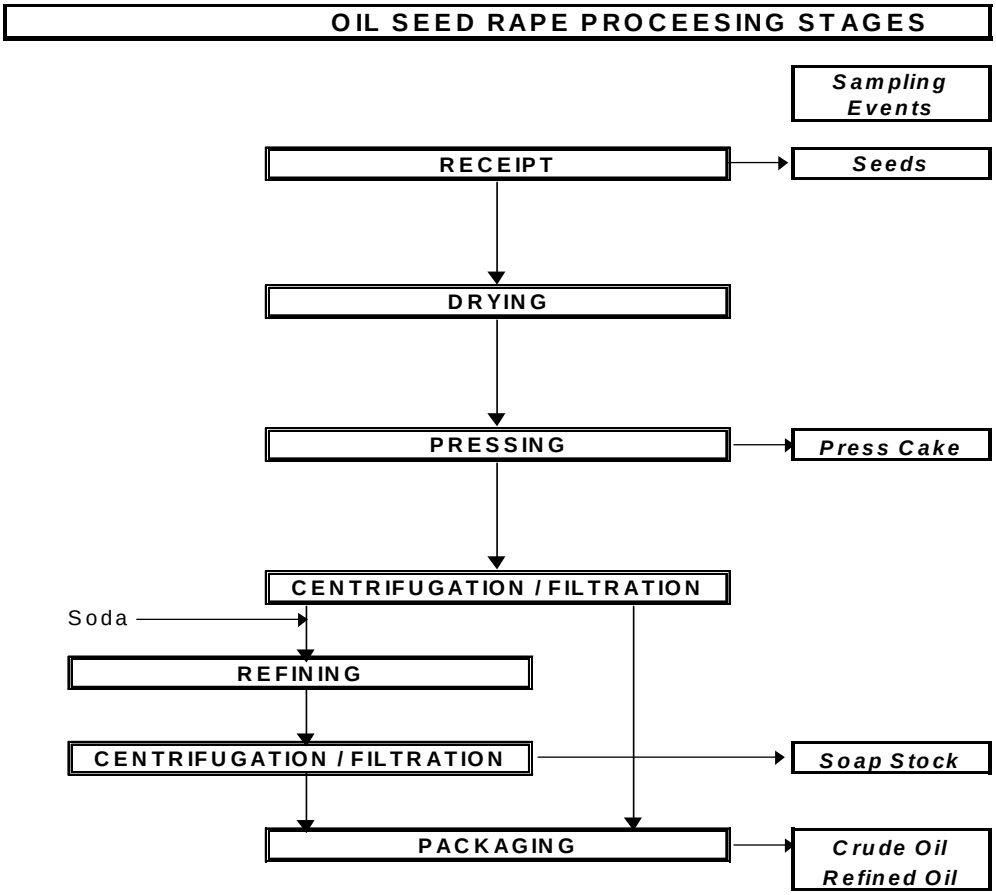

Table 2.26.2-4: Mass balance of OSR processing - DocID AL-750-042

	FBD/07/01		FTL/08/01	
Process Step	**Untreated**	**Treated**	**Untreated**	**Treated**
Seed to pressing (kg)	6.15	6.05	6.10	5.85
Press cake (kg)	3.10	2.95	3.35	3.10
Crude oil (g)	1457	1579	1702	1879
Accountability (%) (1)	74	75	83	85
Crude oil to refining (g)	715	711	713	721
Centrifuged/filtered refined oil (g)	547	540	542	556
Accountability (%) (2)	77	76	76	77
Untreated = the control OSR seeds from each trial.				
Treated = OSR seeds from each trial treated twice at 100 g a.s./ha.				
all percentages are rounded to the nearest whole number				
accountability (%) (1) = pressing efficiency = [press cake weight + crude oil weight/seed to pressing] x 100				
accountability (%) (2) = [centrifuged/filtered refined oil weight/initial crude oil weight to refining] x 100				

Based on the alpha-cypermethrin residue (ranging from < 0.05 mg/kg to 0.07 mg/kg) found in the OSR seed treated at an exaggerated rate (1 x 100 g a.s./ha), there would be no reasonable expectation of alpha-cypermethrin residue above the method LOQ (0.05 mg/kg) in any processed fraction (press cake, crude oil, refined oil). The results of this processing study support this conclusion.

Table 2.26.2-5: Transfer Factors of OSR processing - DocID AL-750-042

2.27 Barley

2.27.1 Supervised residue trials in barley

In the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414; residue studies in barley were peer-reviewed. Below, residue data from peer-reviewed trials supporting the current GAP and considered for MRL proposal and risk assessment are summarized. New trials are presented in Section M-CA 6.3.5; the MRL calculations are shown in Section M-CA 6.7. An overview on the peer-reviewed studies considered is given below.

Full study reference
Carlon R. (2007): Residues of Alpha-cypermethrin in cereals from France treated with Fastac PVP – 1992 trials
BASF RDI-No.AL-730-029

Material and Methods:

One trial in spring barley was performed in France (Southern European region) during the year 1992. Two different formulation of aplha-cypermethrin, a 50 g a.s./L EC and a 50 g a.s./kg PVP, were applied once to separate plots each at rates of 15 and 30 g a.s./ha. Samples of grain and straw were taken 48 days after application. Residues in straw ranged between 0.05 – 0.10 mg/kg. No residues above the LOQ (0.010 mg/kg) were found in treated grain samples.

The trial data and residue results are summarized in Table 2.27.1-2.

2.28.1 Supervised residue trials in maize

Report:	**Oxspring S., 2010c**
Title:	Study on the behaviour of alpha-cypermethrin in maize after treatment with BAS 310 40 I in Northern and Southern Europe during 2009
Document No:	BASF DocID 2009/1125196
Guidelines:	EEC 91/414 (1607/VI/97), EEC 91/414 Annex II (Part A Section 6), EEC 91/414 Annex III (Part A Section 8), EEC 7029/VI/95 rev. 5, EEC 7525/VI/95 rev. 7, EU Directive 96/68/EC
GLP	Yes

Executive Summary

During the growing season of 2009, a total of three trials were conducted in representative maize growing areas in Germany, France and Spain, to determine the magnitude and decline of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC).
Therefore BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g/L) was applied twice or once to the treated plot at a rate equivalent to 0.0150 kg a.s./ha or 0.0300 kg a.s./ha. In all trials the applications were made at crop stages BBCH 83 and 87.
For the analysis samples of maize were taken directly after the last application (0 DALA) and at 7±1, 14±1, 21±1 and 32±1 DALA, where specimens of cobs without husks, rest of plant with husks, grain and rest of plant without roots were taken.
The maize specimens were analysed for alpha-cypermethrin according to BASF Method No. 567/0, which determines the analytes by means of LC-MS/MS with a limit of quantitation (LOQ) of 0.01 mg/kg.
In all trials, residues of alpha-cypermethrin (BAS 310 I) in treated maze grain and cobs were not detectable. The treated maize whole plant specimens collected directly after the last application (0 DALA) of BAS 310 40 I contained a residue of 0.177-0.290 mg/kg. Residues in maize rest of plant ranged from 0.118-0.318 mg/kg.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 40 I
Lot/Batch #: 1209 (BAS 310 40 I, 100 g/L alpha-cypermethrin)
Purity:
CAS#: 52315-07-8 (alpha-cypermethrin)
Development code:
Spiking levels: 0.01-1.0 mg/kg

2. Test Commodity:

Crop: Maize
Type: Cereals
Variety: Bredao, Zidane, Sancia
Botanical name: *Zea mays*
Crop parts(s) or processed
Commodity: Whole plant w/o roots, cobs, rest of plant, grain
Sample size: 1.0 kg

B. STUDY DESIGN

1. Test procedure

During the growing season of 2009, a total of three trials were conducted in representative maize growing areas in Germany, France and Spain, to determine the magnitude and decline of residues of BAS 310 I (alpha-cypermethrin) in or on raw agricultural commodities (RAC).
Each field trial consisted of two plots, one control plot (plot 1) and one plot treated with BAS 310 40 I (plot 2).
In two of three trials (L090227 and L090228) BAS 310 40 I was applied twice at a rate equivalent to 0.015 kg alpha-cypermethrin/ha and for the other trial (L090229) the application was made once at a rate equivalent to 0.0300 kg alpha-cypermethrin/ha. The applications took place at BBCH 83-87 with an application rate of 200 L/ha.
For the analysis samples of maize were taken directly after the last application (0 DALA) and at 7±1, 14±1, 21±1 and 32±1 DALA, where specimens of cobs without husks, rest of plant with husks, grain and rest of plant w/o roots were taken.

Table 2.28.1-1: Target application rates and timings for maize

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2009	3	2	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0150	200	1st appl.: 83-87 BBCH 2nd appl.: 85-87 BBCH
		1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0300	200	1st appl.: 83-85 BBCH

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin).

The residues of alpha-cypermethrin in maize specimens were extracted from plant matrices using a mixture of methanol/water/hydrochloric acid. A liquid/liquid partition against cyclohexane was used for clean up. The final determination of alpha-cypermethrin was performed by LC-MS/MS. The limit of quantitation (LOQ) of the method is 0.01 mg/kg. The mean procedural recovery averaged 79±9% for alpha-cypermethrin at fortification levels of 0.01 mg/kg and 1.0 mg/kg.

Table 2.28.1-2: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in maize

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
whole plant w/o root	0.01-0.5	12	77	11	14
rest of plant	0.01-1.0	4	81	11	13
grain	0.01-0.1	8	82	5	6
cobs	0.01-0.1	4	76	3	4

II. RESULTS AND DISCUSSION

Directly after the last application (0 DALA) of BAS 310 40 I, alpha-cypermethrin residues ranged between 0.177-0.290 mg/kg in whole plant specimens. At 7±1 days after the last application residues were 0.189-0.318 mg/kg in rest of plant and <0.01 mg/kg in maize cobs and grain respectively. At 14±1 DALA, residues were 0.137-0.266 mg/kg in rest of plant and <0.01 mg/kg in cobs and grain respectively. After a longer PHI (20-33 DALA) residues in maize rest of plant ranged between 0.118-0.182 mg/kg.

An overall summary of the residues is given in the table below.

Table 2.28.1-3: Summary of residues of BAS 310 I in maize from trials according to critical GAP after application of BAS 310 51 I and BAS 310 40 I

Crop	Year	No. of Appl.	Application	DALA	BBCH	Residues Found (mg/kg)

				14	89	grain	0.214
				20-21	88-89	grain	0.134-0.182
				32	89	grain	0.134

DALA = days after last application
BBCH = growth stage at respective sampling
* = without roots

III. CONCLUSION

Directly after the last application (0 DALA) of BAS 310 40 I, alpha-cypermethrin residues ranged between 0.177-0.290 mg/kg in whole plant specimens. At 14±1 DALA, the residues of alpha-cypermethrin found in rest of plant were 0.137-0.266 mg/kg and <0.01 mg/kg in grain. In all trials, residues of alpha-cypermethrin in treated maize grain and cobs were not detectable.

Material and Methods:

In the years 1981-1990 a field program on maize was conducted in France (Northern and Southern European region), Germany, South Africa and Brazil to investigate the residue behaviour of alpha-cypermethrin.

During the 1981 growing season, two field trials were conducted in maize in France (Northern and Southern European region). An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L; WL 85871 100 g a.s./L EC) was foliar applied to maize plants on two different plots in each trial. In one variant, one treatment was done at a target rate of 30 g a.s./ha. In the second variant, a single treatment at a target rate of 50 g a.s./ha was applied. The application took place at a plant height between 0.85–1.3 m. Specimens of maize plant and grain were collected 65, 95 and 100 days after application.
The specimens were analysed for alpha-cypermethrin by means of GC-ECD with method No. SAMS 233-1 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 1989 growing season, two field trials were conducted in maize in France (Southern European region). An emulsifiable concentrate formulation of alpha-cypermethrin (50 g a.s./L; FASTAC® 50 g a.s./L EC) was foliar applied to maize plants twice at a target rate of 30 g a.s./ha. The last application took place at the beginning drying of the plants. Specimens of silage and grain were collected 13, 29, 42 and 50 days after the last application.
The specimens were analysed for alpha-cypermethrin by means of GC-ECD with method No. SAMS 383-1 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 1990 growing season, three field trials were conducted in maize in France (Southern European region). An emulsifiable concentrate formulation of alpha-cypermethrin (50 g a.s./L; FASTAC® 50 g a.s./L EC) was foliar applied to maize plants twice at a target rate of 40 g a.s./ha. The last application took place between flowering and ripening of cobs. Specimens of grain were collected 13, 22 and 40 days after the last application.
The specimens were analysed for alpha-cypermethrin by means of GC-ECD with method No. SAMS 351-1 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 1986 growing season, four field trials were conducted in maize in Germany. A suspension concentrate formulation of alpha-cypermethrin (SC 100 g a.s./L) was foliar applied to maize plants once at a target rate of 17.5 g a.s./ha. The application took place approximately two months before harvest. Specimens of grain were collected 0, 7, 14, 21 days (plant) and 57-62 days (cobs and straw) after application.
The specimens were analysed for alpha-cypermethrin by means of GC-ECD with method No. SAMS 383-1 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 1987 growing season, four field trials were conducted in maize in Germany. A suspension concentrate formulation of alpha-cypermethrin (SC 100 g a.s./L) was foliar applied to maize plants once at a target rate of 17.5 g a.s./ha. The application took place at growth stage 57 (tassel emergence). Specimens of grain were collected 0, 7, 14, 21 days (plant) and 56-69 days (grain) after application.
The specimens were analysed for alpha-cypermethrin by means of GC-ECD with method No. SAMS 351-1 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

One trial was performed in maize during the growing season 1982 in South Africa. An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L; WL 85871 100 g a.s./L EC) was foliar applied to maize plants once at a target rate of 30 g a.s./ha. Specimens of maize grain were collected 0, 2, 7 and 14 days after application.
The specimens were analysed for alpha-cypermethrin by means of GC-ECD with method No. SAMS 351-1 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

During the 1983 growing season, one field trial was conducted in maize in Brazil. An emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L; WL 85871 100 g a.s./L EC) was foliar applied to maize plants on two different plots in each trial. In one variant, two treatments were done at a target rate of 12 g a.s./ha. In the second variant, two treatments at a target rate of 24 g a.s./ha were applied. The last application took place at ripening of the cobs. Specimens of maize grain were collected 22 days after the last application.
The specimens were analysed for alpha-cypermethrin by means of GC-ECD with method No. SAMS 351-1 which has a limit of quantitation of 0.01 mg/kg in all sample materials.

The trial data and residue results are summarised in Table 2.28.1-6.

_ underlined values were used for MRL determination

Findings:

The residue studies in maize presented in the alpha-cypermethrin dossier were carried out in 4 different EU and Non-EU countries and provide data relevant to conditions in the Northern and Southern European region.

The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 14 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 14 days

The following residue studies were presented:

- one treatment at a target rate of either 30 or 50 g a.s./ha-2 trials including both variants, one conducted in the Northern European Region and one conducted in the Southern European Region
- one treatment at a target rate of 30 g a.s./ha-one trial conducted in South Africa
- two treatments at a target rate of 30 g a.s./ha-2 trials, both conducted in the Southern European Region
- two treatments at a target rate of 40 g a.s./ha-3 trials, all conducted in the Southern European Region
- one treatment at a target rate of 17.5 g a.s./ha-8 trials, all conducted in the Northern European Region
- two treatments at a target rate of either 12 or 24 g a.s./ha-one trial conducted in Brazil

Two trials were performed in the year 1981 in France with a single treatment at a target rate of either 30 or 50 g a.s./ha. No residues above the limit of quantitation (LOQ; 0.01 mg/kg) were found in treated maize plant samples collected 65 or 95 days after application. Mature grain specimens collected 95 or 100 days after application were free of residues above the LOQ (all <0.01 mg/kg).

One trial was performed in South Africa in the year 1982 with a single application at a target rate of 30 g a.s./ha. Immediately after application, a residue at the LOQ (0.01 mg/kg) was found in treated maize grain. No residues above the LOQ were found at later sampling points 2, 7 and 14 days after application.

Two trials were performed in the year 1989 in France with two applications at a target rate of 30 g a.s./ha. Residues in silage ranged between 0.19 mg/kg at 29 days after the last application and 0.32 mg/kg at 13 days after the last application. Residues in grain were below the LOQ of the analytical method 42 and 50 days after the last application, respectively (<0.01 mg/kg).

Three trials were performed in the year 1990 in France with two applications at a target rate of 40 g a.s./ha. No residues above the LOQ of the analytical method (0.01 mg/kg) were found in treated maize grain samples collected 13, 22 or 40 days after the last application.

Eight trials were performed in the years 1986 and 1987 in Germany with a single treatment at 17.5 g a.s./ha. Residues in plant material immediately after application ranged between 0.02–1.74 mg/kg and declined to 0.01-0.86 mg/kg, 0.01-0.46 mg/kg and 0.02-0.34 mg/kg at 7, 14 and 21 days thereafter.
In the 1986 trials, cob and straw samples were collected 57-62 days after application. In the 1987 trials, grain samples were taken 56-69 days after application. All treated samples of whole cobs or maize grain were free of residues above the LOQ of the analytical methods used (0.01 mg/kg) in all trials. In straw, residues between 0.08-0.23 mg/kg were found.

One trial was performed in the year 1983 in Brazil with two treatments at a target rate of either 12 or 24 g a.s./ha. No residues above the limit of quantitation (LOQ; 0.01 mg/kg) were found in treated maize grain samples collected 22 days after the last application.

Conclusion:

17 residue trials in maize are presented which demonstrate the absence of residues in maize grain. Even after two applications at 40 g a.s./ha, which is considerably higher than the proposed GAP, no residues were found in maize grain. This is due to the fact that alpha-cypermethrin is a non-systemic compound and therefore not translocated in the plant. Residues can only arise from direct contact with the spray. Maize cobs are protected from the spray by the hull leaves which prevent contamination of the kernels. No residues are to be expected in the grain, a situation which is confirmed by the residue studies presented.

2.28.2 Estimation of MRL, HR and STMR for maize

For *maize*, the following residue studies were considered (BASF DocIDs): 2009/1125196, AL-730-013, AL-730-057, AL-730-058, AL-730-059, AL-730-060, AL-730-062, AL-730-063, AL-730-064, AL-730-065, AL-730-013, AL-730-019 and AL-730-027.

The following residue values (PHI=13-100 days) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2009/1125196	<0.01 (2x)	<0.01

Full study reference

North L (2007): Study on the residue behaviour of BAS 310 I in Rice after treatment with BAS 310 40 I under field conditions in Southern Europe during 2005; BASF DocID 2006/1026848

North L (2007)

Full study reference

North L (2007): Study on the residue behaviour of alpha-cypermethrin in Rice after treatment with BAS 310 40 I under field conditions in Southern Europe during 2006; BASF DocID 2007/1007946

Material and Methods:

During the 2005 and 2006 growing seasons, eight field trials in rice were conducted in representative rice growing areas in France (Southern European region), Spain, Italy and Greece.

BAS 310 40 I, an emulsifiable concentrate formulation of alpha-cypermethrin (100 g a.s./L), was foliar applied either once or twice to separate plots of rice at a rate of 12.5 g a.s./ha. The growth stage of the plants at the last application was between 65 (full flowering: anthers visible on most spikelets) and 87 (hard dough: grain content solid, fingernail impression held).
Rice plant (without root) specimens were collected immediately after the last application. Panicles and the rest of plant (without root) were collected 13–15 days after the last application. Rice grain and straw specimens were collected at 20-22 and 27–29 days after the last application.
The specimens were analysed using BASF method no. 567/0 which quantifies the residues of underivatised cypermethrin by means of HPLC-MS/MS with a limit of quantitation of 0.01 mg/kg in all sample materials

The trial data and residue results are summarised in Table 2.29.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue studies in rice presented in the alpha-cypermethrin dossier were carried out in 4 different countries and provide data relevant to conditions in the Southern European region.

The proposed GAP is

- for the Southern European region: 1-2 applications with 12.5 g a.s./ha applied at infestation as an overall spray with a PHI of 21 days

The following residue studies were presented:

- one or two treatments at a target rate of 12.5 g a.s./ha-8 trials including both variants, all conducted in the Southern European Region

During the 2005 and 2006 growing seasons, eight field trials were conducted in representative rice growing areas in France (Southern European region), Spain, Italy and Greece.

After one application at 12.5 g a.s./ha, total residues of cypermethrin were 0.063-0.511 mg/kg in rice plant specimens collected immediately after the last application. Total residues were 0.028-0.160 mg/kg and 0.015-0.134 mg/kg, respectively, in rice panicles and the rest of the plant taken 13–15 days after the last application. Total residues were 0.015–0.176 mg/kg and 0.044–0.349 mg/kg, respectively, in grain and straw specimens collected 20-22 days after the last application and 0.020–0.206 mg/kg and 0.021–0.330 mg/kg, respectively, in grain and straw collected after 27–29 days.
After two applications at 12.5 g a.s./ha, total residues of cypermethrin were 0.291–0.590 mg/kg in rice plant specimens collected immediately after the last application. Total residues were 0.092–0.357 mg/kg and 0.086–0.194 mg/kg, respectively, in rice panicles and the rest of the plant taken 13–15 days after the last application. Total residues were <0.01–0.205 mg/kg and 0.065–0.354 mg/kg, respectively, in grain and straw specimens collected 20-22 days after the last application and 0.011–0.151 mg/kg and 0.061–0.351 mg/kg, respectively, in grain and straw collected after 27–29 days.

Conclusion:

During the 2005 and 2006 growing seasons, eight field trials in rice were conducted in representative rice growing areas in France (Southern European region), Spain, Italy and Greece.
In 8 trials supporting the GAP for the Southern European region, total residues were <0.01–0.205 mg/kg and 0.065–0.354 mg/kg, respectively, in grain and straw specimens collected 20-22 days after the last application.

2.29.2 Estimation of MRL, HR and STMR for rice

For *rice*, the following residue studies were considered (BASF DocIDs): 2006/1026848 and 2007/1007946.

The following residue values (PHI=14-21±1 days, or later if higher residue values occurred) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2006/1026848	-	0.011, 0.039, 0.148, 0.206
2007/1007946	-	0,066, 0.073, 0.11, 0.13,
OECD-MRL-calculation	**-**	**<u>0.4</u> (n=8, STMR=0.092, HR=0.206)**

_ underlined values were used for risk assessment purposes

2.30 Wheat

2.30.1 Supervised residue trials in wheat

In the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414; residue studies in wheat were peer-reviewed. Below, residue data from peer-reviewed trials supporting the current GAP and considered for MRL proposal and risk assessment are summarized. New trials are presented in Section M-CA 6.3.6; the MRL calculations are shown in Section M-CA 6.7. An overview on the peer-reviewed studies considered is given below.

Table 2.30.1-1: Number of peer-reviewed residue trials in wheat considered for risk assessment per geographical region and vegetation period

Carlon R. (1992): Residues of Alpha-cypermethrin in wheat from Germany treated with Fastac PVP – 1992 trials
BASF RDI-No.AL-730-031

Materials and methods:

Three trials were performed in France (Northern and Southern European region) during the year 1983. Alpha-cypermethrin 100 g a.s./L EC was sprayed on wheat, on a single occasion, diluted with water at a dosage rate of 17.5 g a.s./ha.
Wheat was sampled nearly 38 – 46 days after treatment and analysed for residues of alpha-cypermethrin. No detectable residues were found in any of the grain samples (LOQ 0.01 mg/kg) while residues in straw ranged between 0.17 and 0.44 mg/kg.

Eight trials were performed in France (Northern and Southern European region) in the year 1984.
Alpha-cypermethrin 50 g a.s./L EC was sprayed on wheat, on a single occasion, diluted with water at a concentration in spray of 3 g a.s./hL, corresponding to a dosage rate of 15 g a.s./ha.

Wheat grain and straw was sampled at intervals up to 10 weeks after treatment and analysed for residues of alpha-cypermethrin.
Results showed that in grain no detectable residues were found in any of the samples (all <0.01 mg/kg).
In straw, on average, residues declined from 0.5 mg/kg immediately after treatment to 0.15 mg/kg after 2 weeks and below 0.1 mg/kg at harvest (PHI 6 to 10 weeks).

Three trials in wheat were performed in France (Southern European region) during the year 1992.
Alpha-cypermethrin EC 50 g a.s./L and alpha-cypermethrin PVP 50 g a.s./kg were applied to wheat, on a single occasion, at dosage rates of 15 and 30 g a.s./ha.
Straw and grain were sampled at maturity, 38 - 50 days after treatment and analysed for residues of alpha-cypermethrin.
No detectable residues were found in any of the grain samples (all <0.01 mg/kg).
Residue levels in straw after application of 15 g a.s./ha ranged between 0.02 – 0.75 mg/kg with the EC formulation and between 0.05 – 0.60 mg/kg with the PVP formulation.
One trial in wheat was performed during the year 1992 in Germany. Alpha-cypermethrin EC (100 g a.s./l and alpha-cypermethrin PVP 150 g a.s./kg were applied to wheat, on a single occasion, each formulation at a dosage rate of 15 g a.s./ha. Straw and grain samples were taken at maturity, 34 days after treatment, and analysed for residues of alpha-cypermethrin.
No detectable residues were found in any of the grain samples from both formulations (all <0.01 mg/kg). In straw, low levels of residues were found from both formulations (0.03 mg/kg for PVP and 0.01 mg/kg for EC).
The trial data and residue results are summarized in Table 2.30.1-2.

Full study reference

Oxspring S (2007): Study on the residue behaviour of alphacypermethrin in sugar beet after treatment with BAS 310 40 I under field conditions in Southern Europe during 2006; BASF DocID 2007/1007941

Material and Methods:

A field program on sugar beets was conducted in the years 2002, 2003, 2005 and 2006 in France (Northern and Southern European region), Germany, Greece, Italy, and Spain.

Four residue trials were conducted on sugar beet during 2002, in Northern France. Two applications of alpha-cypermethrin, formulated as a wettable granule (WG 150 g/kg; BAS 310 08 I) were applied at a target rate of 7.5 g a.s./ha diluted with water immediately prior to application to a spray volume of 200 L/ha. The treatments were performed at growth stage 39 (Crop cover complete: leaves cover 90% of ground). Specimens of crop from the untreated and treated plots were taken by hand at normal commercial harvest.
Crop specimens were analysed for residues of alpha-cypermethrin by means of GC-MS using Agrisearch Method 'Alphacypermethrin/Crops/KLS/03/1', corresponding to the Cyanamid method SAMS 351-2 with a limit of quantitation (LOQ) of 0.01 mg/kg.

During the 2003 growing season, a total of 4 trials was conducted in sugar beets. BAS 310 03 I and BAS 310 QC I, both soluble concentrate formulations of alpha-cypermethrin (SC; 100 g a.s./L) were foliar applied once at a rate of 10 g a.s./ha to sugar beets. The treatment was done at growth stage 18 (8 leaves unfolded). Sugar beet whole plant specimens were collected directly after the last application from each plot at all locations. Sugar beet leaves (with tops) and roots were taken at growth stages 39 (crop cover complete, 14-30 days after application) and 49 (beet-root has reached harvestable size, 98-140 days after application).
The specimens were analysed for alpha-cypermethrin by means of HPLC-MS/MS with BASF analytical method No. 546/0 which has a LOQ of 0.05 mg/kg in all sample materials.

In the years 2005 and 2006, eight residue trials were performed in the Southern European region to investigate the residue behaviour of alpha-cypermethrin after application of a 100 g a.s./L emulsifiable concentrate formulation (EC; BAS 310 40 I). The product was foliar applied at a target rate of 25 g a.s./ha 14±1 days before harvest at growth stage 38 (leaves cover 80% of ground) to 49 (beet root has reached harvestable size). Samples of roots and leaves with tops were collected 0, 7, 14 and 21 days after application.
Residue analysis was performed by means HPLC-MS/MS according to BASF analytical method No. 567/0 with a LOQ of 0.01 mg/kg.

The trial data and residue results are summarised in Table 2.31.1-1.

_ underlined values were used for MRL calculation

Findings:

The residue data presented in the alpha-cypermethrin dossier were carried out in 5 different EU countries and provide data relevant to conditions in the Northern and Southern European region.
The proposed GAP is

- for the Northern European region: 1-2 applications with 15 g a.s./ha applied at infestation as an overall spray with a PHI of 14 days
- for the Southern European region: a single application with 30 g a.s./ha applied at infestation as an overall spray with a PHI of 7 days

The following residue studies were presented:

- two treatments at a target rate of 7.5 g a.s./ha-4 trials conducted in the Northern European region
- one treatment at a target rate of 10 g a.s./ha-4 trials each including two variants with different SC formulations, all conducted in the Northern European region
- one treatment at a target rate of 25 g a.s./ha-8 trials, all conducted in the Southern European region

No residues above the limit of quantitation of the analytical method (LOQ) were found after two treatments at a target rate of 7.5 g a.s./ha, applied at growth stage 18 in tops or roots sampled at normal harvest (PHI 84-92 days). Residues in all samples were <0.01 mg/kg.

Directly after application of BAS 310 I at a target rate of 10 g a.s./ha, alpha-cypermethrin residues in whole plant samples ranged between 0.138 and 0.446 mg/kg in case of BAS 310 03 I and between 0.098 and 0.335 mg/kg with BAS 310 QC I.
At the second sampling which took place after 14 to 30 days, alpha-cypermethrin was found in sugar beet tops at a level of <0.05 in three trials of variant BAS 310 03 I and between <0.05 and 0.070 mg/kg in variant BAS 310 QC I. In one trial of variant 310 03 I, residues in sugar beet tops were 0.292 mg/kg 21 days after application (trial DU2/02/03). At the same sampling date, residues in roots were 0.228 mg/kg in the same trial, while all other treated root samples did not show residues above the LOQ of the analytical method (all <0.05 mg/kg), regardless of sampling interval. Residues in sugar beet tops were below the LOQ at the last sampling, 98–131 days after application.

In eight trials that were performed in the Southern European region, one treatment at a target rate of 25 g a.s./ha was applied. Initial residues in sugar beet leaves with tops ranged between 0.220–0.777 mg/kg. Residues declined rapidly to 0.035–0.236 mg/kg, 0.026–0.159 mg/kg and <0.01–0.058 mg/kg 7, 14 and 21 days after application, respectively.
In sugar beet roots, there was one isolated finding of a residue slightly above the LOQ immediately after application (0.012 mg/kg; trial AF/10501/BA/1). In all other treated root samples no residues above the LOQ were found (all <0.01 mg/kg).

Conclusion:

A field program on sugar beets was conducted in the years 2002, 2003, 2005 and 2006 in France (Northern and Southern region), Germany, Greece, Italy, and Spain. In eight trials that support the proposed GAP for the Southern European region, residues in sugar beet leaves with tops ranged between 0.035–0.236 mg/kg at the target PHI of 7 days, while no residues above the LOQ (0.01 mg/kg) were found in sugar beet roots at the same time point.

2.31.2 Estimation of MRL, HR and STMR for sugar beet

For *sugar beet*, the following residue studies were considered (BASF DocIDs): 2003/1021716, 2004/1006468, 2006/1026851 and 2007/1007941.

The following residue values (PHI=14-92 days for EU-N and PHI=7 days for EU-S) were taken for STMR/HR/MRL calculation using the OECD MRL calculator:

Study report (BASF DocID)	Northern Europe (N-EU) [mg/kg]	Southern Europe (S-EU) [mg/kg]
2003/1021716	<0.01 (4x)	-
2004/1006468	<0.05 (3x), 0,228	-
2006/1026851	-	<0.01 (4x)
2007/1007941	-	<0.01 (4x)
OECD-MRL-calculation	**0.4 (n=8, STMR=0.03, HR=0.228)**	**<u>0.01</u> (n=8, STMR=0.01, HR=0.01)**

_ underlined values were used for risk assessment purposes

3 Dietary exposure assessment

3.1 Alpha-cypermethrin

The relevant calculations for parent alpha-cypermethrin are included in chapter CA 06.09.

3.2 Metabolites (TTC)

The following metabolites of alpha-cypermethrin were considered to be addressed in the dietary exposure calculations (see also Document N3):

Table 3.2-1: Overview: Relevant Metabolites of Alpha-Cypermethrin for Risk Assessment

Metabolite
M310I001
M310I003
M310I004
M310I005
M310I006
M310I007
M310I008
M310I009
M310I010
M310I011
M310I013
M310I017
M310I018
M310I019
M310I021
M310I024
M310I025
M310I026

In a first step the parent/metabolite ratios were derived from the respective metabolism studies as described in chapter CA 06.09.

Plant metabolism studies (see chapter CA 06.02 → cabbage: DocID AL-640-001, lettuce: DocID 2012/1084223, wheat: DocID AL-640-004)

Cabbage

The following TRR values were reported:

Table 3.2-2: Metabolism Study Cabbage: TRR Values (Stalk - B = worst case)

Metabolite	TRR [mg/kg]
Parent	0.1
M310I011	0.05
M310I013	0.05
M310I017	0.05
M310I024	0.05

Based on the molecular weights, the following parent/metabolite ratios were obtained:

Table 3.2-3: Cabbage: Parent/Metabolite Ratios Considering the Molecular Weights

Metabolite	Parent/Metabolite Ratio
Parent	1
M310I011	0.26
M310I013	0.28
M310I017	0.52
M310I024	0.24

When now assuming, that a cabbage head consists of about 45% outer leaves (old), about 45% outer leaves (new) and about 10% stalk, the following refinement can be made:

Considering the worst case parent/metabolite ratios (see Table 4 of DocID AL-640-001 → outer leaves (old) - B: **8.6 mg/kg** vs. **0.6 mg/kg**, outer leaves (new) - A: **0.4 mg/k**g vs. **<0.05** mg/kg, stalk - B: **0.1 mg/kg** vs. **0.05 mg/kg**) leads to a combined "cabbage refinement factor" of 0.14 ((45 x 0.07 + 45 x 0.125 + 10 x 0.5)/100).

When now also considering the molecular weights, the following parent/metabolite ratios were calculated:

Table 3.2-4: Cabbage: Parent/Metabolite Ratios (Based on a Combined "Cabbage Refinement Factor" of 0.14) Considering the Molecular Weights

Metabolite	Parent/Metabolite Ratio
Parent	1
M310I011	0.07
M310I013	0.08
M310I017	0.15
M310I024	0.07

Lettuce

M310I001		**1.83**		**0.01***		
M310I003		**0.93**		**0.00054****		

Most critical ratios were highlighted in bold

* as no parent value is available, as worst case for M310I001 (DCVA) the current feed burden level was compared to the feeding levels of the hen residue transfer study (DocID CY-870-018, Table 3) and the obtained residue values for DCVA. Due to a current feed burden level close to the 0.4 mg/kg-dose rate, a DCVA residue value of 0.01 mg/kg liver is considered to be relevant (this is an absolute value which will not be multiplied with STMR or HR values)

** this value was calculated by applying the TRR ratio of M310I001/M310I003 on the M310I001 residue value of 0.01 mg/kg liver considering the different molecular weights (this is an absolute value which will not be multiplied with STMR or HR values).

Lactating ruminants

3.2.1 Chronic Assessments

All chronic assessments were conducted using the EFSA PRIMo model (version 2). Chronic assessments were run against the trigger values 0.0000025 mg/kg bw (genotoxic), 0.0003 mg/kg bw (neurotoxic) and 0.0015 mg/kg bw (Cramer class III).

3.2.1.1 Chronic assessments applying the genotox-trigger value

The input values (parent/metabolite ratios) of Table 3.2-13 were multiplied with the STMRs of Table 3.2-14 and run against the trigger value 0.0000025 mg/kg bw using the EFSA PRIMo model (version 2).

In Table 3.2-15 to Table 3.2-32 the results of the EFSA PRIMo calculations are shown.

3.2.1.2 Chronic assessments applying the neurotox-trigger value

The input values (parent/metabolite ratios) of Table 3.2-13 were multiplied with the STMRs of Table 3.2-14 and run against the trigger value 0.0003 mg/kg bw using the EFSA PRIMo model (version 2).

In Table 3.2-33 to Table 3.2-50 the results of the EFSA PRIMo calculations are shown.

3.2.1.3 Chronic assessments applying the Cramer class III-trigger value

The input values (parent/metabolite ratios) of Table 3.2-13 were multiplied with the STMRs of Table 3.2-14 and run against the trigger value 0.0015 mg/kg bw using the EFSA PRIMo model (version 2).

In Table 3.2-51 to Table 3.2-68 the results of the EFSA PRIMo calculations are shown.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

12.7	**PL general population**	**4.1**	**Potatoes**	**1.9**	**Table grapes**	**1.7**	**Tomatoes**	**7.4**

Conclusion:

The estimated Theoretical Maximum Daily Intakes based on MS and WHO diets and pTMRLs were in the range of 12.7 % to 6103 % of the ADI.
For 23 diets the ADI is exceeded. Further refinements of the dietary intake estimates have not been performed. A public health risk can not be excluded at the moment.

Conclusion:
The estimated Theoretical Maximum Daily Intakes based on MS and WHO diets and pTMRLs were in the range of 0 % to 1153 % of the ADI.
For 11 diets the ADI is exceeded. Further refinements of the dietary intake estimates have not been performed. A public health risk can not be excluded at the moment.

Conclusion:
The estimated Theoretical Maximum Daily Intakes (TMDI), based on pTMRLs were below the ADI.
A long-term intake of residues of M310I003 is unlikely to present a public health concern.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

	DK adult		FRUIT (FRESH OR FROZEN)		FRUIT (FRESH OR FROZEN)		FRUIT (FRESH OR FROZEN)	

Conclusion:
The estimated Theoretical Maximum Daily Intakes (TMDI), based on pTMRLs were below the ADI.
A long-term intake of residues of M310I019 is unlikely to present a public health concern.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

	IT adult		FRUIT (FRESH OR FROZEN)		FRUIT (FRESH OR FROZEN)		FRUIT (FRESH OR FROZEN)	

Conclusion:
The estimated Theoretical Maximum Daily Intakes (TMDI), based on pTMRLs were below the ADI.
A long-term intake of residues of M310I003 is unlikely to present a public health concern.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

3.2.2 Acute Assessments

The acute assessments were conducted using the EFSA PRIMo model (version 2). Acute assessments were run against the trigger value of 0.005 mg/kg (Cramer class III).

The input values (parent/metabolite ratios) of Table 3.2-13 were multiplied with the HRs of Table 3.2-14 and run against the trigger value 0.005 mg/kg bw using the EFSA PRIMo model (version 2).

In Table 3.2-69 to Table 3.2-86 the results of the EFSA PRIMo calculations are shown.

Table 3.2-69: Acute Assessment of Metabolite M310I001 (Cramer class III trigger)

Acute risk assessment /children						Acute risk assessment / adults / general population					
The acute risk assessment is based on the ARfD.											
For each commodity the calculation is based on the highest reported MS consumption per kg bw and the corresponding unit weight from the MS with the critical consumption. If no data on the unit weight was available from that MS an average European unit weight was used for the ESTI calculation.											
In the **IESTI 1** calculation, the variability factors were 10, 7 or 5 (according to JMPR manual 2002), for lettuce a variability factor of 5 was used. In the **IESTI 2** calculations, the variability factors of 10 and 7 were replaced by 5. For lettuce the calculation was performed with a variabilty factor of 3.											
Threshold MRL is the calculated residue level which would leads to an exposure equivalent to 100 % of the ARfD.

4 Conclusion

The summarized results of the TTC calculations (input values see Table 3.2-14) for the metabolites on concern are given in the table below.

Table 4-1: Results of TTC calculations applying the genotoxic, neurotoxic and chronic (Cramer class III) TTC values (0.0000025, 0.0003 and 0.0015 mg/kg bw/d) as ADI and the ARfD of 0.005 mg/kg bw/d [Input values used are based on STMRs of alpha-Cypermethrin (chronic) and on HRs of alpha-CYP (acute) representing a refinement scenario]

Metabolite	Chronic assessment						Acute assessment	Occurrence			
	TTC genotox		TTC neurotox		TTC (Cramer class III)		ARfD exceeded?	Livestock		Rat	Plant

CA 6.1 Storage stability of residues

In the framework of the original inclusion into Annex I according to Directive 91/414/EEC, storage stability in crop commodities of high water (lettuce), starch (cereal grain) and oil (oilseed rape) content have been evaluated, as well as data on cattle tissues and milk.

Additional storage stability data in crop commodities of high water (tomato), acid (pineapple), starch (barley grain), protein (bean seed), and oil content (oilseed rape) are available in order to support the representative uses cucumber/courgette, leafy brassica, lettuce, barley, wheat and oil seed rape. These new studies will be summarized in the following.
Storage stability for animal matrices is not provided as no new feeding studies have been conducted.

Storage stability data supporting the terrestrial field dissipation are provided and are addressed under paragraph 7.1.2.2.1 in the application. Storage stability for water as matrix is not required.

An overview on the storage stability studies is presented in Table 6.1-1.

Table 6.1-1: Overview on storage stability studies

1 study was submitted in the context of the peer review under Directive 91/414/EEC, but it was not assessed
2 mentioned for completeness; will be addressed under 7.1.2.2.1

During the peer review under Directive 91/414/EEC, a storage stability study in lettuce (AL-726-015) was submitted. This study was not assessed in the 3rd Addendum to the Monograph: Addendum Chapter B-7 (Residue data), January 2003). This study was not included in the application as it had been submitted already with the alpha-cypermethrin addendum dossier. For the sake of completeness, it is summarized again below under point 6.1/1. All subsequent study summaries appear in the same sequence as indicated in the application, starting with 6.1/2.

Report:	CA 6.1/1 Mueller U., 1998a Alphacypermethrin (CL 900049): Storage stability of CL 900049 residues at < -18 C in lettuce (Germany, 1997) AL-726-015
Guidelines:	BBA IV 3-3, IVA Guideline Residue Chemistry Part II Storage Stability (1990), EEC 91/414 Annex II (Part A Section 6.2), EEC 91/414 Annex III (Part A Section 8.1)
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

In 1997 a study was initiated in order to investigate the stability of alpha-cypermethrin (CL 900049) residues in lettuce during storage at ≤ -18° C. This storage stability study was conducted using sample material with incurred residues of alpha-cypermethrin from a 1996 residue study. Aliquots of this sample material were analyzed for residues of alpha-cypermethrin after 0, 3, 6, 9 and 12 months storage at ≤ -18°C according to residue method FAMS 045-02 by means of capillary gas chromatography with nitrogen/phosphorus detection (GC/NPD).
No residues of alpha-cypermethrin were detected in any of the control samples, which had been stored at ≤ -18°C. Mean residue values obtained after 0, 3, 6, 9 and 12 month storage at ≤ -18°C from treated lettuce sample material with incurred alpha-cypermethrin residues ranged from 0.13 to 0.14 mg/kg. Concurrent recoveries for alpha-cypermethrin were performed at a level of 0.10 mg/kg and ranged from 73 to 98 %.
These results show that alpha-cypermethrin residues are stable in lettuce samples for at least 12 months, when residue samples are stored at ≤ -18°C.

I. MATERIAL AND METHODS

A. MATERIALS

1. **Test Material:** Alpha-cypermethrin CF 05898
Description: CF 05898 (EC)
Lot/Batch #: B011: 100 g/L
Purity: not reported
CAS#: 67375-30-8 alpha-cypermethrin
Development code: not reported
Spiking levels: 0.1 mg/kg

2. **Test Commodity:**
Crop: Lettuce
Type: Leafy vegetables
Variety: not reported
Botanical name: *Lactuca sativa*
Crop parts(s) or processed commodity: Leaves
Sample size: 15 g (aliquots)

B. STUDY DESIGN AND METHODS

1. Test procedure

An untreated and a treated sample from a lettuce residue study were used as sample material. The deep frozen lettuce samples were ground using a mincing machine.
At the start of the study (0 month storage), five aliquots of the treated sample material were analyzed together with one aliquot of the untreated sample for residues of alpha-cypermethrin in order to prove the homogeneity of the residue sample according to residue method FAMS 045-02 by means of capillary gas chromatography with nitrogen/phosphorus detection (GC/NPD). The limit of quantitation of the method (LOQ) was 0.01 mg/kg.
After 3, 6, 9 and 12 months storage at ≤ - 18°C, three aliquots of the treated sample together with one aliquot of the untreated sample were analyzed for residues of alpha-cypermethrin.
With each set of samples, two concurrent recoveries for alpha-cypermethrin were conducted in the range of the expected residue level (0.10 mg/kg). These concurrent recoveries were performed using the same untreated lettuce sample.

2. Description of analytical procedures

The method used for the analysis was FAMS 045-02 (Cyanamid Forschung GmbH) of March 31, 1995. A 15 g aliquot of sample material was extracted with 120 mL of hexane/acetone (8/2 v/v) using an Ultra-Turrax. The mixture was then centrifuged for 5 min at 3800 rpm (=2900 g). The extract solution was partitioned three times with 100 mL of water. The combined organic phases were reduced in volume almost to dryness by means of a rotary evaporator and the residue redissolved in 7.5 mL of acidic methanol. Further cleanup was carried out by gel permeation chromatography (GPC) by injecting an aliquot of this solution into the GPC system. The residues of alpha-cypermethrin were determined by capillary gas chromatography with nitrogen/phosphorus detection (GC/NPD). The limit of quantitation (LOQ) of the method was 0.01 mg/kg.

Method FAMS 045-02 is basically the same as method FAMS 066-01 which was employed in the storage stability study on alpha-cypermethrin in cereals AL-730-066, reviewed in the framework of the original inclusion into Annex I according to Directive 91/414/EEC. It only describes a solid phase extraction step as an alternative to gel permeation clean-up. The final extract is redissolved in cyclohexanone in method FAMS 045-02 instead of ethyl acetate as in method FAMS 066-01.
In the lettuce storage stability study described here, gel permeation clean-up was applied instead of a solid-phase extraction. Thus, the work-up procedure used was essentially the same as in the peer-reviewed cereal storage stability study AL-730-066. The gas chromatographic conditions applied in both studies were identical with the only exception of the purge valve off-on time (1.3 min for lettuce instead of 1.0 min for cereals).

Table 6.1-2: Summary of concurrent recoveries in lettuce

Matrix	Fortification Level (mg/kg)	Summary Recoveries				
		Recoveries (%)	n	Mean (%)	SD (+/-)	RSD (%)
Method FAMS 045-02		alpha-cypermethrin				
Lettuce	0.1	93, 96, 98, 96, 95, 91, 97, 95, 74, 73	10	91	9.3	10.3

II. RESULTS AND DISCUSSION

A summary of the frozen storage stability of alpha-cypermethrin residues in lettuce is given in Table 6.1-3.

No residues of alpha-cypermethrin were detected in any of the aliquots of the control sample, which had been stored at ≤ -18°C. Mean residue values obtained from the lettuce sample with incurred alpha-cypermetrin residues after 0, 3, 6, 9 and 12 month storage ranged from 0.14 to 0.13 mg/kg. Mean residue values, which were corrected for the average of concurrent recoveries obtained from each measuring date, ranged from 0.14 to 0.18 mg/kg.
Concurrent recoveries for alpha-cypermetrin were performed at a level of 0.10 mg/kg and ranged from 73 to 98 %. The average of all concurrent recoveries obtained during the study was 91 % (RSD = 10.3 %).
These results show that alpha-cypermethrin residues are stable in lettuce samples for at least 12 months, when residue samples are stored at ≤ -18°C.

Table 6.1-3: Summary of the storage stability of alpha-cypermethrin in lettuce

Storage period (months)	Mean recovery (%)		
	BAS 310 I found (mg/kg)	Concurrent BAS 310 I recovery (%)	BAS 310 I in stored samples, corrected for concurrent recovery (mg/kg)
0	0.14	95	0.15
3	0.14	97	0.14
6	0.14	93	0.15
9	0.14	96	0.15
12	0.13	74	0.18

III. CONCLUSION

The results of the storage stability study in lettuce show that alpha-cypermethrin residues are stable in lettuce samples for at least 12 months, when residue samples are stored at < -18°C.

Report:	CA 6.1/2 Mueller U., 1998b Alphacypermethrin (CL 900049): Storage stability of CL 900049 residues at < -18 degree C in tomatoes (Germany 1997) AL-723-029
Guidelines:	BBA IV 3-3, IVA Guideline Residue Chemistry Part II Storage Stability 1992, EEC 91/414 Annex II (Part A Section 6), EEC 91/414 Annex III 8.1
GLP:	yes (certified by Landesanstalt fuer Pflanzenbau und Pflanzenschutz Rheinland-Pfalz, Mainz)

Executive Summary

A freezer storage stability study was performed in order to investigate the stability of alpha-cypermethrin (BAS 310 I; former code: CL 900049) residues in tomatoes during storage at ≤ -18° C. In the course of the study 15 g aliquots of commercially purchased sample material were fortified with alpha-cypermethrin at a level of 0.10 mg/kg and stored in the deep freezer room. Immediately after the fortification, as well as after 3, 6, 9, and 12 months storage, fortified samples were analyzed together with one control sample for residues of alpha-cypermethrin according to residue method FAMS 045-02 by means of capillary gas chromatography with nitrogen/phosphorus detection (GC/NPD).

No residues of alpha-cypermethrin were detected in any of the control samples, which had been stored at ≤ -18° C. The mean residue value of alpha-cypermethrin obtained after 0 month (initial value) and 12 months storage (end value) at ≤ -18°C was 0.09 mg/kg, each. The mean residue values for alpha-cypermethrin obtained after 0, 3, 6, 9 and 12 months ranged from 0.08 to 0.10 mg/kg. Mean residue values from fortified tomato samples, which were corrected for the average of concurrent recoveries obtained from each set of samples, ranged from 0.09 to 0.10 mg/kg. Concurrent recoveries for alpha-cypermethrin were performed at a level of 0.10 mg/kg and ranged from 88 to 100 %.

These results show that alpha-cypermethrin residues in tomatoes are stable in frozen storage (≤ -18°C) for at least one year.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin (BAS 310 I; former code: CL 900049)
Description:
Lot/Batch #: AC 9575-006
Purity: 99.8%
CAS#: 67375-30-8 alpha-cypermethrin
Development code: not reported
Spiking levels: 0.10 mg/kg

2. Test Commodity:
Crop: Tomato
Type: Fruiting vegetables
Variety: not reported, commercially available sample material
Botanical name: *Lycopersicon esculentum*
Crop parts(s) or processed commodity: Fruit
Sample size: 15 g (aliquots)

B. STUDY DESIGN AND METHODS

1. Test procedure

In 1997 a study was initiated in order to investigate the stability of alpha-cypermethrin (BAS 310 I) residues in tomatoes during storage at ≤ - 18° C. In the course of the study 15 g aliquots of commercially purchased sample material were fortified with alpha-cypermethrin (BAS 310 I) at a level of 0.10 mg/kg and stored in the deep freezer room. Immediately after the fortification, as well as after 3, 6, 9, and 12 months storage, three fortified and one control sample, which was stored under the same conditions, were analyzed for residues of alpha-cypermethrin according to residue method FAMS 045-02 by means of capillary gas chromatography with nitrogen/phosphorus detection (GC/NPD). With each set of samples, two concurrent recoveries for alpha-cypermethrin were conducted in the range of the expected residue level (0.10 mg/kg).

2. Description of analytical procedures

The method used for the analysis was FAMS 045-02 (Cyanamid Forschung GmbH) of March 31, 1995. A 15 g aliquot of sample material was extracted with 120 mL of hexane/acetone (8/2 v/v) using an Ultra-Turrax. The mixture was then centrifuged for 5 min at 3800 rpm (=2900 g). The extract solution was partitioned three times with 100 mL of water. The combined organic phases were reduced in volume almost to dryness by means of a rotary evaporator and the residue redissolved in 7.5 mL of acidic methanol. Further cleanup was carried out by gel permeation chromatography (GPC) according to the method by injecting an aliquot of this solution into the GPC system. The residues of alpha-cypermethrin were determined by capillary gas chromatography with nitrogen/phosphorus detection (GC/NPD). The limit of quantitation (LOQ) of the method was 0.01 mg/kg.

Method FAMS 045-02 is basically the same as method FAMS 066-01 which was employed in the storage stability study on alpha-cypermethrin in cereals AL-730-066, reviewed in the framework of the original inclusion into Annex I according to Directive 91/414/EEC. It only describes a solid phase extraction step as an alternative to gel permeation clean-up. The final extract is redissolved in cyclohexanone in method FAMS 045-02 instead of ethyl acetate as in method FAMS 066-01.

In the tomato storage stability study described here, gel permeation clean-up was applied instead of a solid-phase extraction. Thus, the work-up procedure used was essentially the same as in the peer-reviewed cereal storage stability study AL-730-066. The gas chromatographic conditions applied in both studies were identical.

Method recoveries were analyzed with each set of stored samples. The results are summarized in Table 6.1-4.

Table 6.1-4: Summary of concurrent recoveries in tomato fruit

Matrix	Fortification Level (mg/kg)	Summary Recoveries				
		Recoveries (%)	n	Mean (%)	SD (+/-)	RSD (%)
Method FAMS 045-02		alpha-cypermethrin				
Tomato fruit	0.10	97, 94, 91, 91, 92, 93, 99, 100, 95, 88	10	94	3.8	4.0

II. RESULTS AND DISCUSSION

A summary of the frozen storage stability of alpha-cypermethrin residues in tomatoes is given in Table 6.1-5.

No residues of alpha-cypermethrin were detected in any of the control samples, which had been stored at ≤ -18° C.
The mean residue value of alpha-cypermethrin obtained after 0 months (initial value) and 12 months storage (end value) at ≤ -18°C was 0.09 mg/kg, each. The mean residue values for alpha-cypermethrin obtained after 0, 3, 6, 9 and 12 months ranged from 0.08 to 0.10 mg/kg. Mean residue values from fortified tomato samples, which were corrected for the average of concurrent recoveries obtained from each set of samples, ranged from 0.09 to 0.10 mg/kg. Concurrent recoveries for alpha-cypermethrin were performed at a level of 0.10 mg/kg and ranged from 88 to 100%. The average of all concurrent recoveries obtained during the study was 94 % (RSD = 4.0 %).

Table 6.1-5: Summary of the storage stability of alpha-cypermethrin in tomatoes

Storage period (months)	Mean recovery (%)		
	BAS 310 I found (mg/kg)	Concurrent BAS 310 I recovery (%)	BAS 310 I in stored samples, corrected for concurrent recovery (mg/kg))
0	0.09	96	0.09
3	0.08	91	0.09
6	0.09	93	0.10
9	0.10	100	0.10
12	0.09	92	0.10

III. CONCLUSION

These results show that alpha-cypermethrin residues in tomatoes are stable in frozen storage (≤ -18°C) for at least one year.

Report: CA 6.1/3
Dale T., 2003a
Alphacypermethrin - Freezer storage stability in oil seed rape (whole plant, whole pod and seed)
2003/1009948
Guidelines: none
GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Executive Summary

A freezer storage stability study was performed investigating the stability of alpha-cypermethrin in oilseed rape whole plant, whole pod and seed samples. The study was performed over a period of 12 months.
Specimens of oil seed rape whole plant, whole pod and seed which were fortified with BAS 310 I (alpha-cypermethrin) at 0.5 mg/kg, were analysed in duplicate after approximately 1.5, 3, 6 and 12 months. No initial data was obtained the first specimens were assayed after a nominal 1.5 months.
When corrected for concurrently performed recoveries none of the individual results obtained at the nominal 12 month timepoint (52 weeks) falls below 70.9%.
The results indicate that alpha-cypermethrin residues are stable in oilseed rape whole plant, whole pods and seeds under frozen conditions for at least 52-53 weeks.
An interim report was issued detailing the results up to and including the nominal 3 month timepoint. This study has already been peer-reviewed in the framework of the original inclusion into Annex I according to Directive 91/414/EEC (BASF RDI-No. AL-730-068; DocID 2002/1011586).
This final report includes all the data from the completed study.

I. MATERIAL AND METHODS

A. MATERIALS

1. **Test Material:** Alpha-Cypermethrin (BAS 310 I, former code: AC 900049)
Description:
Lot/Batch #: AC 12395-18
Purity: 95.1%
CAS#: 67375-30-8 alpha-cypermethrin
Development code: not reported
Spiking levels: 0.5 mg/kg

2. **Test Commodity:**
Crop: Oilseed rape
Type: Oilseeds
Variety: not reported
Botanical name: *Brassica napus*
Crop parts(s) or processed commodity: whole plant, whole pods, seeds
Sample size: 10 g (aliquots)

B. STUDY DESIGN AND METHODS

1. Test procedure

Aliquots of 10 g of each specimen matrix were weighed into screw top glass bottles. For every assay timepoint a set of 5 bottles were filled with specimen material. Two of these were fortified with BAS 310 I to give a level of 0.5 mg/kg. One was used as control and the other two used for concurrent procedural recoveries. Spare aliquots were also prepared in case of analytical problems or breakages. One group of specimens for each matrix were to be used to show that the control specimen was free of any contamination. This group consisted of two controls to assay.
The glass containers were tightly closed and transferred to a freezer. No initial specimens were taken for assay because the method could not be established within the analytical laboratory at this time. For the same reason no control group assays were done prior to fortification. The specimens were kept at a temperature of approximately minus 20°C in the dark over the entire period of the study until needed for an assay timepoint.
Specimen assay timepoints were at about 1.5, 3, 6 and 12 months.

An interim report provided results from the first two sampling intervals (6-weeks and 12 weeks) and was already evaluated (BASF RDI-No. AL-730-068; DocID 2002/1011586).

2. Description of analytical procedures

The samples were analyzed using the GC/NPD method, BASF Agro Research method RLA 12594V. The limit of quantification of this method was 0.05 mg/kg. This method was validated in study AL-244-007 (2000/7000960) which had been peer-reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414.

Method recoveries were analyzed with each set of stored samples. The results are summarized in Table 6.1-6.

Table 6.1-6: Summary of concurrent recoveries in oilseed rape matrices

Matrix	Fortification level (mg/kg)	Summary recoveries			
		n	Mean (%)	SD (%)	RSD (%)
BASF method No. RLA 12594V		**BAS 310 I**			
Whole plant	0.5	8	88.6	6.4	7.2
Whole pods	0.5	8	89.6	5.3	6.0
Seeds	0.5	8	97.1	5.0	5.2
Overall	0.5	24	91.8	6.6	7.2

II. RESULTS AND DISCUSSION

A summary of the frozen storage stability of alpha-cypermethrin residues in whole OSR plants, OSR pods, and OSR seeds is given in Table 6.1-7 - Table 6.1-9. In order to account for possible variations over the time investigated, the procedural recovery results are given in addition.The stability results are expressed as average percentage of the nominal fortification and are reported both uncorrected and as relative recovery after correction for procedural recovery. The stored recoveries were the actual percent of the residues recovered in the stored samples based on the amount of alpha-cypermethrin added to control samples. These recoveries give insight into the validity of the uncorrected residues reported in RAC and processing studies when stored under similar conditions. Corrected recoveries in stored samples equate to actual loss of residues during storage. Corrections were made for the experimental variability observed in the method spikes that were analyzed with the stored samples. Corrected recovery values above 70% were considered to indicate that the residues were stable.
Both the stored and corrected recoveries in the tested seed samples were above 70% when stored under frozen conditions for 12 months. In whole plant, a stored recovery value of 53.2% (corrected 60.5%) was found in one individual sample after 13 weeks, while the duplicate sample stored for the same time and analyzed at the same time point had a stored recovery of 72.2% (corrected 82.0%). Moreover, all whole plant samples analysed at later time points showed stored recoveries between 79.2-86.0% (corrected 87.3-99.3%); after 53 weeks, the mean stored uncorrected recovery lay at 85.15%. The isolated finding at 13 weeks storage should therefore be regarded as an outlier and not indicative of residue degradation during deep-frozen storage of rape seed whole plant specimen.

In oilseed rape whole pods, a trend to lower stored recoveries was observed beginning after 25 weeks of storage (25 weeks: 61.4/69.1%, corrected 73.1/82.3%; 53 weeks: 62.7/66.2%, corrected 70.9/74.8%). However, when corrected for concurrently performed recoveries none of the individual results obtained at the nominal 12 month timepoint falls below 70.9%.

In seeds, alpha-cypermethrin was recovered at more than 70 % during the whole time course of the study.
These results indicate that alpha-cypermethrin residues are stable in oilseed rape whole plant, whole pods and seeds under frozen conditions for at least 52-53 weeks.

	(98.0)	0.3616 (72.3)	0.3690 (73.8)
52 weeks	99 98	0.3680 (73.6)	0.3736 (74.7)
	(98.5)	0.3722 (74.4)	0.3779 (75.6)

1 concurrent procedural recoveries were performed in duplicate at each assay timepoint. The average procedural recovery value is shown in bold in brackets.
2 uncorrected
3 relative recovery= stored recovery/average procedural recovery x 100

III. CONCLUSION

The results indicate that alpha-cypermethrin residues are stable in OSR whole plant, whole pods and seeds under frozen conditions for at least 52-53 weeks.

Report: CA 6.1/4
Dale T., 2003b
Alphacypermethrin - Freezer storage stability in oil seed rape (whole plant, whole pod and seed)
2003/1009950
Guidelines: none
GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Executive Summary

A freezer storage stability study was performed investigating the storage stability of alpha-cypermethrin (BAS 310 I) in oilseed rape whole plant, whole pod and seed samples spiked at 0.5 mg/kg. The samples were analysed in duplicate after approximately 0, 1, 3, 6 and 11 months. When corrected for concurrently performed recoveries none of the individual results obtained at the nominal 11 month timepoint (48 weeks) falls below 70.7%.
The results indicate that alpha-cypermethrin residues are stable in oilseed rape whole plant, whole pods and seeds under frozen conditions for at least 48 weeks.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-cypermethrin (BAS 310 I, former code: AC 900049)
Description:
Lot/Batch #: AC 12395-18
Purity: 95.1%
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.5 mg/kg

2. Test Commodity:
Crop: Oilseed rape
Type: Oilseed
Variety: not reported
Botanical name: *Brassica napus*
Crop parts(s) or processed commodity: whole plant, whole pods, seeds
Sample size: 10 g (aliquots)

B. STUDY DESIGN AND METHODS

1. Test procedure

The freezer storage stability of alpha-cypermethrin residues over a period of 11 months was investigated using untreated control whole oil seed rape (OSR) plant, OSR pod, and OSR seed specimens.
Aliquots of 10 g of each specimen matrix were weighed into screw top glass bottles. For every assay timepoint a set of 5 bottles were filled with specimen material. Two of these were fortified with BAS 310 I to give a level of 0.5 mg/kg. One was used as control and the other two used for concurrent procedural recoveries. Spare aliquots were also prepared in case of analytical problems or breakages.
One group of specimens for each matrix were to be used to show that the control specimen was free of any contamination. This group consisted of two controls to assay and another two to act as concurrent procedural recoveries.
The glass containers were tightly closed and transferred to a freezer. Specimens analysed at the 0 timepoint were not taken to the freezer but were analysed immediately.
The specimens were kept at a temperature of approximately minus 20°C in the dark over the entire period of the study until needed for an assay timepoint. .
Specimen assay timepoints were at about 0, 1, 3, 6 and 11 months.

2. Description of analytical procedures

The samples were analyzed using the BASF Agro Research method RLA 12594V. The limit of quantitation of this method was 0.05 mg/kg.

Method recoveries were analyzed with each set of stored samples. The results are summarized in Table 6.1-10.

Table 6.1-10: Summary of concurrent recoveries in oilseed rape matrices

Matrix	Fortification level (mg/kg)	Summary recoveries			
		n	Mean (%)	SD (%)	RSD (%)
BASF method No. RLA 12594V		**BAS 310 I**			
Whole plant	0.5	10	92.7	4.0	4.3
Whole pods	0.5	12	88.5	3.6	4.0
Seeds	0.5	12	95.7	6.9	7.2
Overall	0.5	34	92.3	5.8	6.3

II. RESULTS AND DISCUSSION

The results of the analysis of the control samples used for spiking revealed no residues above the limit of quantitation for rape whole pods and seeds. No results for controls are available for whole plant specimens because of analysis failure. The results are shown in Table 6.1-11.

A summary of the frozen storage stability of alpha-cypermethrin residues in whole oilseed rape plants, pods, and seeds is given in Table 6.1-12–Table 6.1-14. In order to account for possible variations over the time investigated, the procedural recovery results are given in addition.The stability results are expressed as average percentage of the nominal fortification and are reported both uncorrected and as relative recovery after correction for procedural recovery. The stored recoveries were the actual percent of the residues recovered in the stored samples based on the amount of alpha-cypermethrin added to control samples. These recoveries give insight into the validity of the uncorrected residues reported in RAC and processing studies when stored under similar conditions. Corrected recoveries in stored samples equate to actual loss of residues during storage. Corrections were made for the experimental variability observed in the method spikes that were analyzed with the stored samples. Corrected recovery values above 70% were considered to indicate that the residues were stable.
Both the stored and corrected recoveries in the tested oilseed rape whole plant and seed samples were above 70% when stored under frozen conditions for approximately 49 and 48 weeks, respectively.
In oilseed rape whole pods, stored and corrected recoveries were higher than 70% up to and including a storage interval of 26 weeks. At the final time point of 48 weeks, the stored recoveries were 64.0/68.0%; however, the corrected recoveries still exceeded 70% (70.7/75.2%).

These results indicate that alpha-cypermethrin residues are stable in oilseed rape whole plant, whole pods and seeds under frozen conditions for at least 48 weeks.

Table 6.1-11: Analytical results for control matrices used

Matrix	BAS 310 I			
	Results of control (mg/kg)		Procedural recovery (%)	
Whole plant*	N/A	N/A	N/A	
Whole pod	<0.05	<0.05	84	80

III. CONCLUSION

The results indicate that alpha-cypermethrin residues are stable in oilseed rape whole plant, whole pods and seeds under frozen conditions for at least 48 weeks.

Report: CA 6.1/5
Porto F., 2014a
Investigation of the storage stability of Alphacypermethrin residues in pineapple (fruit), barley (grain) and bean (seed) at -20°C
2014/3006687

Guidelines: OECD 506 (Oct. 2007), FAO manual on submission and evaluation of pesticide residues data for the estimation of maximum residue levels in food and feed - Roma 2009 (Second edition), EEC 396/2005, EEC 7032/VI/95 rev. 5, EPA 860.1380

GLP: yes
(certified by Instituto Nacional de Metrologia, Normalizacao e Qualidade Industrial - INMETRO, Rio de Janeiro, Brazil)

Executive Summary

The stability of alpha-cypermethrin in pineapple (fruit), barley (grain) and bean (seed) at -20° C was investigated over a time period of at least 728 days.
Pineapple, barley and bean samples were spiked with the test item at the level of 0.1 mg/kg (10 x LOQ). After that, they were stored in a cold chamber under the usual storage conditions for laboratory samples, -20°C or lower, in the dark. Untreated control samples were fortified and analysed along with the five stored samples within each analytical series in order to prove the validity and applicability of the analytical method.
Residues found in the stored samples were corrected by the mean value of the fortified samples and were evaluated by means of an exponential function.
The samples were analysed by means of LC/MS/MS with an LOQ of 0.01 mg/kg (BASF method 567/0). The efficiency of the method was determined at each analysis time period by fortifying control samples with alpha-cypermethrin. The average recoveries for alpha-cypermethrin during the current study were 91.1 ± 10 (n=32), 88.5 ± 11 (n=19) and 90.1 ± 12 (n=19), pineapple, barley and bean respectively.
The results obtained from the stored fortified samples indicate that alpha-cypermethrin is stable at -20°C in pineapple, barley and bean samples for at least 728 days.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-cypermethrin (BAS 310 I, CL-No. 900049)
Description:
Lot/Batch #: L80-24
Purity: 99.4%
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.1 mg/kg

2. Test Commodity:

Crop:	1) Pineapple 2) Barley 3) Bean
Type:	1) Miscellaneous fruit, inedible peel, large 2) Oilseeds 3) Pulses
Variety:	not reported
Botanical name:	1) *Ananas comosus* 2) *Brassica napus* 3) not reported
Crop parts(s) or processed commodity:	1) Pineapple fruit 2) Barley grain 3) Bean seed
Sample size:	5 g (aliquots)

B. STUDY DESIGN AND METHODS

1. Test procedure

The stability of alpha-cypermethrin in pineapple (fruit), barley (grain) and bean (seed) at -20° C was investigated over a time period of at least 728 days. For each sampling interval, and each matrix, 11 samples of 5 g were prepared, stored at -20ºC or lower temperature and analyzed, as described below:
- 5 samples, which were spiked at the concentration of 10 x LOQ (0.1 mg/kg)
- 1 sample not spiked (control sample)
- 5 further controls for procedural recoveries were stored together with the samples. These samples were spiked just before analysis with a fresh solution which contained the active ingredients.

For each sampling interval, there was a set of backup samples.
The sampling of 0 day is an exception (analysis directly after samples spiking), where 6 instead of 11 samples were prepared (1 control and 5 samples spiked with the concentration of 10 x LOQ = 0.1 mg/kg, for each matrix).
The extraction containers were closed with caps and transferred into a cold chamber. The samples analyzed at day 0 (starting values) were not frozen, but were analyzed immediately after their preparation. The containers were kept at a temperature of about – 20oC or lower, in the dark, over the entire period of the experiment.
Pineapple, barley and bean samples containing alpha-cypermethrin were analyzed at 0 day, 29, 153, 202, 365, 544, 735 days (pineapple), 162, 365, 545, 729 days (barley) and 155, 365, 545, 728 days (bean).

2. Description of analytical procedures

The samples were analysed by means of LC/MS/MS with an LOQ of 0.01 mg/kg (BASF method 567/0).

Aliquots were extracted with 70/25/5 methanol/ water/HCl 2 mol/L (v/v/v), centrifuged, extracted with water / cyclohexane 5/25 (v/v) and centrifuged again. An aliquot was evaporated to dryness. The residue was dissolved in methanol/water (80/20), filtered if necessary, and finally the residues were determined by means of LC/MS/MS.

Method recoveries were analyzed with each set of stored samples. The results are summarized in Table 6.1-15.

Table 6.1-15: Summary of concurrent recoveries in pineapple fruit, barley grain and bean seed

Matrix	Fortification level (mg/kg)	Summary recoveries				
		Range	n	Mean (%)	SD (%)	RSD (%)[1)]

Barley grain	0.1	73.2-107	19	88.5	11	12
Bean seed	0.1	55.6-110	19	90.1	12	13

[1)] derived by dividing SD by Mean (values not reported)

II. RESULTS AND DISCUSSION

A summary of the frozen storage stability of alpha-cypermethrin residues in pineapple fruit, barley grain and bean seed for up to 728 days at -20°C or lower is given in Table 6.1-16 - Table 6.1-18. Recoveries from the stored fortified samples were corrected by procedural recoveries to account for experimental variability observed in the method spikes that were analyzed with the stored samples. The results obtained for barley: 0, 29 and 35 sampling days and for bean: 0, 29, 35 and 51 sampling days were not be reported in this final report due to recovery problems with the analytical method. Inclusion of new samples for these timepoints in the study was deemed not necessary since the analytical results from later time points clearly demonstrated storage stability of alpha-cypermethrin in barley grain and bean seeds.

All uncorrected and corrected average recoveries determined in the stored samples are clearly above 70 % for pineapple fruit, barley grain and bean seed, respectively, up to the end of the storage period.
The storage stability study demonstrates that residues of alpha-cypermethrin are stable for at least 728 days for beans, 729 days for barley and 735 days for pineapple, based on all the results described.

III. CONCLUSION

The storage stability study demonstrates that residues of alpha-cypermethrin are stable for at least 728 days for beans, 729 days for barley and 735 days for pineapple.

CA 6.2 Metabolism, distribution and expression of residues

CA 6.2.1 Metabolism, distribution and expression of residues in plants

In the framework of the original inclusion into Annex I according to Directive 91/414/EEC the following studies investigating of the metabolism of the active substance alpha-cypermethrin in plant were peer-reviewed: on vegetables (cabbage) and cereals (wheat). Studies were done using ^{14}C-benzyl-labelled alpha-cypermethrin or cis-cypermethrin, respectively (cabbage; AL-640-001), vinyl- and benzyl-^{14}C labeled alpha-cypermethrin (wheat, AL-640-002 and AL-640-003), or benzyl-(ring-U-^{14}C/7-^{13}C] and [cyclopropane-1-(^{14}C/^{13}C)] (wheat; AL-640-004). The characteristics of these studies are summarized in Table 6.2.1-1.

Table 6.2.1-1: Summary of metabolism studies in plants previously available

Group	Crop	Test substance	Label position	Method, F or G (a)	Rate (kg a.s./ha)	No	Sampling (DAT)	Year	DocID

(a): Outdoor/field application (F) or glasshouse/protected/indoor application (G)
DAT: Days after (last) treatment; DAT-n denoting day(s) after nth treatment)
1) as EC (100 g/L, EF05835)
2) in formulation based on recipe CF05898
3) formulated as FASTAC®

After three foliar applications at a rate equivalent to 50 g a.s./ha to **cabbage**, the level of total radioactive residues was higher in the old outer leaves than in the new ones indicating a lack of translocation. The principal constituant of the residue at harvest was the parent insecticide in the outer leaves and stalk of cabbage. *Cis-trans* isomerization had occurred in the leaves. The identification of the different metabolites and their quantification were tentatively investigated by TLC but not confirmed: *cis*- and *trans*-isomers of 4-hydroxy-cypermethrin (WL48393, WL48394), the amide analogue of cypermethrin (WL47133), 3-phenoxybenzoic acid (SD36750), 4-HO-3-PBA (WL46114) and 3-phenoxybenzyl alcohol (WL40673).

After a single foliar application at a rate equivalent either to 0.01 or 0.1 kg a.s./ha to **wheat**, alpha-cypermethrin was found to be a major constituent of the residue in wheat straw (~~24% to 44%~~ 45% to 53% TRR). 3-Phenoxybenzoic acid was also present at low level (3.3% of TRR)

After two foliar applications at a rate equivalent to 0.08 kg a.s./ha to **wheat**, major component of the residue in wheat forage, hay, straw and grain was found to be the parent alpha-cypermethrin which had undergone isomerization from cis- to trans-isomer in forage, hay and straw. In grain samples from the plot treated with cyclopropane label, the parent compound accounted for 22.5% of the TRR and was confirmed as being the unchanged cis-2 isomer. The unidentified fractions appeared to be a mixture of polar material and lignin-enriched radioactivity.

The incurred total radioactive residues in wheat forage, hay and straw included low levels of mono-ring-hydroxylated parent (4'-OH parent, max. 4.8 % TRR in straw 42 DALT), the ester hydrolysis products dichlororvinylcyclopropane acid (DCVA; max 2.3 and 1.5% of TRR for cis-DCVA and trans-DCVA, respectively, in straw 42 DALT) and the various phenoxybenozates (3-PBAld, 3-PBA, 3-PBAlc, 4'-OH-3-PBA and 3-PBA-amino acids; 0.2 % TRR - 1.2% TRR in forage, hay and straw). In grain 42 DALT, residues of 4'-OH parent, the phenoxybenzoates (3-PBAld, 3-PBA, 3-PBAlc, 4'-OH-3-PBA and 3-PBA-amino acids) and *cis*- and *trans*-DCVA were not detected (below limit of quantification).
Most of the identified metabolites in this wheat metabolism study are recovered in the rat metabolism and are therefore out of any toxicological relevance. The metabolites 3-PBAld and 3-PBAlc were not detected in the rat metabolism but were not present in wheat grain and were present at very low levels in the other matrices.

The metabolism studies performed between 1983 and 2001 show essential similarities: In all cases unchanged parent alpha-cypermethrin was reported to be the major compound. *Cis-trans* isomerization was observed. The metabolite 3-phenoxybenzoic acid (3-PBA) was found in all studies. While in the earlier wheat metabolism study only 3-PBA was identified as a metabolite, the later wheat and the cabbage study both demonstrated formation of 4-hydroxycypermethrin, 4'-OH-3-PBA and 3-phenoxybenzyl alcohol. *Cis*-DCVA and *trans*-DCVA were identified in the later wheat study after treatment with cyclopropane-labelled alpha-cypermethrin.

The degradation of alpha-cypermethrin in wheat and cabbage proceeded primarily via two independent pathways:

-oxidative ring hydroxylation of the phenyl ring
-hydrolysis at the ester linkage with the formation of 2 moieties:
a) the phenoxybenzoyl portion which leads to a multiplicity of metabolites as acids, aldehydes, alcohols and converted into amino acid conjugate;
b) the dichlorovinyl propane acid portion of the molecule (cis and trans-DCVA isomers)

In the cabbage metabolism study considerable amounts of the total radioactive residue could not be identified. The reason for incomplete identification is certainly due to the relative simplicity of the analytical equipment in the early 1980s. The thin layer chromatography used in this time was not potent and sensitive enough to detect minor components in very low absolute residue amounts.

Against this background it was intended to perform one more metabolism study. Considering the crop groups covered by metabolism studies as well as the intended uses it was decided to conduct a new metabolism study in lettuce as representative of the leafy vegetables.

Executive Summary

The objective of the present study was to investigate the metabolism of alpha-cypermethrin (BAS 310 I) in lettuce after foliar spray application. The test item was either labeled in the benzyl moiety or in the cyclopropane moiety. Lettuce was treated twice with BAS 310 I at a nominal application rate of 50 g a.s./ha at each application (approximately 0.045 lb/A). The lettuce heads were sampled 3 and 7 days after the last application (DALA). By enantiomer-specific analysis it was investigated whether an enantiomer of alpha-cypermethrin (BAS 310 I) is preferentially metabolized in lettuce.

The levels of total radioactive residues (TRR) at 3 DALA accounted for 0.873 mg/kg and 1.587 mg/kg for the benzyl label and the cyclopropane label, respectively. At 7 DALA, 1.318 mg/kg for the benzyl label and 1.372 mg/kg for the cyclopropane label were calculated.

For the investigations of metabolic patterns, subsamples of lettuce heads from both labels (benzyl and cyclopropane label) and both sampling time points (3 DALA and 7 DALA) were extracted with acetonitrile and water. The extractability of the radioactive residues from lettuce with acetonitrile and water was very high for both labels and both sampling time points (>97% TRR). The predominant part of the radioactive residues was extracted with acetonitrile, and only small portions were extracted with water. Due to low levels of radioactivity (up to approximately 2% TRR) in the residual radioactive residues after solvent extraction no further solubilization steps were performed.

Structural elucidation of metabolites was based on HPLC-MS investigations of isolated fractions from acetonitrile extracts. Peak assignment for BAS 310 I and its metabolites was based on comparison of the retention times of the isolated components with the ^{14}C-signals of the HPLC analyses. In the lettuce heads, BAS 310 I was the main component identified for both labels at 3 DALA and at 7 DALA (88.8 to 98.0% TRR). For the benzyl label, three metabolites (M310I005, M310I006 and M310I007) were identified, which lost the cyclopropane moiety and were therefore benzyl label-specific. For the cyclopropane label two label-specific metabolites (M310I008 and M310I009) were identified.

The metabolite M310I005 is a glucose conjugate of a proposed intermediate. M310I005 is subsequently metabolized via an acetylation reaction at the glucose moiety into M310I007, which was identified in the benzyl label at levels up to 4.9% TRR. The loss of the nitrile group of M310I007, which occurred presumably via hydrolysis and subsequent decarboxylation, leads to the formation of metabolite M310I006. The peak assigned to M310I005 and M310I006 accounted for up to 3.1% TRR. A second cleavage product of the ester bond hydrolysis is presumably 3-(2,2-dichlorovinyl)2,2-dimethylcyclopropanecarboxylic acid (DCVA), of which the glucose conjugate M310I008 was identified as metabolite in lettuce. This glycosylated compound is by malonylation on the glucose moiety metabolized into M310I009. The peak assigned to M310I008 and M310I009 accounted for up to 5.9% TRR.
The enantiomer-specific analyses showed that the ratio of enantiomer 1 to enantiomer 2 of BAS 310 I calculated from the HPLC analyses of the application solution was 1:1. The ratio found for fractions from lettuce extracts was similar to the enantiomer ratio in the application solution.
All samples were stored at approximately -18°C during the course of the study. All extractions were performed within less than three months after sampling. HPLC analyses were carried out within two months after extraction. Therefore, no storage stability investigations were necessary.
The extractability with three alternative extraction procedures according to residue methods for samples from both labels at 3 DALA was high (BASF residue analytical method 567/1: ≥92% TRR, multimethod QuEChERS: >75% TRR, multimethod DFG S19: >88% TRR), but the alternative extractions yielded slightly lower amounts of extracted radioactive residues than the acetonitrile/water extraction used in the metabolism study.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description:	a racemic mixture of two of the four cis isomers ((+)-*1R-cis-αS* and (-)-*1S-cis-αR*) comprising cypermethrin ^{14}C-alpha-cypermethrin (benzylring-U-^{14}C label) ^{13}C-alpha-cypermethrin (phenoxy-1,2,3,4,5,6-^{13}C label) ^{14}C-alpha-cypermethrin (cyclopropane-1-^{14}C label)
Lot/Batch #:	^{14}Calpha-cypermethrin (benzylring-U-^{14}C label): 775-0401 ^{13}Calpha-cypermethrin (phenoxy-1,2,3,4,5,6-^{13}C label): 1025-1034 ^{14}C-alpha-cypermethrin (cyclopropane-1-^{14}C label): 986-1046 ^{13}C-alpha-cypermethrin (cyclopropane-1-^{13}C label): 990-1024
Purity:	Radiochemical purity: ^{14}C-alpha-cypermethrin (benzylring-U-^{14}C label): 96.1% ^{14}C-alpha-cypermethrin (cyclopropane-1-^{14}C label): 98.2% Chemical purity: ^{14}C-alpha-cypermethrin (benzylring-U-^{14}C label): 93.7% ^{13}C-alpha-cypermethrin (phenoxy-1,2,3,4,5,6-^{13}C label): 95.1% ^{14}C-alpha-cypermethrin (cyclopropane-1-^{14}C label): 93.6% ^{13}C-alpha-cypermethrin (cyclopropane-1-^{13}C label): 97.7% Specific activity: ^{14}C-alpha-cypermethrin (benzylring-U-^{14}C label): 4.94 MBq/mg ^{14}C-alpha-cypermethrin (cyclopropane-1-^{14}C label): 4.9 MBq/mg
CAS#:	67375-30-8

Stability of test compound: All samples were stored at approximately -18°C during the course of the study. All extractions were performed within less than three months after sampling. HPLC analyses were carried out within two months after extraction. Therefore, no storage stability investigations were necessary.

2. Test Commodity:

Crop: Lettuce
Type: Leaf
Variety: Matilda
Botanical name: *Lactuca sativa*
Crop parts(s) or processed commodity: lettuce heads
Sample size: Not relevant

3. Soil: A sandy loam was used. The soil physicochemical properties are described below (see Table 6.2.1-2).

Table 6.2.1-2: Soil physicochemical properties

Soil series	Soil type	pH	OM %	Sand %	Silt %	Clay %	Maximal water holding capacity[1]	CEC[2] cmol/kg
Bruch West	*Sandy Loam	**7.3	***2.8	*63.7	*25.1	*11.3	29.2	11.9

* USDA scheme ** ($CaCl_2$) ***Organic matter calculated as 1.72 x percent organic carbon
1 in g/100 g dry soil
2 Cation exchange capacity

B. STUDY DESIGN

The study was carried out at the Agricultural Research Centre of BASF in Limburgerhof, Germany. The plant uptake part of the study was conducted in plastic containers located in climatic chambers and in the greenhouse, respectively.

1. Test procedure

Lettuce plants were planted into containers filled with sandy loam soil. The maintenance of the crop was performed in accordance with normal agricultural practice; fertilizers and additional pesticides were applied to achieve an adequate plant growth. According to the study protocol, the crop was treated twice with radiolabeled test items at a nominal rate of 50 g a.s./ha (approximately 0.045 lb/A) at each application. The first application was carried out 17 days before the last sampling date; the second was performed 7 days before the last sampling date. Samples of lettuce were taken 3 and 7 days after last application (DALA).

The in-life part was performed with two ^{14}C-labeled test substances, one radiolabeled in the benzyl ring (benzyl label) and the other in the cyclopropane ring (cyclopropane label). The ^{14}C-labeled test items were mixed with a ^{13}C-labeled test item each in a ratio of 2:1. For the preparation of the application formulation with the radiolabeled benzyl label and cyclopropane label, calculated amounts of ^{14}C-benzyl labeled and ^{13}C-phenoxy-1,2,3,4,5,6 labeled test items and calculated amounts of ^{14}C-cyclopropane labeled and ^{13}C-cyclopropane labeled test items were weighed, respectively.
The test item mixtures were dissolved in the blank formulation BAS 310 DZ I and water. Thereafter, the mixture was sonicated to generate a homogenous emulsion. The purity of the application solutions was confirmed using HPLC method and the isotope pattern were analysed by GC-CI-MS analysis.
The application formulations were applied with an automatic spray track at actual total application rates of 99.7 g a.s./ha for the benzyl label and of 101.9 g a.s./ha for the cyclopropane label (corresponding to a spray volume of 221.9 L/ha (benzyl label) and of 218.4 L/ha (cyclopropane label). Considering the loss recovered in the washing liquids of the spray track system, 99.28% (benzyl label) and 99.19% (cyclopropane label) of the application solution were actually applied as well as 99.05% (benzyl label) and 99.20% (cyclopropane label) at the second application.
Samples of lettuce were taken 3 and 7 days after last application (DALA) homogenized and frozen at -18°C or below. Extracts were stored in a refrigerator or, for longer periods in a freezer.

2. Description of analytical procedures

Combustion: Homogenized solid plant samples were weighed, pressed and combusted by means of an automatic sample oxidizer. The $^{14}CO_2$ was trapped by an absorption and scintillation liquid, and the collected radioactivity was measured by liquid scintillation counting. ^{14}C standards were combusted to determine the recovered radioactivity and the measurements were corrected accordingly. In order to determine the background radioactivity, aliquots of untreated lettuce samples were combusted under the same conditions. This resulted in a measured background activity of 0 dpm/g. Therefore, the limit of quantitation in mg/kg was not calculated from the background radioactivity level.
Homogenization / solvent extraction: All samples were homogenized with dry ice. After sublimation of the dry ice, the samples were weighed and radioassayed. Lettuce homogenized plant material was extracted with acetonitrile and with water. After centrifugation, the supernatant was filtered and the corresponding acetonitrile extracts and water extracts were pooled. Extracts were concentrated, analysed using HPLC and radioassayed (LSC). The residue after solvent extraction was dried, homogenized and radioassayed
Metabolite isolation for MS and enantiomer-specific analysis: Radioassayed, concentrated lettuce extracts (7 DALA) were redissolved in acetonitrile / water (1/9), loaded on a preconditioned SPE column and cleaned-up.
The eluates were analyzed by HPLC and HPLC-MS. In addition, enantiomer-specific analysis (both labels) was performed using HPLC.
HPLC: Extracts were concentrated, assayed by LSC (liquid scintillation counter for the quantitation of radioactivity in liquid samples) and characterized by HPLC. Metabolite patterns were confirmed using further HPLC methods.

LSC measurement of liquid samples: For the quantitation of radioactivity in liquid samples a liquid scintillation counter (LSC) was used. Aliquots of liquid samples were mixed with a sufficient volume of a suitable scintillator prior to measurement. All data were corrected using appropriate quench curves and are expressed in decays per minute (dpm).
Extraction procedures according to Residue Methods:
In addition to the solvent extractions, samples from 3 DALA of both labels were extracted following alternative extraction protocols according to residue methods. According to BASF residue analytical method 567/1 extraction was performed using a solvent mixture of methanol, water and HCl. The supernatants were radioassayed and analyzed using HPLC. Further extraction procedures according to multimethod QuEChERS and multimethod DFG S19 were performed and supernatants were concentrated and subsequently analyzed using HPLC.
Storage Stability:
Since storage intervals for frozen plant samples prior to extraction were below three months and for the extracts prior to HPLC analysis were below two months, respectively, no storage stability investigations were performed.
Calculations:
All calculations were performed with the complete numerical data exported from the LIMS. The numerical data were generally shown as rounded values (smaller degree of precision) to increase readability.

3. Identification of metabolites

The structure elucidation of metabolites was based on HPLC-MS investigations of isolated fractions from acetonitrile extracts 7 DALA of both labels. The identification (peak assignment) was based on comparison of the retention times of the isolated components with the ^{14}C-signals of the quantitative and confirmatory HPLC analyses.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

The TRR was calculated by summarizing the extractable radioactive residues (ERR) and the residual radioactive residues (RRR) after solvent extraction. The calculated TRR for the benzyl label sampled 3 DALA was 0.873 mg/kg and 1.318 mg/kg at 7 DALA (see Table 6.2.1-3). For the cyclopropane label, the TRR for lettuce sampled 3 DALA and 7 DALA was 1.587 mg/kg and 1.372 mg/kg, respectively. Additionally, the TRR was measured by direct combustion analysis followed by LSC. The measured TRR of both labels of 3 DALA showed no major differences to the calculated TRR values. For 7 DALA, the calculated and measured concentrations differed to some extend (benzyl label: 2.433 mg/kg for TRR measured and 1.318 mg/kg for TRR calculated, cyclopropane label: 1.977 mg/kg for TRR measured and 1.372 mg/kg for TRR calculated). The differences were most probably due to slight inhomogeneity.
No background radioactivity was measured (0 dpm); therefore no calculation of the limit of quantitation could be performed.

Table 6.2.1-3: Total radioactive residues (TRRs) in lettuce samples

Matrix	DALA[1]	TRR determined by direct combustion [mg/kg]	TRR calculated [mg/kg]*
Lettuce head		Benzyl label	
	3	0.814	0.873
	7	2.433	1.318
		Cyclopropane label	
	3	1.538	1.587
	7	1.977	1.372

1 DALA = Days after last application
* Sum of ERR (extraction with acetonitrile and water) and RRR (extraction residue)

B. EXTRACTION, CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

The extractability of lettuce for the two labels and two time points with acetonitrile and water is summarized in Table 6.2.1-4.

Table 6.2.1-4: Extraction efficiency of radioactive residues in lettuce samples

Matrix	DALA[1]	TRR calculated*	Distribution of radioactive residues				ERR[2]		RRR[3]	
			Acetonitrile extract		Aqueous extract					
		[mg/kg]	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]	[mg/kg]	[%TRR]
Lettuce head		Benzyl label								
	3	0.873	0.851	97.5	0.005	0.5	0.856	98.0	0.017	2.0

	7	1.372	1.340	97.6	0.012	0.9	1.352	98.5	0.021	1.5

1 DALA = Days after last application
* TRR was calculated as the sum of ERR + RRR
2 ERR = extractable radioactive residue, calculated as the sum of acetonitrile extract and water extract
3 RRR = residual radioactive residue

1. Extraction and characterization of residues in lettuce

The extractability of lettuce with acetonitrile and water was very high and accounted for 97.7 to 98.8% of the TRR. For the benzyl label 97.5% TRR (3 DALA) and 96.9% TRR (7 DALA) were extracted with acetonitrile, whereas for the cyclopropane label 98.2% TRR (3 DALA) and 97.6% TRR (7 DALA) were extracted. Thus, virtually the complete radioactivity was extracted with acetonitrile and the subsequent water extraction released only minor amounts of 0.5 to 0.9% TRR.

Table 6.2.1-5: Metabolites detected in lettuce

Components	Acetonitrile extract (3 DALA)				Sum of extracts* (7 DALA)			
	Benzyl label		Cyclopropane label		Benzyl label		Cyclopropane label	
	[mg/kg]	[%TRR[2]]	[mg/kg]	[%TRR[2]]	[mg/kg]	[%TRR[2]]	[mg/kg]	[%TRR[2]]

2 TRR = total radioactive residue

2. Identification and quantitation of extractable residues in lettuce

Benzyl label, 3 DALA

Analysis of the acetonitrile extract of lettuce using HPLC method resulted in a pattern of three peaks, which were all identified. The main peak was found to be the parent compound BAS 310 I and accounted for 0.814 mg/kg or 93.3% TRR. The second peak was assigned to M310I005 and M310I006 and accounted for 0.027 mg/kg or 3.1% TRR, while the third peak, metabolite M310I007 was identified at a level of 0.021 mg/kg or 2.4% TRR.

In the water extract only minor amounts of radioactive residues were measured (0.005 mg/kg or 0.5% TRR) in the radioassay. Due to low levels of radioactivity (0.017 mg/kg or 2.0% TRR), the RRR after solvent extraction was not further solubilized. The results of the analysis of lettuce sampled 3 DALA (benzyl label) are compiled in Table 6.2.1-5. In summary, 98.7% of the total radioactive residues were identified in the ERR.

Benzyl label, 7 DALA

In the acetonitrile extract the same components as in the acetonitrile extract from lettuce sampled after 3 DALA were identified with HPLC. Likewise, the parent compound BAS 310 I was the main constituent at 1.171 mg/kg or 88.8% TRR. The second peak, metabolites M310I005 and M310I006 accounted for 0.026 mg/kg or 2.0% TRR, while the third peak, metabolite M310I007 was identified at a level of 0.061 mg/kg or 4.6% TRR.

Analysis of the water extract using HPLC resulted in a pattern of three peaks, of which two were identified. These are the more polar metabolites M310I005 and M310I006 as well as the metabolite M310I007 which were identified at levels of up to 0.3% TRR.

In the ERR, 96.1% of the total radioactive residues were identified and 0.1% TRR were characterized by HPLC. The RRR after solvent extraction was, due to low levels of radioactivity (0.030 mg/kg or 2.3% TRR), not further solubilized. Results of the sum of acetonitrile and water extracts of lettuce sampled 7 DALA (benzyl label) are summarized in Table 6.2.1-5.

Cyclopropane label, 3 DALA

Analysis of the acetonitrile extract of lettuce using HPLC resulted in a pattern of two peaks, which were both identified. The main peak was found to be the parent compound BAS 310 I and accounted for 1.556 mg/kg or 98.0% TRR. The second peak (assigned to M310I008 and M310I009) accounted for 0.049 mg/kg or 3.1% TRR.

In the water extract only minor amounts of radioactive residues were measured (0.010 mg/kg or 0.6% TRR) in the radioassay. Due to low levels of radioactivity (0.019 mg/kg or 1.2% TRR), the RRR after solvent extraction was not further solubilized. In the ERR 101.1% of the total radioactive residues were identified. The results of the analysis of lettuce sampled 3 DALA (cyclopropane label) are summarized in Table 6.2.1-5.

Cyclopropane label, 7 DALA

In the acetonitrile extract the same components as in the acetonitrile extract from lettuce sampled after 3 DALA were identified with HPLC. Likewise, the parent compound BAS 310 I was the main constituent at 1.271 mg/kg or 92.6% TRR. The remaining peak, which consists of M310I008 and M310I009, accounted for 0.076 mg/kg or 5.6% TRR. Analysis of the water extract using HPLC resulted in a pattern of three peaks, of which one was identified. M310I008 and M310I009 (assigned to the peak) accounted for 0.005 mg/kg or 0.4% TRR. In the ERR, 98.5% of the total radioactive residues were identified and 0.5% TRR were characterized by HPLC. The RRR after solvent extraction was, due to low levels of radioactivity (0.021 mg/kg or 1.5% TRR), not further solubilized. Results of the sum of acetonitrile and water extracts of lettuce sampled 7 DALA (cyclopropane label) are summarized in Table 6.2.1-5.

Enantiomer Ratio of BAS 310 I

In order to analyze if one enantiomer of BAS 310 I was preferably metabolized in lettuce, enantiomer-specific analyses were performed.

For the application solution the ratio of enantiomer 1 to enantiomer 2 was found to be approximately 1:1 for both labels (benzyl and cyclopropane label). For the determination of the enantiomer ratio in lettuce samples, the parent compound was isolated from fractions of the acetonitrile extract of both labels at 7 DALA and analyzed using HPLC. Thereby, a similar ratio of enantiomer 1 to enantiomer 2 was calculated compared to the application solution. The origin of a slight shoulder in front of the second peak could not be addressed as cypermethrin isomers, neither by HPLC analysis of the acetonitrile extracts of both labels nor by analysis of the diluted application solutions using UV chromatograms. The amounts of the parent substance were too low for detection.

3. Metabolic pathway

The proposed metabolic pathway of BAS 310 I (alpha-cypermethrin) in lettuce is shown in Figure 6.2.1-1.

A first step of the metabolism of BAS 310 I in lettuce after foliar application is the hydrolysis of the ester bond which releases two proposed intermediates. One of these intermediates is in a further step conjugated to a glucose resulting in the detected metabolite M310I005. Subsequent to the glucose conjugation reaction, M310I005 is acetylated at the glucose moiety resulting in the formation of the metabolite M310I007. The loss of the nitrile group of M310I007 (presumably via hydrolysis and subsequent decarboxylation) leads to the formation of metabolite M310I006.

The second cleavage product of the ester bond hydrolysis is presumably 3-(2,2-dichlorovinyl)2,2-dimethylcyclopropanecarboxylic acid (DCVA), which was not detected in this study. Nevertheless, was the glucose conjugate of DCVA, which was code-named M310I008 identified as a metabolite in lettuce. This conjugate is by malonylation on the glucose moiety metabolized to M310I009, the corresponding DCVA malonylglucose.

4. Extraction procedures according to Residue Methods

Additional to the acetonitrile and water extractions of the metabolism investigations samples of both labels from 3 DALA were also extracted with alternative extraction procedures according to residue methods.

The extraction procedure according to BASF residue analytical method 567/1, the method adapted from the multimethod QuEChERS and the extraction procedure according to multimethod DFG S19 resulted in slightly lower amounts of extracted radioactive residues than the acetonitrile/water extraction used in the metabolism study, except for the multimethod DFG S19 where for the benzyl label 3 DALA one slightly higher extractability was detected (Table 6.2.1-6). The concentrated solvent supernatants of the alternative extraction methods were analyzed using HPLC. The results of the HPLC analyses are summarized in Table 6.2.1-7.

Table 6.2.1-6: Extraction efficiency of radioactive residues in lettuce samples obtained with extraction procedures according to residue methods

Matrix	DALA[1]	Metabolism investigations (3 x acetonitrile + 2 x water)[3]		BASF residue analytical method 567/1		Multimethod QuEChERS		Multimethod DFG S19	
		[mg/kg]	[%TRR][2]	[mg/kg]	[%TRR][2]	[mg/kg]	[%TRR][2]	[mg/kg]	[%TRR][2]

		Cyclopropane label							
	3	1.569	98.8	1.465	92.3	1.204	75.9	1.409	88.8

1 DALA = Days after last application
2 TRR was calculated as the sum of ERR + RRR
3 Calculated as sum of the pooled extracts, method used for quantitation of residues

Table 6.2.1-7: Total identified radioactive residues extracted from lettuce samples 3 DALA with extraction procedures according to residue methods

Extraction method	Metabolism investigations	BASF residue analytical method 567/1	Multimethod QuEChERS	Multimethod DFG S19
Metabolite	[% TRR]			
	Benzyl label			
BAS 310 I	93.3	76.1	85.4	83.5
M310I005 / M310I006	3.1	4.4	2.8	1.9
M310I007	2.4	1.4	1.8	0.7
	Cyclopropane label			
BAS 310 I	98.0	79.8	71.3	75.0
M310I008 / M310I009	3.1	1.6	2.7	2.1

5. Storage stability

All samples were stored in a freezer (–18°C or below) directly after sampling until used. Subsamples of lettuce sampled 3 DALA and 7 DALA of both labels were extracted 2 to 18 days after sampling. Aliquots of extracts were analyzed for quantitation and confirmation by HPLC within 33 days after extraction. Enantiomer-specific analysis was performed 35 days after extraction, while fractionation of extracts was performed 17 to 59 days after extraction. Subsamples used for alternative solvent extraction procedures were extracted 70 to 74 days after sampling and analyzed by HPLC within the next 2 days.
Since the storage intervals for the frozen plant samples prior to extraction were below three months and the storage intervals for the extracts prior to the HPLC analysis were below two months, no storage stability investigations were necessary.

III. CONCLUSION

The insecticide alpha-cypermethrin (BAS 310 I), which was radioactive labeled in the benzyl or in the cyclopropane moiety, was applied to lettuce by two foliar applications at a nominal rate of 2 x 50 g a.s./ha. The lettuce heads were sampled 3 days and 7 days after the last application.
The levels of total radioactive residues (TRR) at 3 DALA accounted for 0.873 mg/kg and 1.587 mg/kg for the benzyl label and the cyclopropane label, respectively. At 7 DALA, 1.318 mg/kg for the benzyl label and 1.372 mg/kg for the cyclopropane label were calculated.
The extractability of the radioactive residues from lettuce with acetonitrile and water was very high for both labels and both sampling time points (>97% TRR). The predominant part of the radioactive residues was extracted with acetonitrile, and only small portions were extracted with water. Due to low levels of radioactivity (up to approximately 2% TRR) in the residual radioactive residues after solvent extraction no further solubilization steps were performed.

Structural elucidation of metabolites was based on HPLC-MS investigations of isolated fractions from acetonitrile extract of the benzyl label at 7 DALA. In these fractions, additional to the parent compound the metabolites M310I005, M310I006 and M310I007 were identified. HPLC-MS analyses of an isolated fraction from acetonitrile extract of the cyclopropane label at 7 DALA identified M310I008 and M310I009 as label-specific metabolites. The peak assignment for BAS 310 I and its metabolites was based on comparison of the retention times of the isolated components with the ^{14}C-signals of the HPLC analyses.

In the lettuce heads, BAS 310 I was the main component identified for both labels at 3 DALA and at 7 DALA (>88% TRR). For the benzyl label, three metabolites (M310I005, M310I006 and M310I007) were identified, which lost the cyclopropane moiety and were therefore benzyl label-specific. For the cyclopropane label two label-specific metabolites (M310I008 and M310I009) were identified.
An ester bond cleavage of the parent compound leads presumably to two cleavage products. Those intermediates were not detected in this study, but due to a low level of metabolized parent compound, low amounts of cleavage products are expected.
The metabolite M310I005 is a glucose conjugate of one of the proposed intermediates. M310I005 is subsequently metabolized via an acetylation reaction at the glucose moiety into M310I007, which was identified in the benzyl label at levels up to 5% TRR. The loss of the nitrile group of M310I007, which occurred presumably via hydrolysis and subsequent decarboxylation, leads to the formation of metabolite M310I006. The peak assigned to M310I005 and M310I006 accounted for up to approximately 3% TRR.
The second cleavage product of the ester bond hydrolysis is presumably 3-(2,2-dichlorovinyl)2,2-dimethylcyclopropanecarboxylic acid (DCVA), of which the glucose conjugate M310I008 was identified as metabolite in lettuce. This glycosylated compound is by malonylation on the glucose moiety metabolized to M310I009. The peak assigned to M310I008 and M310I009 accounted for up to approximately 6% TRR.
The enantiomer-specific analyses showed that the ratio of enantiomer 1 to enantiomer 2 of BAS 310 I calculated from the HPLC analyses of the application solution was 1:1. The ratio of fractions from lettuce extracts was similar to the enantiomer ratio in the application solution.
The extractability with three alternative extraction procedures for samples from both labels at 3 DALA was high (BASF residue analytical method 567/1: ≥92% TRR, multimethod QuEChERS: >75% TRR, multimethod DFG S19: >88% TRR), but the alternative extractions yielded slightly lower amounts of extracted radioactive residues than the acetonitrile/water extraction used in the metabolism study. All methods allow extracting and determining the parent compound with high recoveries (>75%).

Figure 6.2.1-1: Proposed metabolic pathway of alpha-cypermethrin (BAS 310 I) in lettuce

Overall Summary of Plant Metabolism

The present Annex I renewal dossier provides a new metabolism study in lettuce as representative for leafy vegetables. The new study mainly confirms the findings and degradation reactions known so far and complements additional details due to more sensitive technology.

Combining the findings of the older metabolism studies and the new one, a system of degradation reactions results which can not only explain most of the facts gathered so far but also lead to a more complete picture.

In all studies, the parent is the major residue constituent in the RAC. *Cis*/*trans* isomerization of BAS 310 I was observed in wheat and cabbage which can be attributed to sunlight exposure. In lettuce (indoor study), no difference in the BAS 310 I isomer ratio was found compared to the application solution, which could probably be attributed to the shorter PHI and as such to the shorter exposure to artificial light.

Common in all metabolism studies is the hydrolysis at the ester linkage with the formation of two moieties, the phenoxybenzoyl portion and the dichlorovinyl cyclopropane acid portion of the molecule. Oxidative ring hydroxylation of the phenyl ring was observed only in wheat and cabbage.
In **lettuce**, the alpha-cypermethrin cleavage products (M310I001 (DCVA) and the phenoxybenzoyl moiety) were not detected, but due to a low level of metabolized parent compound, low amounts were to be expected. From the proposed intermediate DCVA a glucose conjugate is formed (M310I008), which is further metabolized to M310I009 by malonylation on the glucose moiety. The phenoxybenzoyl portion is conjugated with glucose to form M310I005. M310I005 is subsequently metabolized via an acetylation reaction at the glucose moiety into M310I007. The loss of the nitrile group of M310I007, which occurred presumably via hydrolysis, leads to the formation of metabolite M310I006.
In **wheat**, low levels of the cleavage product DCVA were detected. The phenoxybenzoyl portion was metabolized to the various phenoxybenozates (3-PBAld, 3-PBA, 3-PBAlc, 4'-OH-3-PBA and 3-PBA-amino acids). 3-phenoxybenzoic acid, 4-HO-3-PBA and 3-phenoxybenzyl alcohol (WL40673) were also detected in **cabbage**.
The difference in the metabolites found resulting from cleavage of alpha-cypermethrin in lettuce as compared to cabbage and wheat can be mainly attributed to the considerably shorter PHI/sampling intervals in the lettuce study.

A complete picture on plant metabolism is shown in Figure 6.2.1-2.

Application of separated leaf cell suspension to Xenobiotic - Metabolism in plant
2009/1131382
Guidelines: none
GLP: no

Executive Summary

Metabolic profiles of ^{14}C-labeled primary metabolites from several pesticides, 4-cyanophenol **(1)**, 3-phenoxybenzoic acid **(2)**, 3-phenoxybenzyl alcohol **(3)**, 3,5-dichloroaniline **(4)**, and (1RS)-trans-2,2-dimethyl-3-(2-methylprop-1-enyl)cyclopropanecarboxylic acid **(5)**, were examined by using enzymatically separated leaf cell suspension from seedlings of cabbage (*Brassica oleracea*) and tomato (*Lycopersicon esculentum*). After 1 day of incubation, the metabolites were extensively transformed in cabbage, whereas they were scarcely metabolized in tomato. The major metabolic pathways were the phase II reactions leading to a number of conjugates such as glucoside/malonylglucoside of **1-5**, malate of **2**, and glutamate of **4**. The oxidation of **1** and **2** was observed as a minor reaction to produce 4-hydroxybezoic acid and 3-(4-hydroxyphenoxy)benzoic acid. The chemical identities of the secondary metabolites were determined by various spectrometric analyses (LC-MS, LC-MS/MS, and NMR) and/or HPLC cochromatography with the synthetic reference standards. As a result, this separated leaf cell suspension system was found to well reproduce the in vivo plant metabolism.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: ^{14}C labelled 4-cyanophenol **(1)**,
^{14}C labelled 3-phenoxybenzoic acid **(2)**,
^{14}C labelled 3-phenoxybenzyl alcohol **(3)**,
^{14}C labelled 3,5-dichloroaniline **(4),**
^{14}C labelled (1RS)-trans-2,2-dimethyl-3-(2-methylprop-1-enyl)cyclopropanecarboxylic acid **(5)**

Description: ^{14}C phenyl ring labelled (0.82 GBq/mmol) 4-cyanophenol **(1)**,
^{14}C phenoxyphenyl ring labelled (2.45 GBq/mmol) phenoxybenzoic acid **(2)**,
^{14}C phenoxyphenyl ring labelled (2.25 GBq/mmol) phenoxybenzyl alcohol **(3)**,
^{14}C phenyl ring labelled (2.22 GBq/mmol) 3,5-dichloroaniline **(4)**
^{14}C cyclopropyl-1 ring labelled (0.98 GBq/mmol) (1RS)-trans-2,2-dimethyl-3-(2-methylprop-1-enyl)cyclopropanecarboxylic acid **(5)**

Lot/Batch #: not reported
Purity: Radiochemical purity for compound **1-5** >97%
CAS#: not applicable
Development code: not applicable
Stability of test Compound: not reported

2. Test Commodity: Brassica vegetables, Fruiting vegetables
Crop: Head cabbages, Tomatoes
Type: not reported
Variety: Kinkei 201, Patio
Botanical name: *Brassica oleracea, Lycopersicon esculentum*
Crop parts(s) or processed
Commodity: leaves
Sample size: Cabbage and tomato: 5 g

3. Soil: moist compost (Kureha Chemical Co., Ltd.)

B. STUDY DESIGN

1. Test procedure

Metabolism studies were conducted using the separated leaf cell suspension of cabbage (*Brassica oleracea*) and tomato (*Lycopersicon esculentum*) with phenolic, alcoholic, anilinic, and carboxylic compounds, which are the primary metabolites from various kinds of agrochemicals. The ^{14}C-labeled primary metabolites 4-cyanophenol **(1)**, 3-phenoxybenzoic acid **(2)**, 3-phenoxybenzyl alcohol **(3)**, 3,5-dichloroaniline **(4)** and (1RS)-trans-2,2-dimethyl-3-(2-methylprop-1-enyl)cyclopropanecarboxylic acid **(5)** are shown from Figure 6.2.1-3 to Figure 6.2.1-7.
Seeds of cabbage (*B. oleracea*) and tomato (*L. esculentum*) were sown in 50 mL plastic pots containing a moist compost and grown until third- to fourth-leaf stage in a temperature controlled cabinet at 25 °C for day temperature and 22 °C for night temperature. Light with an intensity of 19500 lx at the level of primary leaves was supplied by a combination of fluorescent and incandescent lights with a 16 h light and 8 h dark sequence. Irrigation was appropriately conducted until sampling for approximately a month. Five grams of third and fourth-leaves in fresh weight were used for the experiments.
Sampled leaves were immersed in 80% ethanol (v/v) for 30 s, sterilized by dipping into a 0.5% sodium hypochlorite solution for 10 min, and rinsed three times with sterilized deionized water. The leaves were then transferred into a homogenizer cup filled with 120 mL of Murashige-Skoog medium, cut into small pieces and homogenized. Prior to the experiment, the osmotic pressure and pH of the MS medium were adjusted to 0.3-0.4 M and 6.5, respectively, and the prepared medium was sterilized by autoclaving. 20 mL portions of the leaf homogenate were divided into 100 mL Erlenmeyer flasks, and 1% of Macerozyme R-10 was added to each. The methanol dose solutions of ^{14}C-**1-5** were individually prepared by isotopically diluting them with corresponding non-radiolabeled reference standards to give the specific activity of approximately
4.3 kBq/µg. Each of the dose solution was spiked into the leaf suspension medium. Sampling was conducted at 1, 2, and 4 days of exposure.

2. Description of analytical procedures

The incubated samples were first divided into leaf cells and culture medium by filtration and were stored in a freezer (<-20 °C) before analyses. The leaf cells were extracted with acetone/water (4:1, v/v). The homogenate was filtered and the residue on the filter was extracted. The culture medium was partitioned three times with a 3-fold volume of ethyl acetate. Aliquots of the plant extracts as well as the organic and water layers from culture medium were radioassayed by LSC. The plant residues were air-dried in open vessels at room temperature for 1 week, and subsamples of the dried residues were subjected to combustion analysis to determine the remaining radioactivity.
For the purpose of isolating unknown metabolites for spectroscopic analyses, the plant extracts and the organic layer of the culture medium were individually subjected to the preparative purification by a solid-phase absorbent cartridge. The chemical identities of the secondary metabolites were determined by various spectrometric analyses (LC-MS, LC-MS/MS, and NMR) and/or HPLC cochromatography with the synthetic reference standards.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs) and EXTRACTION

The recoveries of the ^{14}C labelled compounds **1-5** from the test system after 1 day of incubation are shown in Table 6.2.1-8.

Table 6.2.1-8: Recoveries of the ^{14}C labelled compounds 1-5 from the test system after 1 day of incubation

Compound	Recovery of applied radioactivity (^{14}C) [%]
1	78.8
2	82.3
3	79.8
4	80.6
5	78.6

The unrecovered ^{14}C increased as the exposure period was extended, possibly due to azeotropic vaporization (data not shown). There were insignificant differences in the loss of ^{14}C from the test system among the test substances, although the Henry's law constants of **1-5** greatly varied by 3 orders. The distribution of ^{14}C within the test system after 1 day of exposure was examined in duplicate, and the result is shown in Table 6.2.1-9. The radioactivity taken up by cabbage leaf cell was estimated to be 36.2% TRR **(1)**, 46.3% TRR **(2)**, 35.9% TRR **(3)**, 50.8% TRR **(4)** and 47.2% TRR **(5)** by combining extractable and unextractable ^{14}C. For tomato leaf cell, an increase in rate of the ^{14}C taken up was observed compared to the one in cabbage, as 80.8% TRR **(1)**, 79.7% TRR **(2)**, 91.4% TRR **(3)**, 84.3% TRR **(4)**, and 86.6% TRR **(5)**. The unextractable ^{14}C for compound **1-5** amounted to 3.0-5.4% TRR in cabbage and 2.4-6.9% TRR in tomato.

Table 6.2.1-9: ^{14}C distribution of compound 1-5 in the cell suspension system

Total radioactive residues (TRR) [%]					
Compound	**1**	**2**	**3**	**4**	**5**
Cabbage

B. CHARACTERIZATION AND IDENTIFICATION OF RESIDUES

1. Identification, characterization and quantitation of extractable residues

The formation and decline of metabolites were examined in detail for the compound [^{14}C]-5 using the cabbage leaf cell suspension with exposure periods of 1, 2, and 4 days. The metabolic distribution reached a plateau within 1 day, and approximately 100% of the radioactivity detected in the cabbage leaf cell was the malonylglucose conjugate **(15)** of compound **5**. On the basis of these data, the incubation period in the study examining metabolic profiles of the compounds [^{14}C]-**1-5** was determined to be 1 day after treatment. The metabolic distribution in the extract of leaf cells is shown in Table 6.2.1-10. In general, the test compounds were extensively metabolized in the leaf cells of cabbage as compared with tomato cells. In cabbage, the glucose conjugate **(6)** was the only metabolite from compound **(1)** and amounted to 27.6% TRR with the remaining radioactivity (3.2% TRR) being unchanged compound **(1)**. Both compounds **(3)** and **(4)** were fully transformed within 1 day of exposure as none of the corresponding test compounds remained in the extract of the leaf cells. The metabolites of compound **(3)** were glucoside **(11)** and malonylglucoside **(12)** conjugates, each at 4.6% and 27.7% TRR, and compound **(4)** was metabolized to glucoside **(13)** and glutamate **(14)** conjugates at 23.7% and 16.3% TRR, respectively. In the case of compounds **(2)** and **(5)**, differences were observed in the metabolic profiles, such as compound **(2)** being transformed to three major metabolites, glucoside **(8)** and malate **(9)** conjugates and a hydroxylated free form **(10)** at 6.6%, 18.4% and 2.4% TRR, respectively, whereas compound **(5)** was solely metabolized to its malonylglucoside conjugate **(15)** at 43.3% TRR. Some of the metabolites derived from compounds **(1)** and **(2)** were detected in the culture medium. The metabolic distribution of compound **(1)** in the medium of cabbage was 9.4% TRR for metabolite **(6)** and 7.4% TRR for metabolite **(7)**. In the case of compound **(2)**, metabolites **(8)**, **(9)**, and **(10)** were detected in the cabbage culture medium at 34.3%, 7.6% and 0.8% TRR, respectively. With respect to tomato plant, compounds **(1)**, **(2)** and **(4)** were transformed to their corresponding glucose conjugates at the levels of 9.1% TRR **(6)**, 2.2% TRR **(8)**, and 15.1% TRR **(13)**, respectively, within the total test system. No transformation products were observed for compounds **(3)** or **(5)**.

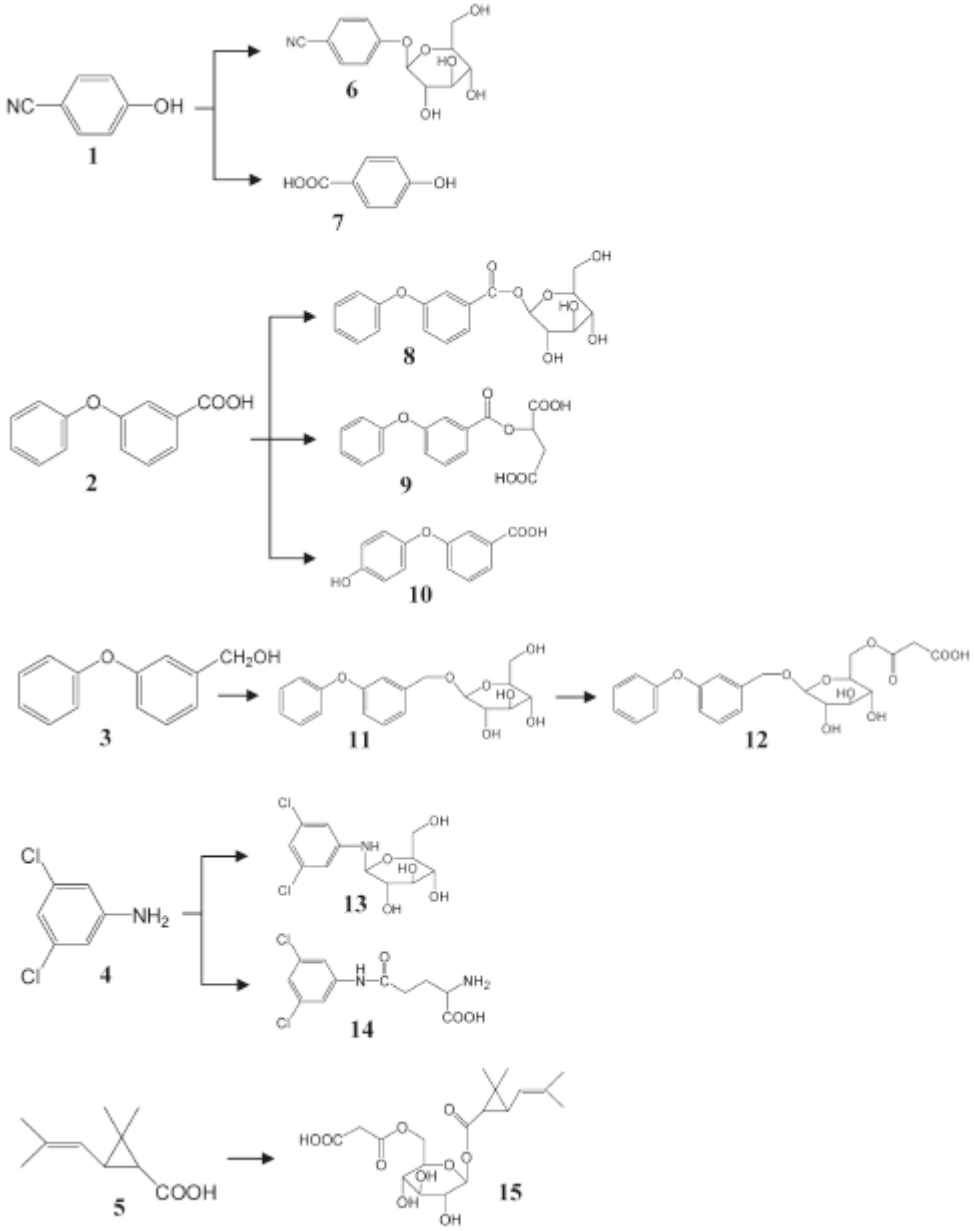
2. Proposed metabolic pathway

The chemical identities of the secondary metabolites were determined by various spectrometric analyses (LC-MS, LC-MS/MS, and NMR) and/or HPLC cochromatography with the synthetic reference standards. On the basis of these identifications, the metabolic pathways of the compounds 1-5 are summarized in Figure 6.2.1-8.

Figure 6.2.1-8: Proposed metabolic pathways of compounds 1-5



III. CONCLUSION

After 1 day of incubation, the metabolites were extensively transformed in cabbage, whereas they were scarcely metabolized in tomato. The major metabolic pathways were the phase II reactions leading to a number of conjugates such as glucoside/malonylglucoside of compounds (1)-(5), malate of compound (2) and glutamate of compound (4). The oxidation of compounds (1) and (2) was observed as a minor reaction to produce 4-hydroxybezoic acid and 3-(4-hydroxyphenoxy)benzoic acid.

In conclusion, the results presented in the study substantiate the view that xenobiotic metabolism conducted using the separated leaf cell suspension is a useful adjunct to the conventional whole plant approach. The study has shown that the oxidative reactions and/or conjugation reactions observed in vivo were also found in the separated leaf cell suspension for compounds 1-5. Furthermore, the species difference detected in plants was considered to be reflected in this test system, with respect to both the nature of phase I and phase II metabolites formed and the amount of parent compounds remained. Especially, the cabbage leaf cell suspension clearly demonstrated the high efficiency of xenobiotic catabolism showing quantitative transformation of the substrates within a day. From this fact, it can be assumed that this system will be an effective tool for the research on metabolic features in whole plant.

CA 6.2.2 Poultry

In the framework of the original inclusion into Annex I according to Directive 91/414/EEC a metabolism study in laying hens (AL-440-021) was peer-reviewed. The characteristics of this study are summarized in Table 6.2.2-1.

Table 6.2.2-1: Metabolism study in laying hen previously available

Group	Species	Label position	No of animal	Application details		Sample details		Year	DocID
				Rate (mg/kg bw per d)	Duration (days)	Commodity	Time		
Laying poultry	Hens	Benzyl ring-U-^{14}C Cycloprop ane-l-^{14}C	32 (4 groups of 8 hens)	7.5-7.75 (low dose) 17.13-18.01 (high dose)	14	Eggs	Daily during the dosing period	2001	AL-440-021
						Excreta			
						Tissues	22 h after last administration		

In laying hens, the major part of the radioactivity was excreted with urine (up to 93% of the total administered dose). The highest residue levels were found in liver and fat (skin+abdominal) both for the 2 dosing groups. Extractability of the residues with various solvents and after enzymatic digestion exceeded 90% of the TRR in the edible tissues and eggs.
Residue levels in eggs sampled at the high dose levels reached a plateau after 6 days (0.092 mg/kg) and 8 days (0.053 mg/kg) respectively for cyclopropane and benzyl labelling forms at the high dose. The major part of the extractable residues could be identified (at least 75% of the TRR except in liver for which the identification rate was rather low and ranged between 13% and 43% of the TRR). Characterization and identification of the radioactive residues in the different matrices revealed that parent compound was the predominant component in fat (skin+abdominal) and in eggs (at least 70% of the TRR). In liver, the metabolite cis-DCVA was recovered as the major metabolite for the cyclopropane labelling form (30% of the TRR) while a major amount of the radioactive residues remained unidentified (35 to 55% of the TRR).
Interconversion of cis and trans isomers didn't occur neither in the eggs nor tissues.

In order to confirm the results as shown above and to further clarify the remaining unidentified amounts with state-of-the-art analytic technology, it was decided to conduct a new hen metabolism study according to current guideline requirements.

Report:	CA 6.2.2/1 [redacted] 2014a The Metabolism of [14C]-Reg. No. 4078193 (BAS 310 I) in Laying Hens 2014/1140293
Guidelines:	EPA 860.1300: EPA Residue Chemistry Test Guidelines,EPA 860.1300: Nature of the Residue in Plants Livestock,EPA 860.1000: EPA Residue Chemistry Test Guidelines,EPA 860.1000: Background - PMRA Section 97.2 (Canada): Residue Chemistry Guidelines: Plants and Lifestock (June 1997), JMAFF 59 NohSan No 4200,BBA IV 3-2,EEC 7028/VI/95 rev. 3 Appendix A (EU): Metabolism and distribution in plants (draft of 22 July 1997)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Description:	Alpha-cypermethrin (BAS 310 I)
Lot/Batch #:	775-0401 (benzyl-U-^{14}C) 1025-1034 (phenoxy-1,2,3,4,5,6-^{13}C) (for benzyl blend) 986-1046 (cyclopropane-1-^{14}C) 990-1024 (cyclopropane-1-^{13}C) L80-24 (unlabeled)
Purity:	96.1% (radiochemical), 4.94 MBq/mg (benzyl-U-^{14}C) 95.1% (phenoxy-1,2,3,4,5,6-^{13}C) 93.6% (radiochemical), 4.9 MBq/mg (cyclopropane-1-^{14}C) 97.7% (cyclopropane-1-^{13}C) 99.4% (unlabeled)
CAS#:	67375-30-8
Development code:	4078193
Stability of test compound:	The test item was stable for the test period

2. Test Animals

Species:	Hen
Variety:	Hy-line Brown
Gender:	Female
Age:	67-68 weeks
Weight at dosing:	1.714-2.317 kg
Number of animals:	20 (10 per label)
Acclimation period:	Min. 11 days
Diet:	Non-medicated feed ("Layer Mash"), *ad libitum*
Water:	Water, *ad libitum*
Housing:	Individually in metabolic cages

Environmental conditions -
Temperature: 17-24°C
Humidity: 12-60% (The low humidity results recorded are of no welfare concern to the birds as they had ad libitum access to water)
Photoperiod: 16 h light / 8 h dark

B. STUDY DESIGN AND METHODS

1. Dosing regime

Oral:
Amount of dose: 12 mg/kg feed/day (nominal)
Food consumption: 25-186 g food (dry weight)/animal/day
Vehicle: Gelatin capsule by oral gavage
Timing: Once daily
Duration: 14 days

2. Sample collection

Egg collection: Twice daily
Excreta collection: Daily
Interval from last dose to sacrifice: 6-7 h
Tissues harvested & analyzed: Eggs, liver, breast / thigh muscle, fat

3. Test system

The metabolism and distribution of alpha-cypermethrin was investigated in ten laying hens per label following a repeated oral administration of benzyl-U-^{14}C- or cyclopropane-1-^{14}C-BAS 310 I at a dose level of 12 mg/kg feed for 14 consecutive days. The test item was prepared in gelatin capsules and administered orally by gavage. The mean daily dose administered was 14.8 (benzyl label) and 14.0 mg/kg food consumed (dry weight equivalent) (cyclopropane label). The values exclude the final dose as it is not representative of a full 24 h cycle. Details of the study outline are summarized in Table 6.2.2-2.

Table 6.2.2-2: Dosing of laying hens with ^{14}C-alpha-cypermethrin

Animal	Treatment days	Nominal daily dose	Actual daily dose (mean)	
		mg/kg feed intake	mg/kg feed intake[1]	mg/kg bw[2]
Benzyl-U-^{14}C label				
11-20	14	12	13.0-17.8	0.81-1.04
Cyclopropane-1-^{14}C label				
1-10	14	12	12.4-16.5	0.74-1.00

1 Mean excludes day 14
2 Based on mean body weight on study days 2, 4 and 14 for animals 1-10 and on study days 1 and 14 for animals 11-20 as well as on mean total test item in capsule (1.82 mg for animals 11-20 and 1.73 mg for animals 1-10)

4. Sampling and Storage

During the dosing period eggs were collected at least twice daily (am and pm). Eggs collected in the afternoon of each day during the dosing period were stored in a fridge set to maintain a temperature of 4°C prior to analysis, eggs collected in the morning were immediately analyzed.
Excreta was collected prior to the first dose administration and at 24 h intervals thereafter until the sacrifice time. After processing and analysis, subsamples of excreta were taken and frozen at -20°C. For each label samples were pooled for further analysis on a daily basis.
Approximately 6-7 h after administration of the final dose, the hens were killed. The carcasses were plucked and the following samples removed: liver, omental fat, renal fat, subcutaneous fat with skin attached, breast muscle, thigh muscle, whole blood, partially formed eggs, GI tract and carcass. Any whole eggs still in the oviduct at sacrifice were collected. The eggs with shell collected from the oviduct were combined with the Day 14 eggs. All other partially formed eggs present in the carcass were retained separately for each hen and analyzed only for determination of the total radioactive residue. The carcasses were retained but analysis was not required.

5. Description of analytical methods

For the determination of the measured TRR, homogenized material (tissues) was combusted by means of a sample oxidizer before LSC measurement. For samples not requiring combustion (eggs), radioactivity was directly determined by mixing with a suitable scintillation fluid and LSC analysis.
The homogenized samples of both labels (egg yolk, egg white (cyclopropane label only), liver, breast muscle and thigh muscle) were extracted with acetonitrile and water. The acetonitrile extract was thereafter extracted with isohexane (egg yolk, liver, breast muscle and thigh muscle), which resulted in an acetonitrile phase and an isohexane phase. Fat of both labels was extracted similarly, but with a mixture of acetonitrile and isohexane. The corresponding phases were separated after extraction.

The extracts and / or processed samples of the extracts were analyzed with HPLC in order to characterize, identify and quantify radioactive residues. Identification of metabolites was mainly based on co-chromatography experiments. An additional metabolite was identified via HPLC-MS of a purified water extract of liver (cyclopropane label). Further components were isolated and characterized by incubation with enzymes (e.g. pancreatin).

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

In the analytical phase of the study, the TRR was calculated by summarizing the extractable radioactive residue (ERR) and the residual radioactive residue after solvent extraction (RRR). The calculated TRR was then set to 100%. The amounts of radioactivity which were detected in matrices relevant for the metabolism investigations are summarized in Table 6.2.2-3. The highest concentrations were detected in liver (benzyl label: 0.279 mg/kg and cyclopropane label: 0.383 mg/kg). The concentrations in egg yolk (benzyl label: 0.141 mg/kg and cyclopropane label: 0.149 mg/kg) and fat (benzyl label: 0.150 mg/kg and cyclopropane label: 0.084 mg/kg) were somewhat lower compared to liver. The concentrations in egg white, breast and thigh muscle were significantly lower compared to the other matrices (from 0.008 mg/kg to 0.022 mg/kg; for egg white of the benzyl label the TRR calculated was not determined, the TRR measured was 0.004 mg/kg). Overall, the amount of radioactive residues in corresponding matrices of the benzyl label and the cyclopropane label was comparable.
The TRR of all matrices was also measured by combustion analysis. For all matrices, the TRR measured was similar to the TRR calculated.

Table 6.2.2-3: Total radioactive residues in edible matrices after dosing of laying hens with [benzyl-U-^{14}C]- or [cyclopropane-1-^{14}C]-alpha-cypermethrin

Matrix	TRR [mg/kg]			
	measured	calculated	measured	calculated
	Benzyl-U-^{14}C label		Cyclopropane-1-^{14}C label	
Egg yolk	0.152	0.141	0.163	0.149
Egg white	0.004	n.r.	0.009	0.008
Liver	0.288	0.279	0.369	0.383
Breast muscle	0.007	0.009	0.010	0.011
Thigh muscle	0.021	0.022	0.017	0.019
Fat	0.149	0.150	0.082	0.084

TRR: Total radioactive residue
Calculated: Sum of ERR + RRR
n.r. Not reported

B. EXTRACTION OF RESIDUES

Egg white of the benzyl label was not extracted, due to the low residue level. For all other matrices the major part of radioactivity was recovered for both labels in the acetonitrile extract and the acetonitrile phase, respectively. Thereby, the residues ranged from 38.7% (liver, benzyl label) to 84.5% of the TRR (thigh muscle, benzyl label). The amount of radioactivity in acetonitrile extracts / phases of corresponding matrices of the benzyl label and the cyclopropane label was largely comparable.

For egg yolk significant amounts of radioactivity were also recovered in the isohexane phase (benzyl label: 18.5% TRR and cyclopropane label: 23.3% TRR), which originated from the acetonitrile extract. For fat, which was extracted simultaneously with acetonitrile and isohexane, the residues in the isohexane phase (benzyl label: 41.4% TRR and cyclopropane label: 48.0% TRR) were comparable to the residues in the acetonitrile phase (benzyl label: 55.5% TRR and cyclopropane label: 50.3% TRR).

In the water extracts of egg yolk (both labels), egg white (cyclopropane label) and liver (both labels) the residues ranged from 13.1% to 25.9% of the TRR. The amount of radioactivity in the water extracts of breast and thigh muscle of both labels was lower (from 6.0% to 12.0% TRR). The amount of radioactivity in water extracts of corresponding matrices of the benzyl label and the cyclopropane label was comparable. Overall, the ERR of both labels ranged from 57.6% (egg white, benzyl label) to 99.1% TRR (fat, benzyl label).

Table 6.2.2-4: Extractability of edible matrices with solvents (acetonitrile, isohexane, water) after dosing of laying hens with [benzyl-U-^{14}C]- or [cyclopropane-1-^{14}C]-alpha-cypermethrin

Matrix	TRR (calculated) mg/kg	Solvent extract (ERR)		RRR

TRR: Total radioactive residue (sum of ERR + RRR)
ERR Extractable radioactive residue (solvents: acetonitrile, isohexane, water)
RRR: Residual radioactive residue after solvent extraction (solvents: acetonitrile, isohexane, water)

C. IDENTIFICATION AND CHARACTERIZATION OF RESIDUES

A summary of all identified metabolites and their distribution in egg, muscle, fat and liver is given in Table 6.2.2-5 and Table 6.2.2-6.

The unchanged parent compound **BAS 310 I** was identified in all examined matrices (egg yolk and egg white, liver, breast muscle, thigh muscle and fat) of both labels (aside from liver of the cyclopropane label). Thereby, BAS 310 I was the most abundant component in egg yolk (benzyl: 0.059 mg/kg or 41.6% TRR, cyclopropane: 0.051 mg/kg or 34.3% TRR), thigh muscle (benzyl: 0.013 mg/kg or 60.5% TRR, cyclopropane: 0.004 mg/kg or 20.9% TRR) and fat (benzyl: 0.094 mg/kg or 62.6% TRR, cyclopropane: 0.038 mg/kg or 45.4% TRR) of both labels. Moreover, BAS 310 I was identified in egg white, liver and breast muscle.
Additionally metabolites M310I019, M310I001 and M310I003 were identified, which were all label-specific. **M310I019** (3-hydroxybenzoic acid) was identified in liver of the benzyl label (0.043 mg/kg or 15.2% TRR). **M310I001** corresponds to the cyclopropane moiety of BAS 310 I after hydrolysis of the ester bond. M310I001 was identified in all matrices of the cyclopropane label (aside from fat) and was the most abundant component in egg white (0.002 mg/kg or 18.1% TRR), liver (0.221 mg/kg or 57.7% TRR) and breast muscle (0.002 mg/kg or 23.7% TRR). In thigh muscle of the cyclopropane label the concentration of M310I001 was similar to that of BAS 310 I. In egg yolk of the cyclopropane label only small amounts of M310I001 were present. Metabolite **M310I003** results from hydroxylation of a methyl group of M310I001. M310I003 was identified in the cyclopropane label of egg white (0.001 mg/kg or 9.2% TRR) and liver (0.011 mg/kg or 2.9% TRR).
Aside from the identified compounds, three components were characterized in some matrices of both labels. One peak corresponds probably to a component with the molecular formula $C_{21}H_{18}Cl_2O_4$. The other two compounds are probably conjugates of phase I metabolites of BAS 310 I. Overall, from 0.006 mg/kg or 53.4% TRR (breast muscle, cyclopropane label) up to 0.143 mg/kg or 95.7% TRR (fat, benzyl label) of the ERR were identified and characterized. If applicable, the RRR was further analyzed via solubilization with enzymes, HPLC, partition experiments and / or SPE fractionation. Thereby, from 0.001 mg/kg or 5.7% TRR (thigh muscle, benzyl label) up to 0.004 mg/kg or 35.7% TRR (breast muscle, cyclopropane label) were characterized.

1. Metabolic pathway

The proposed metabolic pathway of BAS 310 I in hen is shown in Table 6.2.2-1. Hydrolysis of the ester bond of BAS 310 I results in a cyclopropane and a phenoxybenzyl moiety of the molecule. The cyclopropane moiety corresponds to metabolite M310I001. Hydroxylation of a methyl group of M310I001 yields metabolite M310I003. Cleavage of the nitrile group of the phenoxybenzyl moiety and oxidation yields the postulated intermediate M310I011, which was identified in the rat metabolism study. Cleavage of M310I011 yields metabolite M310I019 (3-Hydroxybenzoic acid).

2. Enantiomer ratio

The parent compound BAS 310 I was isolated from egg yolk and fat extracts in order to determine the enantiomer ratio. For both labels, the enantiomer ratio of BAS 310 I in egg yolk and fat was approximately 1:1, similar to the ratio of the application solutions.

3. Storage stability

All matrices were extracted within a maximum of 120 days after sampling. Quantitative analyses of the acetonitrile phases / extracts and the acetone supernatants of the water extracts were carried out within a maximum of 147 days after sampling, aside from the liver acetonitrile phase of the benzyl label (504 days). However, an early analysis of the same liver acetonitrile phase led to a similar metabolite pattern as the late analysis. Hence, due to timely extraction and analysis of the matrices no additional storage stability investigations were necessary.

III. CONCLUSION

The highest total radioactive residue (TRR) was detected in liver (benzyl: 0.279 mg/kg and cyclopropane: 0.383 mg/kg). The concentrations in egg yolk and fat were somewhat lower compared to liver. The concentrations in egg white, breast and thigh muscle were significantly lower compared to the other matrices (below or equal to 0.022 mg/kg). Overall, the amount of radioactive residues in corresponding matrices of the benzyl label and the cyclopropane label was comparable.

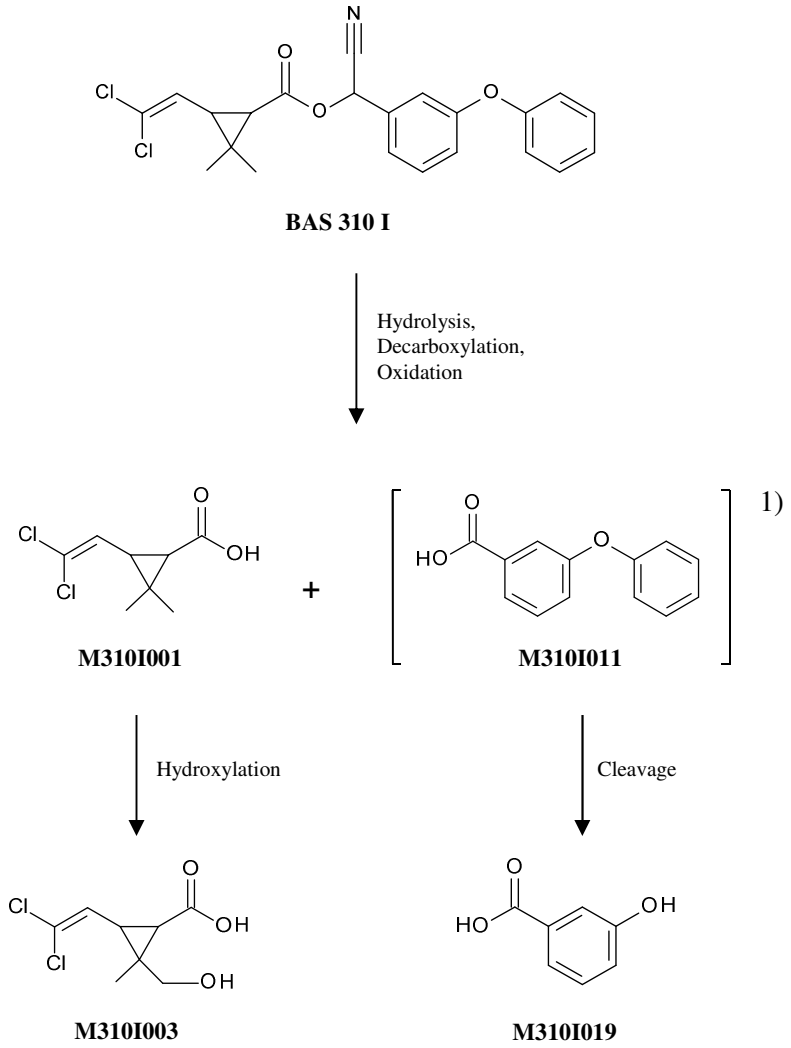
For all examined matrices, the major part of radioactivity was recovered for both labels in the acetonitrile extract and the acetonitrile phase, respectively. Thereby, the acetonitrile residues ranged from 38.7% (Liver, benzyl label) to 84.5% of the TRR (thigh muscle, benzyl label). For fat, which was extracted simultaneously with acetonitrile and isohexane, the residues in the isohexane phase were comparable to the residues in the acetonitrile phase. The amount of radioactivity in isohexane, acetonitrile and water extracts / phases of corresponding matrices of the benzyl label and the cyclopropane label was largely comparable. Overall, the ERR of both labels ranged from 57.6% (egg white, benzyl label) to 99.1% TRR (fat, benzyl label).

The unchanged parent compound BAS 310 I was identified in all examined matrices (egg yolk and egg white, liver, breast muscle, thigh muscle and fat) of both labels (aside from liver of the cyclopropane label). Thereby, BAS 310 I was the most abundant component in egg yolk (benzyl: 0.059 mg/kg or 41.6% TRR, cyclopropane: 0.051 mg/kg or 34.3% TRR), thigh muscle (benzyl: 0.013 mg/kg or 60.5% TRR, cyclopropane: 0.004 mg/kg or 20.9% TRR) and fat (benzyl: 0.094 mg/kg or 62.6% TRR, cyclopropane: 0.038 mg/kg or 45.4%TRR) of both labels. Moreover, BAS 310 I was identified in egg white, liver and breast muscle. Additionally metabolites M310I019, M310I001 and M310I003 were identified, which were all label-specific. M310I019 (3-hydroxybenzoic acid) was identified in liver of the benzyl label (0.043 mg/kg or 15.2% TRR). M310I001 corresponds to the cyclopropane moiety of BAS 310 I after hydrolysis of the ester bond. M310I001 was identified in all matrices of the cyclopropane label (aside from fat) and was the most abundant component in egg white (0.002 mg/kg or 18.1% TRR), liver (0.221 mg/kg or 57.7% TRR) and breast muscle (0.002 mg/kg or 23.7% TRR). In thigh muscle of the cyclopropane label the concentration of M310I001 was similar to that of BAS 310 I. In egg yolk of the cyclopropane label only small amounts of M310I001 were present. Metabolite M310I003 results from hydroxylation of a methyl group of M310I001. M310I003 was identified in the cyclopropane label of egg white (0.001 mg/kg or 9.2% TRR) and liver (0.011 mg/kg or 2.9 % TRR).

The parent compound BAS 310 I was also isolated from egg yolk and fat extracts in order to determine the enantiomer ratio. For both labels, the enantiomer ratio of BAS 310 I in egg yolk and fat was approximately 1:1, similar to the ratio of the application solutions.

Aside from the identified compounds, three components were characterized in some matrices of both labels. One peak corresponds probably to a component with the molecular formula $C_{21}H_{18}Cl_2O_4$. The other two compounds are probably conjugates of phase I metabolites of BAS 310 I. Overall, from 0.006 mg/kg or 53.4% TRR (breast muscle, cyclopropane label) up to 0.143 mg/kg or 95.7% TRR (fat, benzyl label) of the ERR were identified and characterized. If applicable, the RRR was further analyzed via solubilization with enzymes, HPLC, partition experiments and / or SPE fractionation. Thereby, from 0.001 mg/kg or 5.7% TRR (thigh muscle, benzyl label) up to 0.004 mg/kg or 35.7% TRR (breast muscle, cyclopropane label) were characterized.

Figure 6.2.2-1: Proposed metabolic pathway of BAS 310 I in hen



1) postulated intermediate (not detected)

CA 6.2.3 Lactating ruminants

In the framework of the original inclusion into Annex I according to Directive 91/414/EEC a metabolism study in lactating cow was peer-reviewed. The characteristics of this study are summarized in Table 6.2.3-1.

Table 6.2.3-1: Metabolism study in lactating cow previously available

Group	Species	Label position	No of animal	Application details		Sample details		Year	DocID
				Rate (mg/kg bw per d)	Dura-tion (days)	Commo-dity	Time		
Lactating ruminants	Cow	Benzyl-U-^{14}C	1 treated 1 control	0.49; overall calculated dietary concentration 19 mg/kg	4 days	Urine (excreted)	at 24 h intervals	1994	AL-440-014
						Faeces	at 24 h intervals		
						Milk	daily at ca. 09:00 and 15:00		
						Whole blood Plasma Liver Kidney Bile Fat Muscle Urine (bladder)	6 h after administration of last dose		

1 based on 250 mg/day and bw 510 kg

^{14}C-labelled alpha-cypermethrin was administered orally to a cow (overall calculated dietary concentration 19 mg/kg) via twice daily doses added to the diet. Whereas muscle, fat and milk mainly contained a single compound with similar chromatographic properties to alpha-cypermethrin (muscle 85%, fat 91%, milk 97%), the liver extract contained at least 8 metabolites with a broad range of polarities, one component (±16%) had similar chromatographic properties to those of alpha-cypermethrin. In urine, the 2 major components had identical chromatographic properties to N-(3-phenoxybenzoyl)glutamic acid and N-(3-phenoxybenzoyl)glycine, respectively. A minor component had identical chromatographic properties (HPLC) to 3-phenoxybenzoic acid (3%).

No metabolic pathway could be established as only the parent compound and some conjugates were identified. No further investigation was carried out to identify and quantify the other metabolites.

In order to further clarify the metabolic pathway in lactating ruminants with state-of-the-art analytic technology, it was decided to conduct a new goat metabolism study according to current guideline requirements.

Report:	CA 6.2.3/1 [redacted] 2014a The Metabolism of ^{14}C Reg. No. 4078193 (BAS 310 I) in Lactating Goats 2014/1083330
Guidelines:	EPA 860.1300: Nature of the Residue in Plants Livestock,EPA 860.1000,OECD Test Guideline 503 - Metabolism in livestock,EEC 91/414 (7030(VI/95 Rev. 3)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Description:	Alpha-cypermethrin (BAS 310 I)
Lot/Batch #:	775-0401 (benzyl-U-^{14}C) 1025-1034 (phenoxy-1,2,3,4,5,6-^{13}C) (for benzyl blend) 986-2015 (cyclopropane-1-^{14}C) 990-1025 (cyclopropane-1-^{13}C) L80-24 (unlabeled)
Purity:	96.1% (radiochemical), 4.94 MBq/mg (benzyl-U-^{14}C) 95.1% (phenoxy-1,2,3,4,5,6-^{13}C) 98.9% (radiochemical), 4.7 MBq/mg (cyclopropane-1-^{14}C) 97.7% (cyclopropane-1-^{13}C) 99.4% (unlabeled)
CAS#:	67375-30-8
Development code:	4078193
Stability of test compound:	The test item was stable for the test period

2. Test Animals

Species:	Goat
Variety:	“Saanen cross Toggenburg” or pure "Saanan
Gender:	Female
Age:	Not reported
Weight at dosing:	40.0-68.5 kg
Number of animals:	4 (2 per label)
Acclimation period:	20 days
Diet:	2 x 0.5 kg non-medicated supplementary concentrate + hay *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Metabolic cages
Environmental conditions	
Temperature:	17-23°C
Humidity:	17-89%
Photoperiod:	12 h light / 12 h dark

B. STUDY DESIGN AND METHODS

1. Dosing regime

Oral:

Amount of dose:	12 mg/kg feed/day
Food consumption:	1.087-2.117 kg/animal/day
Vehicle:	Gelatin capsule by oral gavage
Timing:	Once daily
Duration:	7 days

2. Sample collection

Milk collection:	Twice daily
Urine and feces collection:	Daily
Interval from last dose to sacrifice:	5-8 h
Tissues harvested & analyzed:	Urine, feces, milk, bile, liver, kidney, muscle, fat

3. Test system

The metabolism and distribution of alpha-cypermethrin was investigated in two lactating goats per label following a repeated oral administration of benzyl-U-^{14}C-BAS 310 I or cyclopropane-1-^{14}C-BAS 310 I at a dose level of 12 mg/kg feed for seven consecutive days. By mistake within the preparation of the application solution of the cyclopropane label for the ^{13}C-labeled BAS 310 I, instead of alpha-cypermethrin (comprising the isomers (S)-cyano-(1R,3R) and (R)-cyano-(1S,3S)) a different pair of cis isomers of cypermethrin (comprising the isomers (S)-cyano-(1S,3S) and (R)-cyano-(1R,3R)) was used. Therefore, for the cyclopropane label, the actual dose of the applied alpha-cypermethrin was less than the target dose, and amounted to 8.55 mg/kg feed. This has no relevant impact on the results of the study. The test item was prepared in gelatin capsules and administered orally by gavage. Details of the study outline are summarized in Table 6.2.3-2.

Table 6.2.3-2: Dosing of lactating goats with ^{14}C-alpha-cypermethrin

Animal	Treatment days	Nominal daily dose	Actual daily dose		Sacrifice time after last dose (hours)
		mg/kg feed intake	mg/kg feed intake	mg/kg bw	
Benzyl-U-^{14}C label					
1+2	7	12	13.29-14.73	0.36-0.42	5
Cyclopropane-1-^{14}C label					
3+4	7	12	8.35-8.75	0.26-0.29	8

4. Sampling and storage

During the application period, aliquots of milk, urine and feces were taken for the determination of the radioactive residues twice daily for milk and daily for urine and feces. Tissues and organs (liver, kidney, muscle and fat samples) and bile were collected after animal sacrifice. The animals were killed approximately 5 h and 8 h after administration of the last dose at the time of the maximum residue concentration in plasma (t_{max}). All samples were stored at –18°C or below. Representative pool samples of urine and feces were combined for 24-144 h (benzyl label) and 24-156 h (cyclopropane label), respectively. A pool sample of milk was made for 55-96 h (cyclopropane label) and 103-127 h (benzyl and cyclopropane label). The pool samples of urine, feces and milk and tissue homogenates of liver, kidney, bile, muscle and fat were also analyzed for total radioactive residues.

5. Description of analytical methods

Aliquots of liquid samples (milk, urine) were directly analyzed after mixing with scintillation cocktail without additional treatment. Fat samples were treated with tissue solubilizer and bleached before mixing with scintillator and LSC measurement. The total radioactivity in solid samples (feces and tissues) was determined by combustion.
The homogenized feces and tissue samples of both labels were extracted with acetonitrile and water. Milk samples (103-127 h) were extracted with a mixture of acetonitrile and isohexane. Milk pool sample (55-96 h) of the cyclopropane label was extracted with acetonitrile. Fat samples were extracted with a mixture of acetonitrile and isohexane followed by extraction with water. The extracts were subsequently pooled and aliquots were taken for LSC measurement. The residues were combusted for determination of the radioactive residues.
The residues after solvent extraction of liver (both labels) and kidney (cyclopropane label) were further solubilized with pronase.
HPLC analysis was carried out for samples with a sufficient level of radioactivity. In some cases, residues after solvent extraction were further solubilized and investigated by HPLC. Identification and assignment of metabolites was based on HPLC-MS investigations of urine and a cleaned up bile sample (benzyl label), on co-chromatography experiments, comparison of the retention times and on comparison of metabolite patterns of the extracts /solubilizates investigated with those of reference items. The quantitation of the parent compound and its metabolites is generally based on the HPLC analyses. Another HPLC method was used for the determination of the isotope pattern.
For metabolite investigations, homogenized subsamples of feces, liver, kidney and muscle were extracted with acetonitrile and water. Subsamples of pooled milk were extracted with acetonitrile (55-96 h, cyclopropane label) or with a mixture of acetonitrile and isohexane (103-127 h, both labels). Fat samples were extracted with a mixture of acetonitrile and isohexane and subsequently with water.

II. RESULTS AND DISCUSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRs)

The total radioactive residues (TRR) in all matrices are summarized in Table 6.2.3-3. Rapid excretion of the radioactive residues was observed. Until sacrifice, the radioactive residues excreted via urine and feces amounted to 72.9% (benzyl label) and 74.3% (cyclopropane label) of the total radioactivity administered.

The total radioactive residues (TRR) determined in pooled urine samples (24-144 h, benzyl label and 24-156 h, cyclopropane label) of goats treated with BAS 310 I were 1.055 mg/kg (benzyl label) and 10.903 mg/kg (cyclopropane label). In feces, 7.635 mg/kg and 10.779 mg/kg were found for the benzyl and the cyclopropane label, respectively.

The total radioactive residues measured in edible tissues and organs of the benzyl and cyclopropane label were 0.086 mg/kg and 0.489 mg/kg for liver and 0.058 mg/kg and 0.345 mg/kg for kidney. For the benzyl label, samples of omental, renal and subcutaneous fat were analyzed separately and radioactive residues amounted to 0.024 mg/kg, 0.031 mg/kg and 0.011 mg/kg, respectively. For the cyclopropane label composite fat was analyzed for both of the goats separately and radioactive residues amounted to 0.049 mg/kg and 0.141 mg/kg, respectively. Residue levels detected in muscle were 0.004 mg/kg for the benzyl label and 0.029 mg/kg for the cyclopropane label. In the pooled samples of milk, residue levels of 0.010 mg/kg (103-127 h, benzyl label), 0.053 mg/kg (55-96 h, cyclopropane label) and 0.044 mg/kg (103-127 h, cyclopropane label) were found. Bile contained 0.606 mg/kg (benzyl label) and 2.290 mg/kg (cyclopropane label). Overall milk, muscle and fat showed low residue levels.

Table 6.2.3-3: Total radioactive residues in edible matrices and excreta after dosing of lactating goats with [benzyl-U-^{14}C]- or [cyclopropane-1-^{14}C]-alpha-cypermethrin

Matrix	TRR [mg/kg]

TRR: Total radioactive residue (sum of ERR + RRR)
1 Milk pool sample 103-127 h
2 Total of urine and feces pool samples 24-156 h
3 Milk pool sample 55-96 h

B. EXTRACTION OF RESIDUES

The extractability was generally high and the portions of extractable radioactive residues (ERR) were equal to or above 89.9% TRR. Only for liver (both labels), kidney (cyclopropane label), and muscle (benzyl label), somewhat lower portions of radioactive residues were extracted by solvent extraction (61.1-85.4% TRR).

For most extractions, the major part of radioactive residues was found in the acetonitrile extract, while lower amounts of radioactive residues were detected in the isohexane phase after partition (4.5-11.9% TRR). Only for subcutaneous fat of the benzyl label a somewhat higher portion was in the isohexane phase (23.6% TRR). Extraction of liver and kidney yielded also some amounts of radioactive residues in the water extracts (18.4-36.3% TRR).

Due to the very low amounts of residual radioactive residues (RRR) in milk, muscle and fat (≤0.005 mg/kg), the residues after solvent extraction were not further investigated. Additional solubilization was performed the case of liver (both labels) and kidney (cyclopropane label). The respective residues after solvent extraction (RRR) were incubated with pronase, which solubilized additional 20.3% TRR from liver of the benzyl label, 38.9% TRR from liver of the cyclopropane label and 14.0% TRR from kidney of the cyclopropane label.

Table 6.2.3-4: Extractability of edible matrices and feces with solvents (acetonitrile, isohexane, water) after dosing of lactating goats with [benzyl-U-^{14}C]- or [cyclopropane-1-^{14}C]-alpha-cypermethrin

TRR: Total radioactive residue (sum of ERR + RRR)
ERR: Extractable radioactive residue (solvents: acetonitrile, isohexane, water)
RRR: Residual radioactive residue after solvent extraction

C. IDENTIFICATION AND CHARACTERIZATION OF RESIDUES

A summary of all identified metabolites and their distribution in excreta, bile, milk, muscle, fat, liver, and kidney is given in Table 6.2.3-5 to Table 6.2.3-8.

The unchanged parent compound was the main constituent in extracts from feces, milk, fat and muscle, representing 51.9-92.6% TRR. In addition BAS 310 I was found in liver and kidney of both labels at <5.0% TRR.

In detail, **BAS 310 I** was detected in extracts of the benzyl label at 7.069 mg/kg (92.6% TRR) in feces and at 0.005 mg/kg (51.9% TRR) in milk pooled from 103-127 h. The parent compound amounted to 0.019 mg/kg (77.3% TRR) in omental fat, 0.026 mg/kg (83.8% TRR) in renal fat and 0.009 mg/kg (74.5% TRR) in subcutaneous fat.
For the cyclopropane label BAS 310 I was likewise detected at 7.284 mg/kg (67.6% TRR) in feces, 0.043 mg/kg (80.5% TRR) in milk (55-96 h) and 0.033 mg/kg (74.0% TRR) in milk (103-127 h). In composite fat it was detected at 0.035 mg/kg (71.2% TRR) for goat 3 and at 0.127 mg/kg (89.8% TRR) for goat 4. BAS 310 I was furthermore detected at 0.019 mg/kg (65.6% TRR) in composite muscle.

In urine and kidney, high abundances were found for the label-specific metabolites **M310I010**, **M310I011** (benzyl label) and **M310I001**, **M310I003** and **M310I004** (cyclopropane label).
For the benzyl label M310I010 was found at amounts of 0.729 mg/kg (69.1% TRR) in urine and 0.022 mg/kg (38.0% TRR) in kidney. M310I011 accounted for 0.176 mg/kg (16.7% TRR) in urine and 0.010 mg/kg (16.6% TRR) in kidney. M310I010 was also detected in milk (0.003 mg/kg or 29.6% TRR). Both label-specific metabolites M310I010 and M310I011 were detected at low amounts in the liver acetonitrile extract as well as in the liver pronase solubilizate (together 5.3% and 4.6% TRR, respectively).
For the cyclopropane label M310I001, M310I003 and M310I004 accounted for 2.099 mg/kg (19.3% TRR), 1.974 mg/kg (18.1% TRR) and 4.584 mg/kg (42.1% TRR) in urine and for 0.033 mg/kg (9.6% TRR), 0.012 mg/kg (3.5% TRR) and 0.058 mg/kg (16.8% TRR) in kidney. Metabolite M310I001 was also detected at lower amounts in feces, liver, fat and muscle (all <4.3% TRR). M310I004 was also found in bile (0.226 mg/kg, 9.9% TRR) and liver at 0.012 mg/kg (2.5% TRR).

The metabolite **M310I021** was the most prominent component detected in bile of both labels, accounting for 0.156 mg/kg (25.7% TRR) for the benzyl label and 1.121 mg/kg (48.9% TRR) for the cyclopropane label. M310I021 was also detected in liver of both labels, where it was one of the most abundant components (4.7% and 7.4% TRR).

Additionally, the metabolites **M310I015** and **M310I017** were detected in feces of the cyclopropane label at minor concentrations (3.3% TRR and 4.1% TRR, respectively).

A number of additional HPLC peaks in the extracts was not identified, but characterized based on their chromatographic properties. For milk and the edible tissues of both labels the characterized components were always below 0.010 mg/kg or 10% of the TRR.

1. Metabolic pathway

The proposed metabolic pathway of BAS 310 I in goat is shown in Figure 6.2.3-1. Metabolism of ^{14}C-BAS 310 I in the lactating goat proceeds via hydroxylation and conjugation of the phenoxybenzyl and / or cyclopropyl moiety of the molecule (metabolites M310I015, M310I017 and M310I021). A further metabolic route is the cleavage of the ester bond and loss of the nitrile group leading to the label specific metabolites M310I001 and M310I011. Hydroxylation or conjugation of the latter cleavage products with glycine or glucuronic acid leads to the metabolites M310I003, M310I004 and M310I010.

2. Enantiomer ratio

In order to analyze whether one isomer of alpha-cypermethrin was preferably metabolized in goats, enantiomer-specific analysis of the parent compound BAS 310 I, isolated from selected matrices, was performed. For both labels, matrix-specific differences were observed for the isomer ratio. While in feces the ratio of both isomers of BAS 310 I was found to be approximately 1:1 for both labels, the relative amount of the (S)-cyano-(1R,3R) (isomer 1) was lower compared to the (R)-cyano-(1S,3S) (isomer 2) in the other investigated matrices (milk and renal fat in the case of the benzyl label, milk, composite fat and composite muscle in the case of the cyclopropane label). The relative amounts of isomer 1 : isomer 2 ranged from values of 16.0% : 84.0% to 22.2% : 77.8%.

3. Storage stability

Investigations of storage stability were performed in selected goat matrices at the beginning and at the end of the study. For this purpose, initial analyses of the extracts were carried out within six months after sampling. Re-analyses of stored extracts and re-extractions were performed, namely for milk (benzyl label, investigated due to a further metabolite in comparison to the cyclopropane label), liver and kidney (both labels, due to different metabolite patterns) and muscle (cyclopropane label, only investigated for this label).
For milk (benzyl label), liver, kidney (both labels) and composite muscle (cyclopropane label), the chromatograms obtained from stored extracts and re-extracted samples were in good accordance with the initial analysis. For liver of the cyclopropane label the chromatograms from stored extracts and re-extracted samples agreed likewise well with the peak pattern of the initial extraction with the exception of the metabolite M310I021, a glucuronic acid conjugate, which was less prominent in the re-extracted as well as re-analyzed sample.
Altogether, stability of residues was demonstrated in milk, liver and kidney of the benzyl label for a storage interval of at least 584 days in stored matrix and for at least 439 days in stored extracts. For liver, kidney and composite muscle of the cyclopropane label stability of residues was demonstrated for at least 368 days in stored matrix and for at least 287 days in stored extracts.

III. CONCLUSION

The metabolism of ^{14}C-BAS 310 I (benzyl and the cyclopropane labeled test substance) was investigated in lactating goats. The test substance was fed to the animals at a nominal dose level of 12 mg/kg feed for seven consecutive days. During the application period, aliquots of milk, urine and feces were taken for the determination of the radioactive residues. Tissues and organs (liver, kidney, muscle and fat samples) and bile were collected after animal sacrifice.
For the benzyl label the major route of excretion of radioactivity was via the feces, amounting to 59.9% of the total administered dose while, 13.1% of the total administered dose were excreted via urine. For the cyclopropane label 32.5% of the total administered dose were excreted via feces and 41.8% via urine.
In the pooled urine samples 1.055 mg/kg (24-144 h, benzyl label) and 10.903 mg/kg (24-156 h, cyclopropane label) were found. In the pooled feces samples radioactive residues amounted to 7.635 mg/kg (24-144 h, benzyl label) and 10.779 mg/kg (24-156 h, cyclopropane label).
The pooled milk samples represented low residue levels of 0.010 mg/kg (103-127 h, benzyl label), 0.053 mg/kg (55-96 h, cyclopropane label) and 0.044 mg/kg (103-127 h, cyclopropane label).The total radioactive residues (TRR) in organs for the benzyl and cyclopropane label amounted to 0.086 mg/kg and 0.489 mg/kg for liver, and 0.058 mg/kg and 0.345 mg/kg for kidney. Bile contained 0.606 mg/kg (benzyl label) and 2.290 mg/kg (cyclopropane label). For the benzyl label the TRR in edible tissues amounted to 0.024 mg/kg for omental fat, 0.031 mg/kg for renal fat, 0.011 mg/kg for subcutaneous fat and 0.004 mg/kg for loin and flank muscle. Considering the cyclopropane label, the TRR in edible tissues was 0.049 mg/kg for composite fat (goat 3), 0.141 mg/kg for composite fat (goat 4), and 0.029 mg/kg for composite muscle.

The extractability of the radioactive residues was high for both labels (≥89.9% TRR). Only for liver (both labels), muscle (benzyl label) and kidney (cyclopropane label) extractability was somewhat lower (between 61.1% and 85.4% TRR). Muscle extract of the benzyl label was not further investigated due to the low residue levels (0.004 mg/kg). The predominant part of the radioactive residues was extracted with acetonitrile (or a mixture of acetonitrile and isohexane) (>85% TRR), just from liver and kidney higher portions were extracted with water (between 18.4% and 36.3% TRR). The residual radioactive residues (RRR) after solvent extraction of liver and kidney were further solubilized with pronase, resulting in an additional release of 14.0-38.9% TRR.

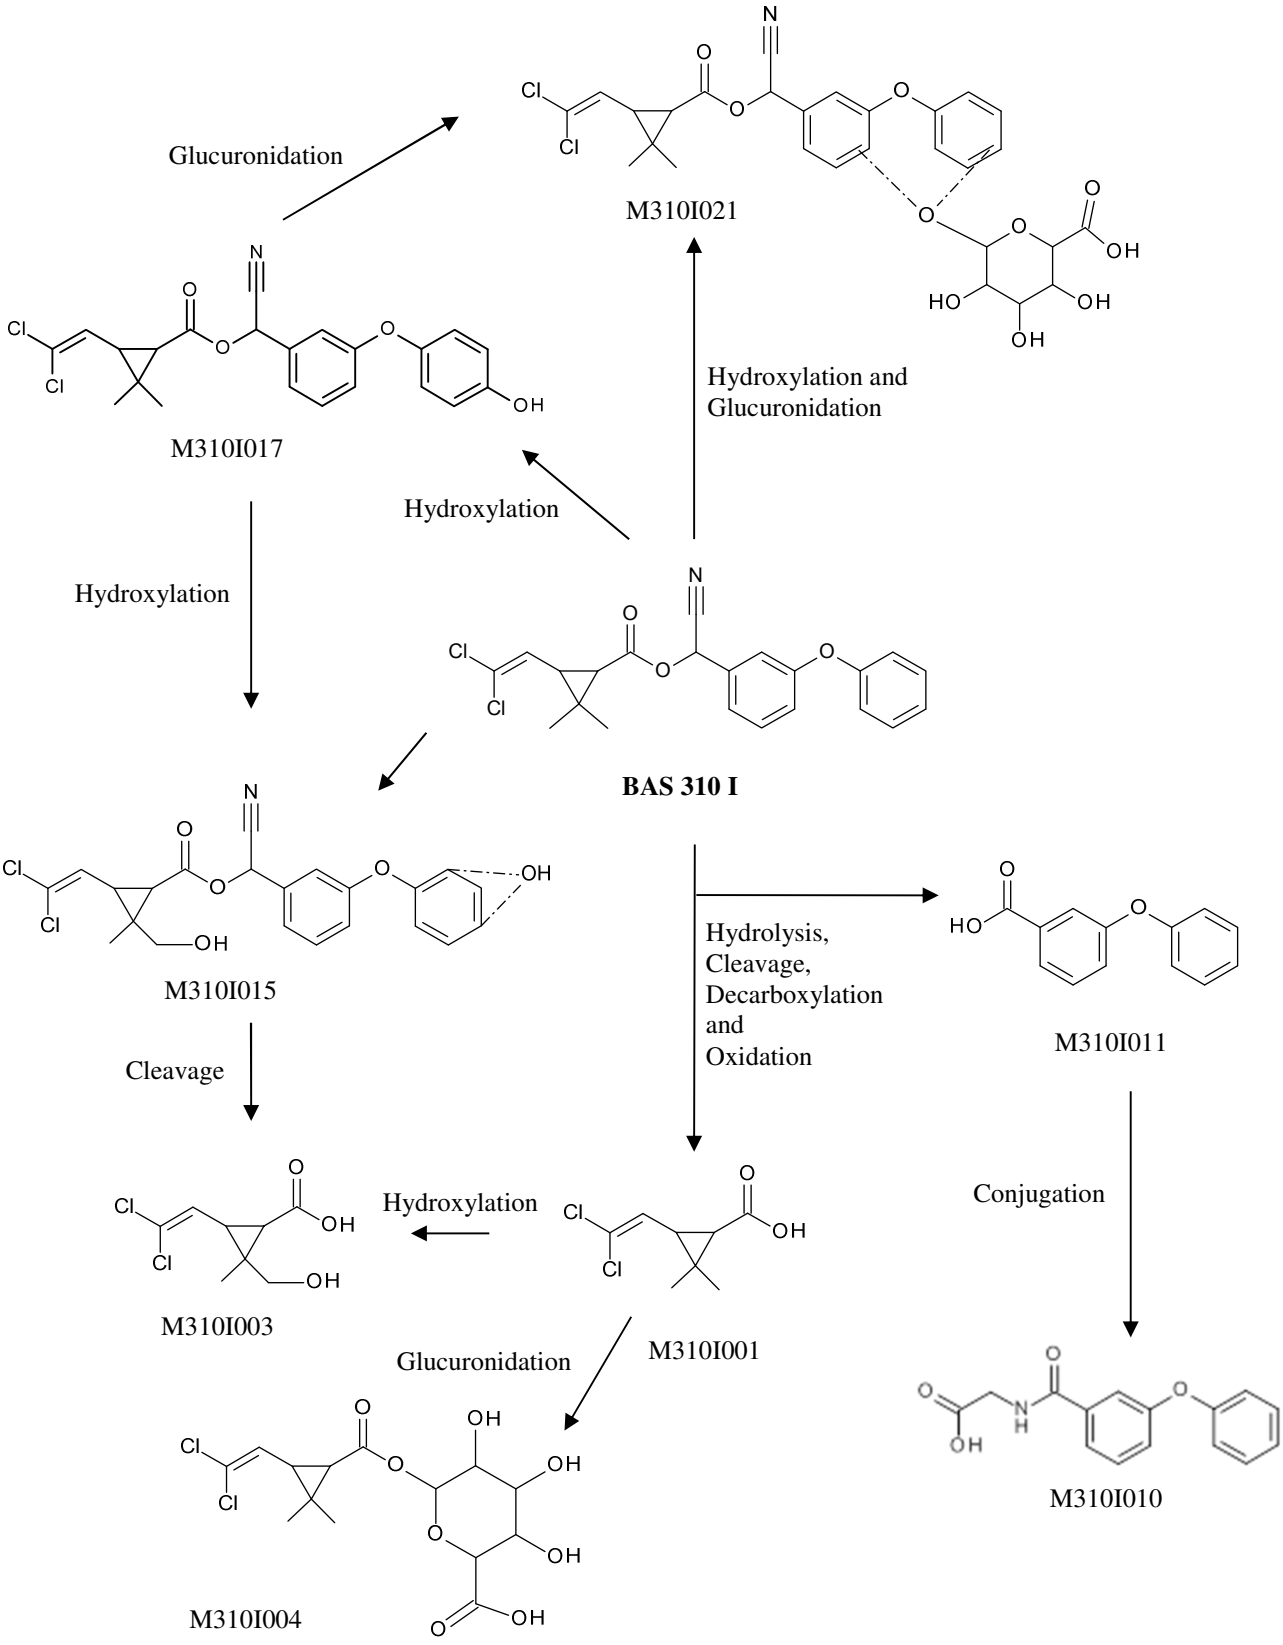
The unchanged parent compound was the main component in feces, milk, fat and muscle of both labels, representing 51.9-92.6% TRR.
High amounts of label-specific metabolites were detected in kidney and urine. For the cyclopropane label these were the metabolites M310I001 (9.6-19.3% TRR), M310I003 (3.5-18.1% TRR) and M310I004 (16.8-42.1% TRR) and for the benzyl label the metabolites M310I010 (38.0-69.1% TRR) and M310I011 (16.6-16.7% TRR).
The benzyl label specific metabolite M310I010 was also detected in milk (29.6% TRR) and liver (5.3% TRR) and label specific M310I011 at low amounts in liver (4.6% TRR).
For the cyclopropane label M310I001 was also detected in low amounts in fat and muscle (≤4.1% TRR) and M310I004 in liver and bile (2.5% and 9.9% TRR).
Further detected metabolites include M310I021 in bile (25.7-48.9% TRR) and liver (4.7-7.4% TRR) of both labels as well as M310I015 and M310I017, detected in feces of the cyclopropane label at minor concentrations (3.3% TRR and 4.1% TRR, respectively).

Several further components were characterized by their HPLC elution behavior and were below 10% TRR in all edible matrices.

Metabolism of ^{14}C-BAS 310 I in lactating goat proceeds via hydroxylation and conjugation of the phenoxybenzyl and cyclopropyl moieties of the molecule (metabolites M310I015, M310I017 and M310I021). A further metabolic route is the cleavage of the ester bond and loss of the nitrile group leading to the metabolites M310I001 and M310I011. Hydroxylation or conjugation of the latter compounds with glycine or glucuronic acid leads to the metabolites M310I003, M310I004 and M310I010. The main biotransformation reactions were also observed in rats and laying hens, so there is a consistent picture of the metabolism of ^{14}C-BAS 310 I in all animal species investigated.

In order to analyze if one enantiomer of alpha-cypermethrin was preferably metabolized in goats, enantiomer-specific analysis of the parent compound BAS 310 I, isolated from selected matrices, was performed. For feces of both labels analysis resulted in an enantiomer ratio of approximately 1:1, while the relative amount of one enantiomer was lower in the other investigated matrices (milk and renal fat in case of the benzyl label, milk, composite fat and composite muscle in case of the cyclopropane label) compared to the other enantiomer. The relative amount ranged from values from 16.0% to 22.3% TRR of the (S)-cyano-(1R,3R) enantiomer in comparison to relative amounts between 77.8% and 84.0% TRR of the (R) cyano-(1S,3S) enantiomer.

Figure 6.2.3-1: Proposed metabolic pathway of BAS 310 I in goat



CA 6.2.4 Pigs

No metabolism study was performed in pigs, since the metabolite patterns in rodents (rats) and ruminants (goats) did not differ significantly.

CA 6.2.5 Fish

According to Commission regulation 283/2013, metabolism studies in fish may be required where the plant protection product is used in crops whose parts or products, also after processing, are fed to fish and where residues in feed may occur from the intended applications.

The conditions under which such a study should be performed are further described in the Working document of the EU Commission SANCO/11187/2013, rev. 3 on the nature of pesticide residues in fish. The document specifies that the accumulation of compounds with low lipophilicity via the diet is known to be negligible and that fish metabolism studies are therefore required for active substances with a log P_{ow} equal or greater than 3 and an expected feed burden above 0.1 mg/kg DM.

In case of alpha-cypermethrin the log P_{ow} is 5.5 at 20°C without effect of pH (see Review Report, SANCO SANCO/4335/2000 final 13 February 2004). In this dossier, oilseed and cereals (barley and wheat) are submitted which are considered to serve as feed item for fish. Therefore, a metabolism study in fish was performed which is described below.

Guidelines:	SANCO/11187/2013 Rev. 3 (Working document)
GLP:	yes (certified by Department of Health of the Government of the United Kingdom, United Kingdom)

Executive summary

The purpose of this study was to investigate the metabolism of alphacypermethrin (BAS 310 I) in rainbow trout following 14 consecutive daily doses of BAS 310 I fortified feed, at a target dose of 10 mg/kg.
Alphacypermethrin (BAS 310 I) metabolism in trout was investigated with [Benzyl-U-^{14}C]-BAS 310 I (radiochemical purity 99.5%) and [Cyclopropane-^{14}C]-BAS 310 I (radiochemical purity 96.9%). The in-life and analytical phases of this study were performed at Charles River Preclinical Services, Tranent, Edinburgh, EH33 2NE, UK.
The benzyl-labelled form of BAS 310 I was radiodiluted with [Phenoxy-^{13}C]-BAS 310 I in a 4:1 ratio, and the cyclopropane label was radiodiluted with non radiolabelled BAS 310 I in the same ratio. The final specific activity of the radiolabelled BAS 310 I was 3.8 MBq/mg.

Thirteen fish were treated per radiolabelled experiment (26 in total) with a nominal rate of 10 mg of test item per kg of feed. Fish were fed at a rate of ca. 2% tank biomass per day, with the rate increased on day 7 of the administration phase to take into account the increase in tissue mass.
Three whole fish were taken for each experiment 10 and 12 days following the first dose and fillets removed for total residue analysis. Daily samples included faeces which was collected prior to and following administration, and samples of tank water. On day 14, approximately 6 h post final dose all remaining fish were humanely killed and tissues (liver, fillet, skin, muscle, pyloric caeca, cleaned GI tract and remaining carcass) and the hind gut content removed post mortem.
Sub-samples of the fish samples were taken for initial TRR determination employing sample oxidation analysis or following extraction, by summing radioactivity in the extracts and unextracted residues. Fish tissue was extracted using acetonitrile and Milli-Q water. Further extractions were carried out as necessary, with protease enzyme (37ºC; 72h).

Fillet

Fish fillets were sampled from whole fish taken 10 and 12 days into treatment with BAS 310 I. The radioactive residues at day 10 were 0.070 mg/kg and 0.083 mg/kg, at day 12 residues were 0.090 and 0.053 mg/kg for fish treated with [Benzyl-U-^{14}C]-BAS 310 and [Cyclopropane-^{14}C]-BAS 310 I labels, respectively. TRR data for the fillets at day 14 were calculated from the skin and muscle tissues, in natural proportions, which were analysed separately. TRR was calculated as 0.105 and 0.083 mg/kg for [Benzyl-U-^{14}C]-BAS 310 and [Cyclopropane-^{14}C]-BAS 310 I labels, respectively. No further analysis was carried out on the 10 and 12 day fillet fractions.

Muscle, Liver and Skin

The TRR of fish matrices taken at the final day of treatment (Day 14) with [Benzyl-U-^{14}C]-BAS 310 I were 0.094 mg/kg for muscle, 0.184 mg/kg for skin and 0.241 mg/kg for liver. Corresponding values for fish treated with [Cyclopropane-^{14}C]-BAS 310 I were 0.076 mg/kg for muscle, 0.127 mg/kg for skin and 0.299 mg/kg for liver. The majority of the residue in muscle and skin were extractable (≥90.2% TRR), further extraction of the liver with protease resulted in extractability of (≥59.1% TRR).
Parent compound BAS 310 I was detected in all fish matrices analysed at 75.9 % TRR (0.071 mg/kg) in muscle, 70.6 % TRR (0.130 mg/kg) in skin and 7.1% TRR (0.017 mg/kg) in liver for the [Benzyl-U-^{14}C]-BAS 310 I label. Corresponding values for fish treated with the [Cyclopropane-^{14}C]-BAS 310 I were 78.0 % TRR (0.060 mg/kg) in muscle, 71.7 % TRR (0.091 mg/kg) in skin and 3.8% TRR (0.011 mg/kg) in liver. Hydroxylated BAS 310 I contributed to ≤9.6% TRR (≤0.009 mg/kg) in muscle, ≤9.9% TRR (≤0.018 mg/kg) in skin and ≤5.6% TRR, (0.013 mg/kg) in liver. Multiple isomeric glucuronides of BAS 310 I were also detected as the principal residue in liver samples at ≤25.1% TRR (0.061 mg/kg). Unidentified extractable metabolites individually accounted for ≤0.006 mg/kg, and unextracted residues were ≤0.008 mg /kg in the muscle and skin and ≤0.099 mg/kg in the liver.

B. EXPERIMENTAL

The study was conducted during the period 13 February 2014 to 06 October 2014 at Charles River, Tranent, EH33 2NE, Scotland.

1. In-Life Phase

The in-life phase was conducted in round fibreglass tanks in a temperature controlled laboratory at Charles River, Tranent, EH33 2NE, Scotland. Twenty-six rainbow trout (Oncorhynchus mykiss) *ca*. 2 years old were obtained from Belhaven Trout Company Ltd (Dunbar, Scotland, UK) and received on 02 May 2014. Fish were in good health and free from any apparent malformation. The fish were maintained at the test facility for 14 days prior to test item administration. The weight of each fish was *ca*. 250-300 g and the weight variation did not exceed +/- 25% of the average weight.

The study fish were housed in two separate tanks *ca*. 1400 L capacity, (1.5 m diameter x 0.8 m deep) covered with perspex lids with ventilation holes to prevent fish escaping, dust contamination and evaporation loss. The tanks were filled with reconstituted freshwater (RFW) to *ca*. 800 L and the volume maintained throughout the study. Holding and test tanks were maintained within a laboratory at a temperature of 13-17°C. A light cycle of 16 h light and 8 h dark was in operation throughout the test, illumination being provided by fluorescent tubes. Tanks were maintained under continuous flow conditions (*ca*. 2.45 L/ min per tank) and aerated to ensure that the dissolved oxygen concentration was at least 60% of air saturation, and filtration systems were employed to remove faeces during the testing period.

Before the dosing period fish were fed daily with standard fish feed (E Fico Alpha 717, 4.5mm, Biomar Limited, Grangemouth, UK). Fish were not fed in the 24 hrs prior to the initiation of this test. At commencement of the test a sample of feed was fortified with BAS 310 I and was used throughout the test period. Feed was offered at a rate of 2.0% estimated tank biomass per day, for fourteen consecutive days. Feeding was observed and any excess food was removed by siphoning within 10 mins of addition to the tank in order to prevent contamination of the water.

2. Sampling

Three fish were sampled from each radiolabelled experiment on day 10 and day 12 of the treatment regime. On day 14 of the administration phase all remaining fish were sacrificed and dissected into samples of muscle (without skin), skin (from muscle sample), liver, fillet, cleaned GI tract, hind gut contents (combined with faeces), pyloric caeca and residual carcass. Throughout the study all fish sampled were sacrificed with a blow to the back of the head followed by destruction of the brain. Daily samples of uneaten feed, faces and water were taken throughout the course of study.

3. Analytical procedures

Fish tissues were pulverised in dry ice which was allowed to sublime prior to determination of TRR by combustion analysis followed by liquid scintillation counting (LSC). Muscle, liver and skin samples from the 14 day sampling were extracted three times in acetonitrile followed by ultrapure water twice. Where necessary, further extractions were conducted with protease enzyme (37°C, for a total of 72 h). The unextracted radioactivity in the post-extraction solids was determined by combustion analysis followed by LSC. Extractability was determined for each sample by summing radioactivity in the extracts and unextracted residues.

Extracts were analysed using a reversed phase HPLC (Synergi Fusion – RP) column eluted with a gradient of water and acetonitrile containing 0.1% formic acid. The effluent was passed through a UV detector (230 nm) to detect reference standards. A second HPLC method and LC-MS was conducted to confirm the presence of metabolites.

4. Lipid Extraction and Determination

Lipid content of the tissues and feed were obtained by extracting in methanol and chloroform. The chloroform layer of each extract was dried by passing through anhydrous sodium sulphate (ca. 1-2 g) and the lipid content weighed after removing the solvent under a stream of nitrogen gas.

II. RESULTS AND DISCUSSSION

A. TOTAL RADIOACTIVE RESIDUES (TRRS)

Rainbow trout (*Oncorhynchus mykiss*) were administered fish feed fortified with [^{14}C]-BAS 310 I at a target dose of 10 mg/kg over a period of 14 days. Whole fish samples were taken at 10, 12 and 14 days. On day 14 fish were dissected into liver, residual carcass, faeces, pyloric caeca, hind gut content, cleaned GI tract and edible tissues (skin and muscle). Fish tissues were pulverised and extracted where required. The total radioactive residue (TRR) was determined as the sum of radioactivity in each extract and the unextracted residue.

1. Fillet

TRR in fillet treated were ≤0.105 mg/kg and ≤0.083 mg/kg for the [Benzyl-U-^{14}C]-BAS 310 I and [Cyclopropane-^{14}C]-BAS 310 I respectively. All values are presented below:

Table 6.2.5-1: Total Radioactive Residues of [^{14}C]-BAS 310 I in Trout Fillet

	Day 10 mg/kg	**Day 12 mg/kg**
Bz -^{14}C	0.070	0.090
Cy-^{14}C	0.083	0.053

Day 14	**Muscle (mg/kg)**	**Skin (mg/kg)**	**Total in natural proportions (mg/kg)**
Bz -^{14}C	0.094	0.184	0.105
Cy-^{14}C	0.076	0.127	0.083

2. Muscle, Liver and Skin

TRR data for muscle, liver and skin is provided below. Liver residues were the highest of all tissues extracted, 0.241 mg/kg and 0.299 mg/kg for the benzyl and cyclopropane labels respectively. The lowest residues were detected in the muscle, 0.094 mg/kg and 0.076mg/kg for the benzyl and cyclopropane labels respectively.

Table 6.2.5-2: Total Radioactive Residues of [^{14}C]-BAS 310 I in Muscle, Liver and Skin (after 14 Daily Doses of [^{14}C] BAS 310 I at 10 mg/kg Feed Nominal)

Fish Matrix	Interval	[Benzyl-U-^{14}C]-BAS 310 I (mg/kg)[1)]	[Cyclopropane-^{14}C]-BAS 310 I (mg/kg) [1)]
Muscle	14	0.094	0.076
Liver		0.241	0.299
Skin		0.184	0.127

1)TRR values were determined as the sum of the extracted + unextracted radioactivity.

3. Lipid Content

The measured lipid content of the muscle, skin, liver and feed are presented in Table 6.2.5-3. Muscle tissue contained 4.5 - 4.6 % lipid.

Table 6.2.5-3: Lipid Content of Tissues (after 14 Daily Doses of [^{14}C] BAS 310 I at 10 mg/kg Feed Nominal)

Tissue	[Benzyl-^{14}C] label % Lipid content	[Cyclopropane-^{14}C] label % Lipid content
Muscle	4.5	4.6
Skin	2.9	1.9
Liver	1.3	1.9
Feed	16.6	

B. EXTRACTION AND CHARACTERISATION OF RESIDUES

The extractability of the ^{14}C residues in fish samples was determined using acetonitrile followed by water. Where necessary, further extractions were conducted with protease enzyme (37°C, 72 h). The unextracted radioactivity in the post-extraction solids was determined by combustion analysis followed by LSC.

1. Extraction and characterisation of residues in muscle, liver and skin
   The total radioactive residues in muscle, liver and skin ranged from 0.076 to 0.299 mg/kg with BAS 310 I present in all samples (≤0.130 mg/kg).

   Muscle

   The parent BAS 310 I was the principal residue detected in both radiolabelled experiments at 75.9 and 78.0% TRR for the benzyl and cyclopropane labels, respectively. Hydroxylated BAS 310 I accountined for 9.6% and 7.9 %TRR (0.009 mg/kg and 0.006 mg/kg) for the benzyl and cyclopropane labels, respectively. All remaining residues were ≤3.0 %TRR (≤0.002 mg/kg).

   Skin

   The parent BAS 310 I was the principal residue detected in both radiolabelled experiments at 70.1 and 71.7 % TRR (0.130 and 0.091 mg/kg) for the benzyl and cyclopropane labels, respectively. Hydroxylated BAS 310 I accounted for 9.9 and 9.7 %TRR (0.018 mg/kg and 0.012 mg/kg) for the benzyl and cyclopropane labels, respectively. All remaining residues were ≤2.7 %TRR (≤0.003 mg/kg).

   Liver

   The parent BAS 310 I was detected in both radiolabelled experiments at 7.1% and 3.8 % TRR (0.017 and 0.011 mg/kg) for the benzyl and cyclopropane labels, respectively. The principal residue was multiple isomeric glucuronides of BAS 310 I detected at 25.1% and 19.7 % TRR (0.061 and 0.059 mg/kg) for the benzyl and cyclopropane labels, respectively. hydroxylated BAS 310 I accounted for 5.6 %and 4.3 %TRR (0.013 mg/kg and 0.013 mg/kg) for the benzyl and cyclopropane labels, respectively. All remaining residues were individually ≤4.0 %TRR (≤0.012 mg/kg) and were not possible to identify due to the low response in each case.

2. Storage stability of residues

   Samples were stored in a freezer set to maintain *ca*. -20°C and storage intervals recorded. All extraction, fractionation and HPLC analysis was completed within 6 months of sacrifice therefore storage stability was not performed.

3. Identification of BAS 310 I and metabolites

   The identities of the principal fish residue components were investigated by comparison of the extractable residues with different reference standards of BAS 310 I and its authenticated analytical reference standards. BAS 310 I was observed as the primary residue in skin and muscle of the fish (≤0.130 mg/kg) and this identification was confirmed by, MRM analysis. The residues corresponding to hydroxylated BAS 310 I and isomeric glucuronides of BAS 310 I were also confirmed by LC-MS.

4. Proposed metabolic pathway

BAS 310 I was observed as the primary residue in the skin and muscle of the fish with lower levels of hydroxylated BAS 310 I. BAS 310 I was metabolised more extensively in the liver. Glucuronic acid conjugatation of the hydroxylated BAS 310 I was the primary residue in liver together with hydroxylated BAS 310 I and unchanged BAS 310 I.

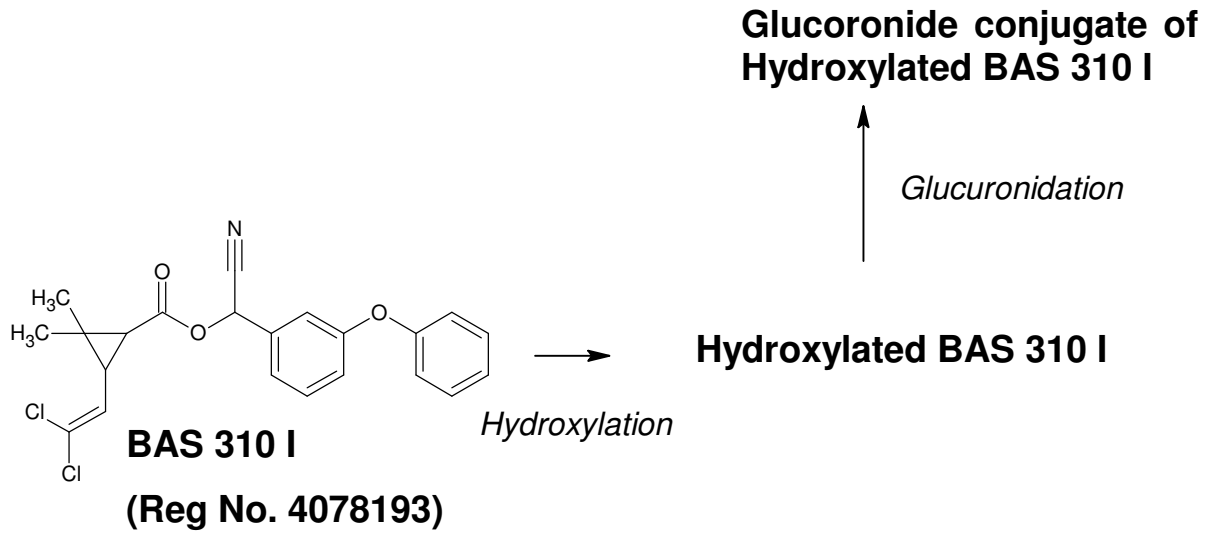
III. CONCLUSION

Radioactivity in fillet rose steadily in the benzyl label to a maximum of 0.105 mg/kg at day 14, the cyclopropane labelled fillet was 0.083 mg/kg at both day 10 and day 14.
The solvent extractability of muscle and skin was high (≥90.2% TRR). Further extraction with protease enzyme was carried out on liver (both labels) and skin benzyl label to achieve extractability of ≥59.1%.
BAS 310 I was observed as the primary residue in the skin and muscle of the fish (70.1 to 78.0 %TRR, 0.060 to 0.130 mg/kg) with lower levels of hydroxylated BAS 310 I (7.9 to 9.9 %TRR, 0.006 to 0.018 mg/kg). BAS 310 I was metabolised more extensively in the. Glucuronic acid conjugatation of the hydroxylated BAS 310 I was the primary residue (19.7 to 25.1 %TRR, 0.059 to 0.061 mg/kg) together with hydroxylated BAS 310 I and unchanged BAS 310 I.

Figure 6.2.5-1: Proposed metabolic pathway for BAS 310 I in Rainbow Trout



Overall Summary Livestock Metabolism

The present Annex I renewal dossier provides new metabolism studies in goat, hen, fish and rat. The new studies mainly confirm the findings and degradation reactions known so far and complement additional details due to more sensitive technology.

Combining the findings of the older metabolism studies and the new ones, a system of degradation reactions results which can not only explain most of the facts gathered so far but also lead to a more complete picture.

The general metabolic pathway in rats and ruminants was found to be comparable. Hydrolysis of the ester bond of BAS 310 I results in a cyclopropane and a phenoxybenzyl moiety of the molecule. The cyclopropane moiety corresponds to metabolite M310I001 (DCVA) which in **hen**, **goat** and **rat** is hydroxylated to give M310I003 and subsequently, via glucuronidation, is transformed into M310I002 (**rat**). Glucuronidation of M310I001 to yield M310I004 was shown in **goat** and **rat**.

Cleavage of the nitrile group of the phenoxybenzyl moiety and oxidation yields M310I011 (3-phenoxybenzoic acid), which was identified in the **rat** and **goat** metabolism studies. M310I011 can be cleaved to give M310I019 (3-Hydroxybenzoic acid; found in **hen**) or via hydroxylation and conjugation form M310I013 and M310I014 (**rat**). Conjugation of M310I011 with glycine leads to M310I010 (N-(3-phenoxybenzoyl)glycine, found in **goat** and **rat**), which can be hydroxylated to give M310I012 (rat).

A further metabolic route are hydroxylation and conjugation of the phenoxybenzyl and / or cyclopropyl moiety of the alpha-cypermethrin molecule without prior ester cleavage leading to metabolites M310I015 (**goat** and **rat**), M310I017 (4'hydroxy-alpha-cypermethrin; **goat** and **rat**), and M310I021 (Glucuronide conjugate of alpha-cypermethrin, **goat** and **fish**). Hydroxylation and glucuronidation of uncleaved alpha-cypermethrin to give the glucuronide conjugate M310I021 were the only metabolic reactions demonstrated in fish.

A complete picture including rat, goat, hen and fish results is shown in Figure 6.2.5-2.

CA 6.3 Magnitude of residues trials in plants

Alpha-cypermethrin is registered in multiple crops belonging to different EU crop groups. Within this dossier residue data are only provided for the representative uses supporting the renewal of approval. The ME formulation BAS 310 55 I has been selected as representative formulations.

Consequently, in this dossier section the relevant data for the following crops are summarized:

- Cucumber (for extrapolation to courgette)
  Leafy brassica
  Lettuce
  Oilseed rape
- Cereals (barley and wheat))

The studies provided below for cucumber, leafy brassica, lettuce, oilseed rape and cereals have not been evaluated within the MRL re-evaluation process according to Reg. 396/2005, Art. 12. Consequently they are not considered as peer-reviewed.

CA 6.3.1 Cucumber

Residue trials under glasshouse conditions were performed in the years 2004/2005. According to SANCO 7525/VI/95 - rev.9, March 2011, extrapolation is possible from cucumber to courgettes. Therefore, residue trials in cucumber that support the GAP for courgettes are presented in the following.

Table 6.3.1-1: cGAP for the use of BAS 310 I in/on cucumber

Crop	Maximum applied dose	Water volume	PHI	Application method	Application timing
Cucumber / Courgette, indoor (North, Central)	1 x 0.030 kg BAS 310 I/ha	200–1500	3	Overall spray	BBCH 10-89
Cucumber / Courgette, indoor (South)	2 x 0.015 kg BAS 310 I/ha	200–1500	3	Overall spray	BBCH 10-89
	1 x 0.030 kg BAS 310 I/ha	200–1500	3	Overall spray	BBCH 10-89

PHI = pre-harvest interval

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31041I
Description: BAS 310 41 I (SC)
Lot/Batch #: 4000: 100 g/L
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01 and 1.0 mg/kg

2. Test Commodity:
Crop: Cucumber
Type: Cucurbits edible peel
Variety: Euphoria, Sheila, Naomi, Suxo, Solverde, Rawa, Palmera, Hiyield
Botanical name: *Cucumis sativus*
Crop parts(s) or processed commodity: fruit
Sample size: 0 DALA (days after last application): 12 fruit (min. 0.5 kg)
3±1 DALA: 12 fruit (min. 1.0 kg)
7±1 and 14±1 DALA: 12 fruit (min. 2.0 kg)

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2004 growing season, eight trials were conducted in cucumbers grown in glasshouses. A soluble concentrate formulation of alpha-cypermethrin (100 g a.s./L; BAS 310 41 I) was foliar applied to cucumbers on two different plots. In one variant, one application was made at a target rate of 0.015 kg alpha-cypermethrin/ha 7±1 days before harvest. This was compared to another variant in which two applications were made at the same target application rate, 14±1 and 7±1 days before harvest. The target water volume was 400 L/ha.

Cucumber fruit specimens were collected directly after the last application as well as 2-4, 7-8 and 13-14 days thereafter. There were some slight deviations from the targeted sampling parameters ("quantity"), none of which influenced the results of the study, which occurred at trial GRE/12/04. At 3 DALA, only eight cucumbers from plot 2 and six cucumbers from plot 3 were harvested, and at 14 DALA, only six cucumbers from plot 3 were collected.
Samples were stored frozen at or below -18°C including during transportation, until analysis, except for the samples denoted by an asterisk ("*") in Table 6.3.1-6 below (several samples from trials AGR/10/04 and ALB/07/04, and all samples from trial ITA/09/04). These samples were shipped frozen (packed in dry ice) by airfreight from BASF Aktiengesellschaft (Limburgerhof, Germany) on 29 November 2004 and were received unfrozen at BASF Agro Research (Research Triangle Park, North Carolina, U.S.A) on 08 December 2004. The samples defrosted for a brief period on account of delays incurred while in customs. The samples were cold and in good condition for residue analysis. The maximum frozen storage interval between sampling and extraction was 252 days.

Table 6.3.1-3: Target application rates and timings for cucumber

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2004	8	1	G	BAS 310 41 I (SC)	alpha-cypermethrin	0.015	400	7 ±1 days before harvest
		2	G	BAS 310 41 I (SC)	alpha-cypermethrin	0.015	400	1st appl. 14 ±1, 2nd appl. 7 ±1 days before harvest

2. Description of analytical procedures

The specimens were analysed by means of HPLC-MS/MS for total cypermethrin residues with BASF method No. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.
Principle of method: Residues of cypermethrin (alphacypermethrin or cypermethrin) are extracted with a mixture of methanol/water/2N hydrochloric acid (70:25:5). An aliquot of the extract is centrifuged, and cleaned by liquid/liquid partition against cyclohexane. The final determination of total cypermethrin residues is performed by HPLC-MS/MS.

Table 6.3.1-4: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in cucumber

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
fruit	0.01	4	80.7	14.3	17.7
	1.0	4	101.9	17.7	17.4
	Overall	8	91.3	18.7	20.5

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.1-5, detailed residue levels are shown in Table 6.3.1-6.
Immediately after one application of 0.015 kg alpha-cypermethrin/ha in the glasshouse, residues in cucumber fruit ranged from below the LOQ (<0.01 mg/kg) to 0.026 mg/kg. Residues were detected (0.023 and 0.026 mg/kg) at only two of the eight trial locations. Total cypermethrin residues were <0.01 mg/kg in all samples collected thereafter (2-14 days after application).
Immediately after the last of two applications at a rate of 0.015 kg alpha-cypermethrin/ha, total residues of cypermethrin in cucumber ranged from below the LOQ (<0.01 mg/kg) to 0.030 mg/kg. Residues decreased to <0.01-0.012 mg/kg at 2-4 days after the last application, and were <0.01 mg/kg in all samples collected thereafter (7-14 days after the last application).
No residues above the LOQ were found in any of the untreated samples.

Table 6.3.1-5: Summary of residues of BAS 310 I in cucumber after application of BAS 310 41 I

Region	Year	Application	DALA[1]	Growth stage[2] BBCH	Residues Found (mg/kg)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31040I
Description: BAS 310 40 I (EC)
Lot/Batch #: 1171: 100.0 g/L
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01, 0.1 and 1.0 mg/kg

2. Test Commodity:
Crop: Cucumber
Type: Cucurbits edible peel
Variety: Defens, Avonis, Loretta, Naomi, Columbia, Jumbo, Suso, Luberon
Botanical name: *Cucumis sativus*
Crop parts(s) or processed commodity: fruit
Sample size: 12 items (2 kg)

B. STUDY DESIGN AND METHODS

1. Test procedure

During the growing season of 2005, eight greenhouse trials with cucumber were conducted in Southern France, Germany, Belgium, Denmark, Italy, Spain and Greece in order to determine the magnitude of the residues of alpha-cypermethrin.
Each greenhouse trial consisted of two plots, one untreated control plot and one plot treated once with 0.4 L/ha of BAS 310 40 I (100.0 g/L of alpha-cypermethrin, EC formulation) corresponding to 40 g of active substance per hectare. The application took place at 7 days before harvest with an application rate of 400 L/ha of spray.

Samples of cucumber fruit were collected 0, 3, 7 and 14-15 days after application.
The maximum storage interval was 492 days.

Table 6.3.1-7: Target application rates and timings for cucumber

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2005	8	1	G	BAS 310 40 I (EC)	alpha-cypermethrin	0.040	400	7 ±1 days before harvest

2. Description of analytical procedures

The specimens were analysed by means HPLC-MS/MS for total cypermethrin residues with BASF method No. 567/0.
Principle of method: Residues of cypermethrin (alpha-cypermethrin or cypermethrin) are extracted with a mixture of methanol/water/2N hydrochloric acid (70:25:5). After centrifugation, an aliquot of the extract is cleaned by liquid/liquid partition against cyclohexane. The residues are further purified (if needed) using a silica gel solid phase extraction (SPE) column. The final determination of total cypermethrin residues is performed by HPLC-MS/MS, monitoring the ion transition from m/z 433.2 / 191.1 (the ammonium adduct of cypermethrin). The limit of quantitation (LOQ) of the method for alpha-cypermethrin is 0.01 mg/kg.

Table 6.3.1-8: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in cucumber

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
fruit	0.01	4	79.3	9.0	11.4
	0.1	2	85.8	-	-
	1.0	1	102.0		
	Overall	7	84.4	11.9	14.1

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.1-9, detailed residue levels are shown in Table 6.3.1-10.
Initial residues between <0.01 mg/kg and 0.087 mg/kg were found in cucumber fruit immediately after application of 40 g alpha-cypermethrin/ha in the greenhouse. Residues declined to <0.01-0.037 mg/kg after 3 days and further to <0.01-0.014 mg/kg at 7 and <0.01-0.011 at 14-15 days after application, respectively.
No residues of alpha-cypermethrin above the LOQ were analysed in any of the untreated specimens.

Study on the residue behaviour of Alpha-Cypermethrin in curly kale after treatment with BAS 310 40 I under field conditions in Northern and Southern Europe during 2005
2006/1026862
Guidelines: none
GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31040I
Description: BAS 310 40 I (EC)
Lot/Batch #: 1171, Alpha-Cypermethrin: 100 g/L
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01, 0.5 and 1.0 mg/kg

2. Test Commodity:
Crop: Curly kale
Type: Leafy brassica
Variety: Winterbox, Winneton, Black Toscano, Vates
Botanical name: *Brassica oleracea*
Crop parts(s) or processed commodity: Foliage
Sample size: 0 DALA (days after last application): 12 units (min. 1.0 kg)
3±1 DALA: 12 units (min. 1.0 kg)
7±1 DALA: 12 units (min. 2.0 kg)
14±1 DALA: 12 units (min. 2.0 kg)

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2005 and 2006 growing season, four field trials were conducted in different representative curly kale growing areas in the UK, Germany, Italy and Greece to determine the residue level of alpha-cypermethrin in or on Raw Agricultural Commodities (RAC).
At Trials AF/8815/BA/1 and 5 conducted in Northern Europe, BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g a.s./L), was foliar applied either once at 7 days before expected harvest (plot 2) or twice at 14 and 7 days before expected harvest (plot 3) at a rate of 0.125 L (equivalent to 0.0125 kg alpha-cypermethrin/ha) of formulated product /ha to curly kale. The nominal spray volume used was 400 L/ha.
At Trials AF/8815/BA/3 and 4 conducted in Southern Europe, BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g a.s./L), was foliar applied only once at 7 days before expected harvest (plot 2) at a rate of 0.25 L(equivalent to 0.025 kg alpha-cypermethrin/ha) of formulated product /ha to curly kale. The nominal spray volume used was 400 L/ha.
Specimens of kale leaves were collected at the day of the last application (0 DALA) from each plot as well as 3, 7 and 14 days thereafter.

Samples were stored frozen for a maximum of 213 days until analysis.

Table 6.3.2-4: Target application rates and timings for curly kale

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing

2. Description of analytical procedures

Specimens were analysed using BASF analytical method no. 567/0, which quantifies the residues of total cypermethrin by means of HPLC-MS/MS.
Principle of method:
Residues of cypermethrin (alpha-cypermethrin or cypermethrin) are extracted with a mixture of methanol/water/2N hydrochloric acid (70:25:5). After centrifugation, an aliquot of the extract is cleaned by liquid/liquid partition against cyclohexane. The residues are further purified (if needed) using a silica gel solid phase extraction (SPE) column. The final determination of total cypermethrin residues is performed by HPLC-MS/MS, monitoring the ion transition from m/z 433.2 / 191.1 (the ammonium adduct of cypermethrin).
The limit of quantitation (LOQ) of the method for alpha-cypermethrin is 0.01 mg/kg.

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Foliage	0.01	5	85.0	16.8	19.8
	0.5	2	91.5	-	-
	1.0	3	82.5	11.7	14.1
	Overall	10	85.6	12.9	15.1

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.2-6, detailed residue levels are shown in Table 6.3.2-7 and Table 6.3.2-8.
After a single broadcast foliar application of alpha-cypermethrin targeting 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in curly kale foliage ranged between 0.154 mg/kg and 0.159 mg/kg. Residues declined to levels between 0.203-0.227 mg/kg, 0.171-0.237 mg/kg and 0.083-0.116 mg/kg at 3, 7 and 14 days after application.

After two broadcast foliar applications of alpha-cypermethrin targeting at 0.0125 kg a.s./ha and application, initial residues were 0.241 mg/kg in kale foliage collected immediately after the last application. Residues declined to levels between 0.170-0.348 mg/kg, 0.084-0.383 mg/kg and 0.152-0.245 mg/kg at 3, 7 and 14 days after application.

After a single broadcast foliar application of alpha-cypermethrin targeting 0.025 kg a.s./ha, initial residues of alpha-cypermethrin in leafy cabbage ranged between 0.349 mg/kg and 0.517 mg/kg. Residues declined to levels between 0.278-0.436 mg/kg, 0.257-0.263 mg/kg and 0.137-0.243 mg/kg at 3, 7 and 14 days after application

In the control specimens, no residues of total cypermethrin above the limit of quantitation were found, with the following exception: At the trial located in the United Kingdom (AF188151BA/5) apparent residues of cypermethrin were approximately at the limit of quantitation (0.01 mg/kg) in the control material collected at 0 and 3 DALA, but were <0.01 mg/kg in untreated controls collected at 7 and 14 DALA. These residues were relatively low compared with the residues in the associated treated specimens. The source of the contamination could not be determined.

Table 6.3.2-6: Summary of residues of BAS 310 I in leafy cabbage after application of BAS 310 40 I

Region	Year	Application	DALA[1]	Growth stage[2] BBCH	Residues Found (mg/kg)	
					Matrix	alpha-cypermethrin (BAS 310 I)
N-EU	2005-2006	BAS 310 40 I (EC) 1 x 0.125 kg a.s./ha	0	48-49	Foliage	0.154-0.159

			14	49	Foliage	0.137-0.243

1 Days after last application
2 Growth stage at respective sampling

III. CONCLUSION

Immediately after the last of two treatments at a target rate of 0.0125 kg alpha-cypermethrin/ha, residues in leafy cabbage foliage were 0.241 mg/kg and ranged between 0.170-0.348 mg/kg and 0.084-0.383 mg/kg after 3 and 7 days, respectively.
Immediately after a single application of alpha-cypermethrin targeting 0.025 kg a.s./ha, initial residues of alpha-cypermethrin in leafy cabbage foliage ranged between 0.349 mg/kg and 0.517 mg/kg. Residues declined to levels between 0.278-0.436 mg/kg and 0.257-0.263 mg/kg at 3 and 7 days after application, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31040I

Description:	BAS 310 40 I (EC)
Lot/Batch #:	1171, Alpha-Cypermethrin: 100 g/L
Purity:	not reported
CAS#:	67375-30-8
Development code:	not reported
Spiking levels:	0.01, 0.10 and 1.0 mg/kg

2. Test Commodity:

Crop:	Leafy cabbage
Type:	Leafy brassica
Variety:	Reflex, Winnetou, Castelard, Manoko F-1
Botanical name:	*Brassica oleracea*
Crop parts(s) or processed commodity:	RAC leaves
Sample size:	min 2 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2006 growing season, four field trials were performed in leafy cabbage in France (Northern and Southern European region), Spain and The Netherlands.
In two trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to leafy cabbage plants either once or twice to separate plots at a target rate of 0.0125 kg alpha-cypermethrin/ha in a spray volume of 400 L/ha.

In two trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to leafy cabbage plants once at a target rate of 0.025 kg alpha-cypermethrin/ha in a spray volume of 400 L/ha.

Specimens of cabbage leaves were collected immediately after the last application from each plot, as well as 3-4, 6-8 and 14-15 days thereafter.

Samples were stored frozen a for a maximum of 136 days until analysis.

Table 6.3.2-9: Target application rates and timings for leafy cabbage

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2006	2	1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	400	7 ±1 days before harvest
		2	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	400	1st appl. 7 ±1, 2nd appl. 14 ±1 days before harvest
	2	1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.025	400	7 ±1 days before harvest

2. Description of analytical procedures

Specimens were analysed using BASF analytical method no. 567/0, which has a limit of quantitation of 0.01 mg/kg in all sample materials.
Residues of alpha-cypermethrin were extracted from leafy cabbage (leaves) using methanol/water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane/water. The cyclohexane phase was evaporated and the residue was dissolved in acidic methanol/water. Residues of alpha-cypermethrin were determined by high performance liquid chromatography (HPLC) with tandem mass spectrometry (LC-MS/MS).

Table 6.3.2-10: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in leafy cabbage

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Leaves	0.01	2	89.5	-	-
	0.10	1	83	-	-
	1.0	1	97	-	-
	0.01-1.0 mg/kg	4	89.8	9.0	10.0

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.2-11, detailed residue levels are shown in Table 6.3.2-12 and Table 6.3.2-13.
After one application at 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in leafy cabbage leaves were 0.26 mg/kg. Residues declined to levels between 0.18-0.26 mg/kg, 0.15-0.22 mg/kg and 0.074-0.17 mg/kg at 3-4, 7-8 and 14-15 days after application.

After two applications at 0.0125 kg alpha-cypermethrin/ha, initial residues ranged between 0.47 mg/kg and 0.48 mg/kg. Residues declined to levels between 0.35-0.59 mg/kg, 0.21-0.35 mg/kg and 0.19-0.24 mg/kg at 3-4, 7-8 and 14-15 days after application.

After a single application at 0.025 g a.s./ha, initial residues of alpha-cypermethrin in leafy cabbage ranged between 0.066 mg/kg and 0.13 mg/kg. Residues declined to levels between 0.046-0.056 mg/kg, 0.011-0.056 mg/kg and <0.01-0.011 mg/kg at 3, 6-7 and 14 days after application

No residues above the LOQ were found in any of the untreated samples.

2 Growth stage at respective sampling

III. CONCLUSION

After the last of two applications of BAS 310 40 I at a target rate of 0.0125 kg alpha-cypermethrin/ha, initial residues of alpha-cypermethrin ranged between 0.47 mg/kg and 0.48 mg/kg. Residues declined to levels between 0.35-0.59 mg/kg at 3-4 days after the last application.

After a single application of BAS 310 40 I at a target rate of 0.025 g a.s./ha, initial residues of alpha-cypermethrin in leafy cabbage ranged between 0.066 mg/kg and 0.13 mg/kg. Residues declined to levels between 0.046-0.056 mg/kg and 0.011-0.056 mg/kg at 3 and 6-7 days after application, respectively.

Residue behaviour of Alpha-Cypermethrin in/on fennel (bulbs formed by leafs stems), curly kale (leaves), blanched celery (stems) and spinach (leaves) outdoor after application of Fastac SC Super Contact (SC, 100 g/L) in Germany, 2006
2007/1035745
Guidelines: none
GLP: yes
(certified by Bayerisches Landesamt fuer Arbeitsschutz, Arbeitsmedizin und Sicherheitstechnik, Muenchen, Germany)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 41 I
Lot/Batch #: not reported (BAS 310 41 I, 100 g/L alpha-cypermethrin, SC)
Purity: not relevant
CAS#: alpha-cypermethrin: 67375-30-8
Development code: not applicable
Spiking levels: 0.01-0.1 mg/kg

2. Test Commodity:

Crop: Curly kale
Type: Brassica vegetables
Variety: Kobold, Winterbor, Winnetou
Botanical name: *Brassica oleracea* var. *sabellica* L.
Crop parts(s) or processed commodity: Leaves
Sample size: min. 0.5 kg

B. STUDY DESIGN

1. Test procedure

During the growing season 2006 residue decline, shortened decline and harvest trials, were performed in fennel (bulbs formed by leaf stems), curly kale (leaves), blanched celery (stems) and spinach (leaves) as field trials on several sites in Germany.
Fastac SC Super Contact (alpha-cypermethrin, SC 100) was applied foliar 2 times at rates of 0.125 L product per hectare (12.5 g/ha alpha-cypermethrin) during growing season. The trials were conducted in order to determine the magnitude of the residues of the active ingredients in or on fennel (bulbs formed by leaf stems), curly kale (leaves), blanched celery (stems) and spinach (leaves). The samples were collected 0 - 7 -10 -14 (decline curves), 0 - 7 -14 (shortened decline study) and 14 days (harvest trials) after last application, respectively.

Table 6.3.2-14: Target application rates and timings for curly kale

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2006	4	2	F	BAS 310 41 I (SC)	alpha-cypermethrin	0.0125	600-900	n.r.

n.r. = not reported

2. Description of analytical procedures

The samples were analysed for alpha-cypermethrin with modified method DFG S19. The limit of quantification (LOQ) was 0.010 mg/kg (alpha-cypermethrin).
Average recoveries from untreated samples, fortified with alpha-cypermethrin were 69 -105 % in fennel and 74 - 92 % in curly kale at fortification levels between 0.01 mg/kg and 0.10 mg/kg. In blanched celery the recoveries were 75 - 110 % at fortification levels between 0.01 mg/kg and 0.5 mg/kg. In spinach the recoveries were 90 - 100 % at fortification levels between 0.01 mg/kg and 1.0 mg/kg.
Alpha-cypermethrin: the samples were analysed for alpha-cypermethrin by the method DFG S 19 modified. The samples are extracted with acetone/water 2+1 (v+v) with subsequent extraction with cyclohexane/ethyl acetate 1+1 (v+v) and partition into acetone/cyclohexane/ethyl acetate. The extracts are cleaned up by gel permeation cbromatography on a Bio Beads SX-3 column followed by a silica gel fractionation. The residues are determined by gas chromatography using an electron capture detector. The quantification is done by external standardisation. The residues are not corrected for the recovery rates.

Table 6.3.2-15: Summary of recoveries of alpha-cypermethrin in curly kale leaves

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
DFG S 19 (modified)		**alpha-cypermethrin**			
curly kale leaves	**0.01 / 0.1 / 1.0**	**8**	**80**	**6**	**7**

II. RESULTS AND DISCUSSION

In context of this summary, only the results of alpha-cypermethrin for curly kale are reported. Residues of alpha-cypermethrin were at 0 DALA in leaves of curly kale in the range of 0.24 to 0.62 mg/kg. At 7 DALA, they ranged between 0.07 and 0.26 mg/kg, at 10 DALA they were again lower with values between 0.09 and 0.24 mg/kg. Finally, at 14 DALA they were in the range of 0.05 to 0.19 mg/kg.

Table 6.3.2-16: Summary of residues of BAS 310 I in curly kale from trials according to critical GAP after application of BAS 310 41 I

1 Days after last application
2 Growth stage at respective sampling

III. CONCLUSION

Immediately after the last of two applications of SC-formulation BAS 310 41 I at rates of 0.0125 kg alpha-cypermethrin/ha, residues in curly kale leaves were in the range of 0.24 to 0.62 mg/kg. Residues declined to 0.07-0.26 mg/kg and 0.09-0.24 mg/kg at 7±1 and 10±1 days after the last application, respectively.

Report: CA 6.3.2/4
Schneider D., 2008a
Determination of the residues of alpha-Cypermethrin in curly kale (leaves) and little radish (tuber)
2014/1083417
Guidelines: none
GLP: yes
(certified by Bayerisches Landesamt fuer Arbeitsschutz, Arbeitsmedizin und Sicherheitstechnik, Muenchen, Germany)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: BAS 310 41 I
Lot/Batch #: not reported (BAS 310 41 I, 100 g/L alpha-cypermethrin, SC)
Purity: not relevant
CAS#: alpha-cypermethrin: 67375-30-8
Development code: not applicable
Spiking levels: 0.01-0.5 mg/kg

2. Test Commodity:

Crop: Curly kale
Type: Brassica vegetables
Variety: Winnetou, Winterboer, Westländer
Botanical name: *Brassica oleracea* var. *sabellica* L.
Crop parts(s) or processed commodity: Leaves
Sample size: min. 1.0 kg

B. STUDY DESIGN

1. Test procedure

During the growing season 2007, four residue decline trials in curly kale and two residue decline trials in radish were conducted as field trials on several sites in Germany.
Fastac SC Super Contact (alpha-cypermethrin, SC 100) was applied foliar 2 times at rates of 0.125 L product per hectare (12.5 g/ha alpha-cypermethrin) during the growing season. The trials were conducted in order to determine the magnitude of the residues of the active ingredients in or on curly kale (leaves) and radish (tubers). In case of curly kale, specimens were sampled at 0, 7, 10 and 14 DALA, in case of radish samples were taken at 0, 3 and 7 DALA.

Table 6.3.2-18: Target application rates and timings for curly kale

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2007	4	2	F	BAS 310 41 I (SC)	alpha-cypermethrin	0.0125	600	n.r.

n.r. = not reported

2. Description of analytical procedures

The samples were analysed for alpha-cypermethrin with modified method DFG S19. The limit of quantification (LOQ) was 0.010 mg/kg (alpha-cypermethrin).
Recoveries from untreated samples, fortified with alpha-cypermethrin were between 70 and 93% in curly kale and between 81 and 105% in radish at fortification levels between 0.01 mg/kg and 0.5 mg/kg.
Alpha-cypermethrin: the samples were analysed for alpha-cypermethrin by the method DFG S 19 modified. The samples are extracted with acetone/water 2+1 (v+v) with subsequent extraction with cyclohexane/ethyl acetate 1+1 (v+v) and partition into acetone/cyclohexane/ethyl acetate. The extracts are cleaned up by gel permeation cbromatography on a Bio Beads SX-3 column followed by a silica gel fractionation. The residues are determined by gas chromatography using an electron capture detector. The quantification is done by external standardisation. The residues are not corrected for the recovery rates.

Table 6.3.2-19: Summary of recoveries of alpha-cypermethrin in curly kale leaves

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
DFG S 19 (modified)		alpha-cypermethrin			
curly kale leaves	0.01 / 0.02 / 0.1 / 0.5	11	81.5	6.8	8.4

II. RESULTS AND DISCUSSION

In context of this summary, only the results of alpha-cypermethrin for curly kale are reported. Residues of alpha-cypermethrin were at 0 DALA in leaves of curly kale in the range of 0.18 to 0.58 mg/kg. At 7 DALA, they ranged between 0.05 and 0.34 mg/kg, at 10 DALA they were on a comparable level with values between 0.07 and 0.34 mg/kg. Finally, at 14 DALA they were in the range of 0.03 to 0.26 mg/kg.

Table 6.3.2-20: Summary of residues of BAS 310 I in curly kale from trials according to critical GAP after application of BAS 310 41 I

Region	Year	Application	DALA[1]	Growth stage[2] BBCH	Residues Found (mg/kg)	
					Matrix	Alpha-Cypermethrin (BAS 310 I)
N-EU	2007	BAS 310 41 I (SC) 2 x 0.0125 kg a.s./ha	0	44-49	leaves	0.18 - 0.58
			7±1	45-49	leaves	0.05 - 0.34

			14±1	45-49	leaves	0.03 - 0.26

1 Days after last application
2 Growth stage at respective sampling

III. CONCLUSION

Immediately after the last of two applications of SC-formulation BAS 310 41 I at rates of 0.0125 kg alpha-cypermethrin/ha, residues in curly kale leaves were in the range of 0.18 to 0.58 mg/kg. Residues declined to 0.05-0.34 mg/kg and 0.07-0.34 mg/kg at 7±1 and 10±1 days after the last application, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

1.

Test Material:	Alpha-Cypermethrin BAS 31055I
Description:	BAS 310 55 I (ME)
Lot/Batch #:	101198: 50 g/L nominal
Purity:	not reported
CAS#:	67375-30-8 (alpha-cypermethrin)
Development code:	not reported
Spiking levels:	0.01, 0.1 and 8.0 mg/kg

2. **Test Commodity:**

Crop:	Chinese cabbage
Type:	Leafy brassica
Variety:	Kaboko, Guest Star, Paranlo, Manoko (Bejo)
Botanical name:	*Brassica rapa* subsp. *pekinensis*
Crop parts(s) or processed commodity:	Head with wrapper leaves
Sample size:	Head with wrapper leaves: 0 DALA: ≥0.5 kg / ≥ 12 units 3±1, 7±1, 14±1 DALA: ≥2 kg / ≥ 12 units

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2013 growing season, four field trials were conducted under field conditions in representative cabbage (Chinese) growing areas in Southern France, Greece, Italy and Spain to determine the residue level of alpha-cypermethrin (BAS 310 I) in or on Raw Agricultural Commodities (RAC).

Two foliar applications with BAS 310 55 I, an ME formulation of alpha-cypermethrin (50.0 g a.s./L), were made to plot 2 to cabbage (Chinese), at a rate of 0.25 L formulated product/ha, equal to 12.5 g alpha-cypermethrin/ha, at 14 and 6-7 day(s) before harvest (DBH). The nominal spray volume used was 200 L/ha.

Treated cabbage (Chinese) (head with wrapper leaves) specimens of trials S13-00427-01, -02 and -03 were sampled at 0 DALA, at 3 DALA, at 6-7 DALA and at 13-14 DALA.
Treated cabbage (Chinese) (head with wrapper leaves) specimens of trial S13-00427-04 were sampled at 0 DALA, at 3 DALA and at 6 DALA. As the trial site had been ploughed prior to the 14 ± 1 DALA sampling point by mistake, the 14 ± 1 DALA could not be taken.

The maximum storage interval from harvest until analysis was 368 days.

Table 6.3.2-22: Target application rates and timings for Chinese cabbage

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2013	4	2	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.0125	200	1st appl. 14, 2nd appl. 6-7 days before harvest

2. Description of analytical procedures

All Chinese cabbage specimens were analyzed for alpha-cypermethrin according to BASF analytical method no. 567/0, which determines the analytes by means of LC-MS/MS.
The residues of alpha-cypermethrin in Chinese cabbage specimens were extracted from plant matrices using a mixture of methanol / water / 2N hydrochloric acid (70:25:5, v/v/v). After centrifugation and partition of an aliquot of the extract into cyclohexane, evaporation to dryness and dissolving in methanol / water (80+20, v+v), the final determination of alpha-cypermethrin was performed by LC-MS/MS.
As a modification to optimize the recovery of alpha-cypermethrin during the liquid/liquid-partition with cyclohexane, the extract was partitioned three times in order to adapt the method to the laboratory situation.
The limit of quantitation (LOQ) was 0.01 mg/kg for alpha-cypermethrin.

Table 6.3.2-23: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in Chinese cabbage

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Chinese cabbage / Head with wrapper leaves	0.01	3	86.8	12.8	14.7
Chinese cabbage / Head with wrapper leaves	0.10	3	84.9	13.0	15.4
Chinese cabbage / Head with wrapper leaves	8.0	1	97.9	-	-
Overall		**7**	**87.6**	**11.5**	**13.2**

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.2-24. Detailed results are given in Table 6.3.2-25.

At 0 DALA the residues of alpha-cypermethrin (BAS 310 I) ranged between 0.090 mg/kg and 0.27 mg/kg. At 2-3 DALA the residues of alpha-cypermethrin (BAS 310 I) ranged between 0.019 mg/kg and 0.11 mg/kg. At 6-7 DALA residues between 0.013 mg/kg and 0.041 mg/kg of alpha-cypermethrin (BAS 310 I) were found. At 13-14 DALA the residues of alpha-cypermethrin (BAS 310 I) ranged between <0.01 mg/kg (below the LOQ) and 0.027 mg/kg.
No residues of alpha-cypermethrin (BAS 310 I) above the LOQ were found in the untreated specimens of this study. ~~, with the exception of sample L1300490001 of trial S13-00427-04 (L130049), taken at 0 DALA, where an alpha-cypermethrin (BAS 310 I) residue of 0.018 mg/kg was detected. The source of the contamination has not been determined. Taking into account the corresponding residues in the treated specimens the residue in the control sample had no impact on the study.~~

III. CONCLUSION

Immediately after the last of two applications of alpha-cypermethrin at a target rate of 0.0125 g a.s./ha, the residues of alpha-cypermethrin in Chinese cabbage ranged between 0.090 mg/kg and 0.27 mg/kg. At 2-3 days after the last application the residues of alpha-cypermethrin (BAS 310 I) ranged between 0.019 mg/kg and 0.11 mg/kg.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31040I

Description:	BAS 310 40 I (SC)
Lot/Batch #:	1171: 100 g/L
Purity:	not reported
CAS#:	67375-30-8
Development code:	not reported
Spiking levels:	0.01, 1.0 and 2.0 mg/kg

2. Test Commodity:

Crop:	Lettuce, head
Type:	Leafy vegetable
Variety:	Estelle, Little Gem, Tamburo, Nobilan, Sagesse, Gentilina, Filipus, Atraxion
Botanical name:	*Lactuca sativa*
Crop parts(s) or processed commodity:	Heads
Sample size:	12 units (min 1.0 kg)

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2005 growing season, eight field trials were conducted in head lettuce in France (Northern and Southern European region), Germany, Greece, Italy, Spain, the Netherlands and the United Kingdom.
In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to head lettuce plants on separate plots either once or twice at a target rate of 0.0125 kg alpha-cypermethrin/ha in a nominal spray volume of 400 L/ha.

In four trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to head lettuce plants once at a target rate of 0.025 kg alpha-cypermethrin/ha in an nominal spray volume of 400 L/ha.

Specimens of lettuce heads were collected immediately after the last application from each plot, as well as 2-3, 7-8 and 14-15 days thereafter.

Samples were stored frozen at or below -10°C for a maximum of 501 days until analysis.

Table 6.3.3-4: Target application rates and timings for lettuce

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing

		2	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	400	1st appl. 14 ±1, 2nd appl. 7 ±1 days before harvest
	4	1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.025	400	7 ±1 days before harvest

2. Description of analytical procedures

Specimens were analysed using BASF analytical method No. 567/0, determines the underivatised cypermethrin by means of HPLC-MS/MS.
Principle of the method:
Residues of cypermethrin (alpha-cypermethrin or cypermethrin) are extracted with a mixture of methanol/water/2N hydrochloric acid (70:25:5). After centrifugation, an aliquot of the extract is cleaned by liquid/liquid partition against cyclohexane. The residues are further purified (if needed) using a silica gel solid phase extraction (SPE) column. The final determination of total cypermethrin residues is performed by HPLC-MS/MS, monitoring the ion transition from m/z 433.2 / 191.1 (the ammonium adduct of cypermethrin).
The limit of quantitation (LOQ) of the method for alpha-cypermethrin is 0.01 mg/kg.

Table 6.3.3-5: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in lettuce

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
head	0.01	3	88.4	13.0	15
	1.0	2	91.2	-	-
	2.0	1	86.8	-	-
	Overall	6	89	8	9

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.3-6, detailed residue levels are shown in Table 6.3.3-7 and Table 6.3.3-8.
After one application at a target rate of 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.282 mg/kg and 0.421 mg/kg. Residues declined to levels between 0.117-0.382 mg/kg, 0.042-0.243 mg/kg and <0.01-0.194 mg/kg at 2-3, 7 and 14 days after application.

After two applications at a target rate of 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.315 mg/kg and 0.654 mg/kg. Residues declined to levels between 0.125-0.722 mg/kg, 0.052-0.491 mg/kg and <0.01-0.412 mg/kg at 2-3, 7 and 14 days after application.

After a single application at a target rate of 0.025 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.299 mg/kg and 1.161 mg/kg. Residues declined to levels between 0.103-0.585 mg/kg, 0.062-0.520 mg/kg and 0.013-0.112 mg/kg at 3, 7-8 and 14-15 days after application.

In the control specimens, no residues of total cypermethrin above the limit of quantitation were found.

III. CONCLUSION

After two applications of alpha-cypermethrin at a target rate of 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.315 mg/kg and 0.654 mg/kg which declined to levels between 0.125-0.722 mg/kg and 0.052-0.491 mg/kg at 2-3 and 7 days, respectively, after the last application.

After a single application of alpha-cypermethrin at a target rate of 0.025 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.299 mg/kg and 1.161 mg/kg. Residues declined to levels between 0.103-0.585 mg/kg and 0.062-0.520 mg/kg at 3 and 7-8 days, respectively, after application.

Oxspring S., 2007a
Study on the residue behaviour of Alpha-Cypermethrin in head lettuce after treatment with BAS 310 40 I or BAS 310 08 I under field conditions in Northern and Southern Europe during 2006
2007/1007938
Guidelines: none
GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31040I, BAS 31008I

Description:	BAS 310 40 I (EC), BAS 310 08 I (WG)
Lot/Batch #:	1171, BAS 310 40 I, Alpha-Cypermethrin: 100 g/L; 40000, BAS 310 08 I, Alpha-Cypermethrin: 150 g/kg
Purity:	not reported
CAS#:	67375-30-8
Development code:	not reported
Spiking levels:	0.01, 1.0 and 2.0 mg/kg

2. Test Commodity:

Crop:	Lettuce, head
Type:	Leafy vegetable
Variety:	Jambis, Igoma, Filipo, Gentilina
Botanical name:	*Lactuca sativa*
Crop parts(s) or processed commodity:	Heads
Sample size:	1.0 kg/12 units

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2006 growing season, four field trials were conducted in representative head lettuce growing areas in the United Kingdom, France, Spain and Italy to determine the residue level of alpha-cypermethrin in or on Raw Agricultural Commodities (RAC).

Trials AF/10503/BA/1 and 2 (France and the United Kingdom) consisted of four treated plots. Two plots were treated with BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g a.s./L). The test item was foliar applied at a rate of 0.125 L of formulated product/ha either once 7 days before expected harvest (plot 2) or twice 14 and 7 days before expected harvest (plot 3). Two further plots were treated with BAS 310 08 I, a WG formulation of alpha-cypermethrin (150 g a.s./kg). The test item was foliar applied at a rate of 0.08 kg of formulated product /ha either once 7 days before expected harvest (plot 4) or twice 14 and 7 days before expected harvest (plot 5).
Trials AF/10503/BA/3 and 4 (Italy and Spain) consisted of two treated plots. One plot was treated with BAS 310 40 1, an EC formulation of alpha-cypermethrin (100 g a.s./L), foliar applied at a rate of 0.25 L of formulated product /ha, 7 days before expected harvest (plot 2). A second plot was treated with BAS 310 08 I, a WG formulation of alpha-cypermethrin (150 g a.s./kg), foliar applied at a rate of 0.16 kg of formulated product /ha, 7 days before expected harvest (plot 3). The nominal spray volume used was 400 L/ha at all applications and all application timings were made within ± 1 day of that specified in the study plan.
Specimens of lettuce heads were collected immediately after the last application (0 DALA) from each plot as well as 2-3, 6-7 and 14 days thereafter.

Generally the specimens were frozen within 24 hours of being taken, and remained frozen at or below -18°C, including during transportation, until analysis.
The maximum storage interval from sample collection until extraction was 225 days.

Table 6.3.3-9: Target application rates and timings for lettuce

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2006	2	1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	400	7 ±1 days before harvest
		1	F	BAS 310 08 I (WG)	alpha-cypermethrin	0.0125	400	7 ±1 days before harvest
		2	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	400	1st appl. 14 ±1, 2nd appl. 7 ±1 days before harvest
		2	F	BAS 310 08 I (WG)	alpha-cypermethrin	0.0125	400	1st appl. 14 ±1, 2nd appl. 7 ±1 days before harvest
	2	1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.025	400	7 ±1 days before harvest
		1	F	BAS 310 08 I (WG)	alpha-cypermethrin	0.025	400	7 ±1 days before harvest

2. Description of analytical procedures

For the analysis of alphacypermethrin, BASF method No. 567/0 was applied which determines the underivatised cypermethrin by means of HPLC-MS/MS.

Principle of method:
Residues of cypermethrin (alphacypermethrin or cypermethrin) are extracted with a mixture of methanol/water/2N hydrochloric acid (70:25:5). After centrifugation, an aliquot of the extract is cleaned by liquid/liquid partition against cyclohexane. The residues are further purified (if needed) using a silica gel solid phase extraction (SPE) column. The final determination of total cypermethrin residues is performed by HPLC-MS/MS, monitoring the ion transition from m/z 433.2 / 191.1 (the ammonium adduct of cypermethrin).

The limit of quantitation (LOQ) of the method for alpha-cypermethrin is 0.01 mg/kg.

Table 6.3.3-10: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in lettuce

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Head	0.01	3	90.2	5.3	5.9
	1.0	1	96.1	-	-
	2.0	1	98.0	-	-
	0.01-2.0	5	92.9	5.3	5.7

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.3-11, detailed residue levels are shown in Table 6.3.3-12 and Table 6.3.3-13.
After one application at a target rate of 0.0125 kg alpha-cypermethrin/ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.024 mg/kg and 0.131 mg/kg. Residues declined to levels between <0.01-0.036 mg/kg, <0.01-0.19 mg/kg and <0.01 mg/kg at 3, 7 and 14 days after application.

After two applications at a target rate of 0.0125 kg alpha-cypermethrin/ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.090 mg/kg and 0.193 mg/kg. Residues declined to levels between <0.01-0.072 mg/kg, <0.01-0.022 mg/kg and <0.01 mg/kg at 3, 7 and 14 days after application.

After one application at a target rate of 0.025 kg alpha-cypermethrin/ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.228 mg/kg and 0.512 mg/kg. Residues declined to levels between 0.139-0.387 mg/kg, 0.035-0.131 mg/kg and <0.01-0.013 mg/kg at 3, 7 and 14 days after application.

No difference in the residue levels was observed after application of the EC or the WG formulation. In the control specimens, no residues of total cypermethrin above the limit of quantitation were found.

III. CONCLUSION

After two applications of alpha-cypermethrin at a target rate of 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.090 mg/kg and 0.193 mg/kg. Residues declined to levels between <0.01-0.072 mg/kg and <0.01-0.022 mg/kg at 3 and 7 days, respectively, after application.

After one application of alpha-cypermethrin at a target rate of 0.025 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.228 mg/kg and 0.512 mg/kg. Residues declined to levels between 0.139-0.387 mg/kg and 0.035-0.131 mg/kg at 2-3 and 6-7 days, respectively, after application.

No difference in the residue levels was observed after application of the EC or the WG formulation.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31040I
Description: BAS 310 40 I (EC)
Lot/Batch #: 1171, Alpha-Cypermethrin: 100 g/L
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01, 0.1 and 1.0 mg/kg

2. Test Commodity:
Crop: Lettuce, head
Type: Leafy vegetable
Variety: Lucan, mixture of Dynnmite and Dolly, Matilda, Pinochio, Soleilan, Filippus, Carinos, Aberam
Botanical name: *Lactuca sativa*
Crop parts(s) or processed commodity: Head
Sample size: min. 2 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2006 growing season, eight field trials were conducted in head lettuce in Denmark, France (Northern and Southern European region), Germany, Greece, Italy, Spain and the United Kingdom.
In four trials located in the Northern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to head lettuce plants on separate plots either once or twice at a target rate of 125 mL/ha, equivalent to 0.0125 kg alpha-cypermethrin/ha. The spray volume targeted 400 L/ha.

In four trials located in the Southern European region, an emulsifiable concentrate formulation of alpha-cypermethrin (EC 100 g a.s./L; BAS 310 40 I), was foliar applied to head lettuce plants once at a target rate of 250 mL/ha, equivalent to 0.025 kg alpha-cypermethrin/ha in a target spray volume of 400 L/ha.
The actual application rates were within 10% of the nominal values presented below with the exception of single application on plot 102 and second application on plot 103 of trial A/GE/I/06/107 which deviated by 15-16% less from target amount.
Specimens of lettuce heads were collected immediately after the last application from each plot, as well as 2-4, 7-8 and 13-14 days thereafter.
Samples were stored frozen at or below -18°C for a maximum of 156 days until analysis below -18°C, including during transportation, until analysis. Only for short periods of time storage temperature peaks higher than -18°C occured - mainly caused by sample handling that did not affect the samples.

Table 6.3.3-14: Target application rates and timings for lettuce

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2006	4	1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	400	7 ±1 days before harvest
		2	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.0125	400	1st appl. 14 ±1, 2nd appl. 7 ±1 days before harvest
	4	1	F	BAS 310 40 I (EC)	alpha-cypermethrin	0.025	400	7 ±1 days before harvest

2. Description of analytical procedures

Specimens were analysed using BASF analytical method No. 567/0.
Residues of alpha-cypermethrin were extracted from head lettuce (head) using methanol/water and hydrochloric acid. An aliquot of the extract was centrifuged and partitioned against cyclohexane/water. The cyclohexane phase was evaporated and the residue was dissolved in acidic methanol/water. Residues of alpha-cypermethrin were determined by high performance liquid chromatography (HPLC) with tandem mass spectrometry (LC-MS/MS). The validated sensitivity (LOQ, limit of quantitation) of the method was 0.01 mg/kg.

Table 6.3.3-15: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in lettuce

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Head	0.01	4	96	12	12
	0.1	3	92	2	2
	1.0	1	100	-	-
	Overall	8	95	8	9

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.3-16, detailed residue levels are shown in Table 6.3.3-17 and Table 6.3.3-18.
After one application at a target rate of 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.024 mg/kg and 0.38 mg/kg. Residues declined to levels between 0.014-0.13 mg/kg, <0.01-0.080 mg/kg and <0.01-0.025 mg/kg at 2-3, 7 and 13-14 days after application.

After two applications at a target rate of 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.030 mg/kg and 0.350 mg/kg. Residues declined to levels between 0.021-0.27 mg/kg, <0.01-0.12 mg/kg and <0.01-0.039 mg/kg at 2-3, 7 and 13-14 days after application.

After a single application at a target rate of 0.025 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.24 mg/kg and 1.1 mg/kg. Residues declined to levels between <0.01-0.41 mg/kg, <0.01-0.12 mg/kg and <0.01-0.031 mg/kg at 3-4, 7-8 and 13-14 days after application.
No residues of alpha-cypermethrin above the LOQ were found in the untreated specimens of head lettuce.

III. CONCLUSION

After two applications of alpha-cypermethrin at a target rate of 0.0125 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.030 mg/kg and 0.350 mg/kg. Residues declined to levels between 0.021-0.27 mg/kg and <0.01-0.12 mg/kg at 2-3 and 7 days, respectively, after the last application.

After a single application of alpha-cypermethrin at a target rate of 0.025 kg a.s./ha, initial residues of alpha-cypermethrin in lettuce heads ranged between 0.24 mg/kg and 1.1 mg/kg. Residues declined to levels between <0.01-0.41 mg/kg and <0.01-0.12 mg/kg at 3-4 and 7-8 days, respectively, after application.

Klimmek S.,Gizler A., 2014a
Study on the residue behaviour of Alpha-Cypermethrin (BAS 310 I) in lettuce (open leaf varieties) after two applications with BAS 310 55 I under field conditions in Southern France, Greece, Italy and Spain, 2013
2014/1140312
Guidelines: none
GLP: yes
(certified by Freie und Hansestadt Hamburg, Behoerde fuer Soziales, Familie, Gesundheit und Verbraucherschutz, Hamburg, Germany)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198, BAS 310 55 I, Alpha-Cypermethrin: 50 g/L;
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01, 0.1 and 4.0 mg/kg

2. Test Commodity:
Crop: Lettuce, open leaf
Type: Leafy vegetable
Variety: Kirina, Parris Island, Foglia di Quercia, Flavius, Ukulele, Magister F1, Analena, Filipo
Botanical name: *Lactuca sativa* var. *crispa*
Crop parts(s) or processed commodity: Heads
Sample size: 0 DALA: ≥ 0.5 kg / ≥ 12 units
1 DALA and later: ≥ 1 kg / ≥ 12 units

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2013 growing season, eight residue trials were conducted under field conditions in representative lettuce growing areas in Southern France, Greece, Italy and Spain to determine the residue level of alpha-Cypermethrin (BAS 310 I) in or on Raw Agricultural Commodities (RAC).

Two foliar applications with BAS 310 55 I, an ME formulation of alpha-Cypermethrin (50.0 g ai/L), were made to plot 2 to lettuce, at a rate of 0.25 L formulated product/ha, equal to 12.5 g alpha-Cypermethrin/ha, at 7 and 1 day(s) before harvest (DBH). The nominal spray volume used was 200 L/ha.
Untreated lettuce (head) specimens were sampled immediately pre application at 0 days before the last application (DBLA) and at 1, 2-3 and 6-8 days after last application (DALA).
Treated lettuce (head) specimens were sampled at 0 DALA and at 1, 2-3 and 6-8 DALA.
Generally the specimens were frozen within 12 hours of being taken, and remained frozen at or below -18°C, including during transportation, until analysis. The maximum storage interval from harvest until analysis of alpha-cypermethrin (BAS 310 I) was 320 days.

Table 6.3.3-19: Target application rates and timings for lettuce

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2013	8	2	F	BAS 310 55 I	alpha-cypermethrin	0.0125	200	7±1 days and 1 day before harvest

2. Description of analytical procedures

All lettuce specimens were analyzed for alpha-cypermethrin according to BASF analytical method no. 567/0, which determines the analytes by means of LC-MS/MS.
Principle of method: Samples are extracted with methanol/water/2N hydrochloric acid (70/25/5, v/v/v). After centrifugation and partition of an aliquot of the extract into cyclohexane, the samples are evaporated to dryness and dissolved in methanol / water (80+20, v+v).

The final determination of the analyte in the untreated and treated specimens was performed by single extraction and single injection with liquid chromatography and mass spectrometric detection (LC-MS/MS).
The limit of quantitation (LOQ) was 0.010 mg/kg for alpha-cypermethrin.

Table 6.3.3-20: Summary of recoveries for alpha-cypermethrin in lettuce

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (±)	RSD (%)
BASF Method No. 567/0		**alpha-cypermethrin (BAS 310 I)**			
Lettuce (head)	0.01	5	92.8	9.3	10.0
	0.10	5	86.9	8.6	9.9
	4.0	1	84.5	-	-
	Overall	11	89.4	8.7	9.7

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.3-21, detailed residue levels are shown in Table 6.3.3-22.

At 0 DALA the residues of alpha-cypermethrin (BAS 310 I) ranged between 0.063 mg/kg and 0.44 mg/kg. At 1 DALA (PHI) the residues of alpha-cypermethrin (BAS 310 I) ranged between 0.058 mg/kg and 0.42 mg/kg. At 3 DALA the residues of alpha-cypermethrin (BAS 310 I) ranged between 0.032 mg/kg and 0.24 mg/kg. At 7 DALA residues between 0.012 mg/kg and 0.094 mg/kg of alpha-cypermethrin (BAS 310 I) were found.
No residues above the LOQ of alpha-cypermethrin (BAS 310 I) were found in the untreated specimens of this study, except for the specimens of trial S13-00444-01 (L130050) taken at 0, 1 and 3 DALA.
In the untreated specimens of trial S13-00444-01 (L130050) taken at 0, 1 and 3 DALA, residues between 0.025 mg/kg and 0.027 mg/kg of alpha-cypermethrin (BAS 310 I) were found. The source of the contamination has not been determined. Taking into account the corresponding residues in the treated specimens the residues in the control samples had no impact on the study.

Table 6.3.3-21: Summary of residues in lettuce after application of BAS 310 55 I

Region	Year	No. of Appl.	Application	DALA[1]	Growth stage[2] BBCH	Range of Residues (mg/kg)

2 Growth stage at respective sampling

III. CONCLUSION

Immediately after the last of two applications of the formulation BAS 310 55 I (ME) at a target rate of 0.0125 kg a.s./ha per application to open leaf lettuce varieties under field conditions in Southern Europe, residues of alpha-cypermethrin ranged between 0.063 mg/kg and 0.44 mg/kg. At 1 day after the last application, the residues of alpha-cypermethrin ranged between 0.058 mg/kg and 0.42 mg/kg and at 2-3 days after the last application the residues ranged between 0.032 mg/kg and 0.24 mg/kg.

The studies not yet evaluated are summarized in the following chapter.

Report: CA 6.3.4/1
Oxspring S., 2008a
Study on the residue behaviour of Alpha-Cypermethrin in oilseed rape after treatment with BAS 310 40 I under field conditions in Northern and Southern Europe during 2007
2008/1019999
Guidelines: none
GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31040I
Description: BAS 310 40 I (SC)
Lot/Batch #: 1209: 100 g/L nominal
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01-1.0 mg/kg

2. Test Commodity:
Crop: Oilseed rape
Type: Oilseeds
Variety: Adriana, Robuste, Corail, Standy
Botanical name: *Brassica napus*
Crop parts(s) or processed commodity: Whole plant w/o root, whole pods, seed
Sample size: 12 units/1.0 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2007 growing season, a total of six field trials were conducted on oilseed rape in order to determine the residue level of BAS 310 I in or on raw agricultural commodities (RAC). Trial AF/12151/BA/1 (L070763) in the UK was destroyed by the grower after the second sampling timing and was abandoned and Trial AF/121511BA/4 (L070766) in the UK was erroneously treated with the insecticide lambda-cyhalothrin. Due to these unexpected issues, only results from the remaining four winter oilseed rape trials were used for evaluation.
BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g a.s./L), was applied at a rate of 0.0105 kg alpha-cypermethrin/ha at each application in a spray volume of 300 L/ha. Applications were made at 10 day intervals approximately 31±1 and 21±1 days before expected harvest.

Whole plant specimens were collected immediately after the last application (0 DALA) from each plot at all trials. Oilseed rape seed was sampled at 14±1, 21±1 and 28±1 days after last application (DALA) at all the trials with the exception for Trial AF/12151/BA/3 where whole pods were sampled 14±1 DALA due to immaturity of the crop.
Generally the specimens were frozen within 24 hours of being taken, and remained frozen at or below -18°C, including during transportation, until analysis.
The maximum storage interval from harvest until analysis was 252 days.

Table 6.3.4-4: Target application rates and timings for oilseed rape

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (g a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2007	4	2	F	BAS 310 40 I	alpha-cypermethrin	10.5	300	1st appl. 21±1, 2nd appl. 31±1 days before harvest

2. Description of analytical procedures

Alpha-cypermethrin was extracted from specimens according to an adaption of BASF Method No. 567/0 (L0020/01). The extracts were analysed for alpha-cypermethrin using BASF Method No. 567/1 (L0071/01), which quantifies the analyte with a limit of quantitation (LOQ) of 0.01 mg/kg. BAS 310 I was extracted with a 95:5 methanol/hydrochloric acid mixture (solvent II of method 567/1). After centrifugation, an aliquot of the extract was partitioned twice into cyclohexane. The final determination was according to BASF method 567/0 with HPLC-MS/MS.

Table 6.3.4-5: Summary of recoveries for alpha-cypermethrin in oilseed rape

Matrix	Fortification Level (mg/kg)	Summary Recoveries		
		n	Mean (%)	RSD (%)
BASF Method No. 567/0		alpha-cypermethrin (BAS 310 I)		
whole plant w/o root, whole pods, seed	0.01/0.10/1.00	8	102	10

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.4-6, detailed residue levels are shown in Table 6.3.4-7 and Table 6.3.4-8.

No residues of alpha-cypermethrin at or above the LOQ were detected in the untreated specimens. Directly after the last application, alpha-cypermethrin ranged between 0.109 mg/kg and 0.390 mg/kg in oliseed rape whole plants. Approximately two weeks later, residues of alpha-cypermethrin were between <0.01 mg/kg and 0.012 mg/kg in seed, and 0.098 mg/kg in whole pods. At the intended harvest (21±1 DALA), no residues of alpha-cypermethrin above the limit of quantitation (0.01 mg/kg) were found in seed.

Table 6.3.4-6: Summary of residues in oilseed rape after application of BAS 310 40 I

1 Days after last application
2 Growth stage at respective sampling

III. CONCLUSION

No residues of alpha-cypermethrin above the limit of quantitation (0.01 mg/kg) were found in rape seed at 21 days or later after the last of two applications of BAS 310 40 I at a target rate of 0.0105 kg a.s./ha.

I. MATERIAL AND METHODS

A. MATERIALS

1. **Test Material:** Alpha-Cypermethrin BAS 31051I, BAS 31040I
Description: BAS 310 51 I (ME)
BAS 310 40 I (SC)
Lot/Batch #: 101156, BAS 310 51 I, Alpha Cypermethrin: 50.0 g/L; 1209, BAS 310 40 I, Alpha Cypermethrin: 100.0 g/L
Purity: not reported
CAS#: 67375 30 8
Development code: not reported
Spiking levels: 0.01 1.00 mg/kg

2. **Test Commodity:**
Crop: Oilseed rape
Type: Oilseed
Variety: Elektra, Campo, Fantasio, Kabel
Botanical name: *Brassica napus*
Crop parts(s) or processed commodity: Whole plant, pods with seed, seed
Sample size: 0.5 1.0 kg

B. STUDY DESIGN AND METHODS

1. **Test procedure**

During the 2008 growing season, a total of four open field trials were conducted in rape in Germany, Northern France, Italy and Spain.
The objective of the study was to determine the magnitude of alpha-cypermethrin residues in rape after application of the formulations BAS 310 51 I (ME formulation) and BAS 310 40 I (EC formulation). The additional objective was the comparison of the residue levels after the application of the EC and the ME formulation. Each field trial consisted of three plots:
Trials L080185 (Germany) and L080186 (Northern France):

Plot 1: Control
Plot 2: Treated twice with 0.3 L/ha of BAS 310 51 I (15.0 g/ha of BAS 310 I, ME formulation)
Plot 3: Treated twice with 0.15 L/ha of BAS 310 40 I (15.0 g/ha of BAS 310 I, EC formulation)
Trials L080187 (Italy) and L080188 (Spain):
Plot 1: Control
Plot 2: Treated once with 0.6 L/ha of BAS 310 51 I (30.0 g/ha of BAS 310 I, ME formulation)
Plot 3: Treated once with 0.3 L/ha of BAS 310 40 I(30.0 g/ha of BAS 310 I, EC formulation)
The applications took place 30-31 days before harvest (DBH) and 20-22 DBH on trials L080185 and L080186 and 21 DBH on trials L080187 and L080188 with a spray volume of 300 L/ha of spray.
Both formulations were applied with the same GAP.

0 DALA (days after last application) sampling in the untreated plot was performed immediately prior to the last application of the treated plots. The treated rape specimens (whole plant and seed) were taken immediately after the last application (0 DALA). Untreated and treated specimens were additionally collected 14±1, 21±1 and 28±1 DALA.
The maximum storage interval from harvest until start of analysis was 266 days.

Table 6.3.4-9: Target application rates and timings for oilseed rape

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (g a.s./ha)	Water Volume (L/ha)	Target Date/ Timing

	4	2 1	F	BAS 310 40 I	alpha-cypermethrin	15 30	300	21±1, 31±1 days before harvest

2. Description of analytical procedures

Alpha-cypermethrin was extracted from specimens according to an adaption of BASF Method No. 567/0 (L0020/01) with a limit of quantitation (LOQ) of 0.01 mg/kg.
The residues of alpha-cypermethrin in whole plant no root specimens were extracted from plant matrices using a mixture of methanol, water and HCl (2 mol/L). For clean-up a liquid/liquid partition against cyclohexane was used. The final determination of alpha-cypermethrin was performed by LC-MS/MS.
The residues of alpha-cypermethrin in seed specimens were extracted from plant matrices using a mixture of acetonitrile and n-hexane. An aliquot of acetonitrile phase was taken. For clean-up a liquid/liquid partition against n-hexane was used. The final determination of alpha-cypermethrin was performed by LC-MS/MS.

Table 6.3.4-10: Summary of recoveries for alpha-cypermethrin in oilseed rape

Matrix	Fortification Level (mg/kg)	Summary Recoveries		
		n	Mean (%)	RSD (%)

rape (whole plant no root)	0.01-1.00	2	94	n. a.
rape (seed)	0.01-1.00	3	78	29
rape (rows/pods with seed)	0.01-1.00	2	104	n. a.

n.a. = not applicable

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.4-11, detailed residue levels are shown in Table 6.3.4-12 and Table 6.3.4-13.

Directly after the last application (0 DALA) of BAS 310 51 I (plot 2), alpha-cypermethrin residues were 0.20-0.41 mg/kg in whole plant specimens. At 13-14 days after the last application, residues were <0.01-0.02 mg/kg in rape seed and 0.05 mg/kg in pods with seed. At 20-22 and at 27-28 days after the last application, residues in seed were <0.01-0.01 mg/kg.
Directly after the last application (0 DALA) of BAS 310 40 I (plot 3), alpha-cypermethrin residues were 0.12-0.54 mg/kg in whole plant specimens. At 13-14 days after the last application residues were <0.01-0.01 mg/kg in rape seed and 0.03 mg/kg in pods with seed. At 20-22 and at 27-28 days after the last application, residues in seed were <0.01-0.01 mg/kg.

			21	88-89	seed	<0.01-0.01
			28	88-89	seed	<0.01-0.01
		BAS 310 40 I 1 x 0.0300 kg a.s./ha	0	65-75	whole plant	0.12-0.54
			14	84-87	seed	<0.01-0.01
			21	88-89	seed	<0.01
			28	88-89	seed	<0.01-0.01

1 Days after last application
2 Growth stage at respective sampling

III. CONCLUSION

At 27-28 days after the last of two applications of alpha-cypermethrin formulations at a target rate of 0.015 kg a.s./ha or after a single application at 0.03 mg a.s./ha, residues in oilseed rape seed ranged between <0.01-0.01 mg/kg.
The analytical results demonstrate that the treatment with BAS 310 51 I and BAS 310 40 I did not lead to significantly different residue levels in the raw agricultural commodity at harvest.

I. MATERIAL AND METHODS

A. MATERIALS

1. **Test Material:** Alpha-Cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198: 50.0 g/L nominal
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01-1.0 mg/kg

2. **Test Commodity:**
Crop: Oilseed rape
Type: Oilseeds
Variety: Heros, DK Exquisite, CSZ8992 + ES Alias, PR46W31, PR44W29, Kabel
Botanical name: *Brassica napus*
Crop parts(s) or processed commodity: Whole plant w/o root, whole pods, seed
Sample size: Whole plant w/o root: 0.50-2.3 (>0.50) kg
Pods with seeds: 0.51-0.96 (>0.50) kg
Seed: 0.50-1.2 (>0.50) kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2012 growing season, a total of six field trials were conducted in oilseed rape in order to determine the residue level of BAS 310 I in or on raw agricultural commodities (RAC).
The trials were performed in Northern Europe (Germany and Belgium) and in Southern Europe (France, Greece, Italy and Spain).

The trials performed in Northern Europe consisted of two plots: one untreated plot (control, plot 1) and one plot treated twice with BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha (plot 2).
In Southern Europe (France, Greece, Italy), the experimental set-up consisted of three plots: one plot untreated (plot 1), a second plot treated twice with BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha (plot 2) and a third plot treated once with BAS 310 55 I at a target rate of 0.025 kg alpha-cypermethrin/ha (plot 3). The applications were made at 28 and 20-22 days before harvest (plot 2) and at 20-22 days before harvest (plot 3) using a spray volume of 200 L/ha.
In all trials the applications were made at crop stages BBCH between 75 and 87.
For the analysis samples of rape plant (without roots) were taken directly after the last application (0 DALA). Seed and/or pod with seed specimens and rest of plant (without roots) were taken at 13-14, 20-22, and 28-29 DALA, depending on the crop maturity.
The maximum storage interval from harvest until analysis for plant samples was 416 days.
A deviation has to be noted for L120462: Two forbidden pesticides were applied on the crops before, lambda-cyhalothrin and tau-fluvalinate. With regard to the use of tau-fluvalinate and lambda-cyhalthrin, these two compounds could theoretically interfere with the analysis of alpha-cypermethrin if one of the MS transitions were identical to the Alpha-cypermethrin and were not detected. In the case of trial L120462, these two products were applied to the crop on 1st March and 26th March, whereas the trial started on 24 May, 8 to 11 weeks after the crop treatment with these two products. Reviewing the results of the control specimens collected, it is apparent, that no residue of this crop treatment was potentially interfering with the specimen analysis of the trial plots.

DBH: days before harvest

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin).
The residues of alpha-cypermethrin in rape specimens were extracted with acetonitrile/n-hexane. After centrifugation and two further partitioning steps with n-hexane, an aliquot of the extract was diluted with acetonitrile/water (80:20, v/v) for LC/MS/MS determination. Final determination was performed by LC/MS/MS using the ammonium adduct of cypermethrin.
The limit of quantitation (LOQ) of the method is 0.01 mg/kg. The mean procedural recovery in rape specimens averaged 86.3±10.6% (mean ± SD) for alpha-cypermethrin at fortification levels of 0.01-1.0 mg/kg.

Table 6.3.4-15: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in oilseed rape

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
whole plant w/o root	0.01-1.0	9	80.1	7.3	9.2
seed	0.01-1.0	6	75.8	2.5	3.3
pods with seed	0.01-1.0	6	94.3	11.3	12.0
rest of plant without roots	0.01-1.0	9	94.2	5.4	5.7

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.4-16, detailed residue levels are shown in Table 6.3.4-17 and Table 6.3.4-18.
Directly after the last of two applications of BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha, residues of BAS 310 I (alpha-cypermethrin) in whole plant (without root) specimens ranged between 0.17-0.49 mg/kg. At 13-14 days after the last application residues were 0.014-0.037 mg/kg in pods with seeds and 0.033-0.42 in rest of plant (without roots). At 20-22 DALA residues were 0.039 mg/kg in pods with seeds and 0.011-0.22 mg/kg in rest of plant (without roots). After a longer PHI (28-29 DALA), residues in rest of plant (without roots) were 0.018-0.19 mg/kg.
Residues in seeds after two treatments with BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha were below the limit of quantitation (LOQ; 0.01 mg/kg) at all sampling times (13-14, 20-22 and 28-29 DALA).
Directly after a single treatment with BAS 310 55 I at a target rate of 0.025 kg alpha-cypermethrin/ha, residues of BAS 310 I (alpha-cypermethrin) in whole plant (without root) specimens ranged between 0.25-0.44 mg/kg. At 13-14 days after application residues were 0.021-0.064 mg/kg in pods with seeds and 0.013-0.14 in rest of plant (without roots). At 20-22 DALA, and at 28-29 DALA, residues in rest of plant (without roots) were 0.010-0.17 mg/kg and <0.01-0.22 mg/kg, respectively.
Residues in seeds after a single treatment with BAS 310 55 I at a target rate of 0.025 kg alpha-cypermethrin/ha were below the limit of quantitation (LOQ; 0.01 mg/kg) at all sampling times (13-14, 20-22 and 28-29 DALA).

No residues above the LOQ were found in any of the analysed untreated specimens generated from trials L120460 through L120465.

III. CONCLUSION

After two treatments with BAS 310 55 I at a target rate of 2 x 0.0125 kg alpha-cypermethrin/ha or a single treatment at 0.025 kg alpha-cypermethrin/ha, no residues of alpha-cypermethrin above the limit of quantitation (LOQ, 0.01 mg/kg) were found in seed at 21±1 days or later after the (last) application.

Report: CA 6.3.4/4
Klimmek S.,Gizler A., 2014 c
Study on the residue behaviour of Alpha-Cypermethrin (BAS 310 I) in oilseed rape after two applications with BAS 310 55 I under field conditions in Germany, Belgium, N-France, The Netherlands, S-France, Greece, Italy and Spain, 2013
2013/1416283
Guidelines: none
GLP: yes
(certified by Freie und Hansestadt Hamburg, Behoerde fuer Soziales, Familie, Gesundheit und Verbraucherschutz, Hamburg, Germany)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198: 50 g/L nominal
Purity: not reported
CAS#: 67375-30-8 (alpha-cypermethrin)
Development code: not reported
Spiking levels: 0.01, 0.10 and 8.0 mg/kg

2. Test Commodity:
Crop: Oilseed rape
Type: Oilseeds
Variety: Marquis, DK Esquisite, Safran, msl559c x ccc621205, Anderson, Nelson, Bagira, Frilola
Botanical name: *Brassica napus*
Crop parts(s) or processed commodity: Whole plant w/o roots, rest of plant without roots, pods with seeds, seed
Sample size: Whole plant without roots: ≥ 0.5 kg / 12 units
Rest of plant without roots: ≥ 0.5 kg / 12 units
Pods with seeds: ≥ 0.5 kg
Seed: ≥ 0.5 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2013 growing season, eight field trials were conducted under field conditions in representative oilseed rape growing areas in Germany, Belgium, Northern France, the Netherlands, Southern France, Greece, Italy and Spain to determine the residue level of alpha-cypermethrin (BAS 310 I) in or on Raw Agricultural Commodities (RAC).

Two foliar applications with BAS 310 55 I, an ME formulation of alpha-cypermethrin (50.0 g a.s./L), were made to plot 2 at a rate of 0.25 L of formulated product/ha (equivalent to 0.0125 kg a.s./ha) to oilseed rape at 28 days before harvest (DBH) and at 21 DBH. The nominal spray volume used was 200 L/ha.

Untreated and treated oilseed rape (whole plant (no roots)) specimens were sampled immediately pre application at 0 days before the last application (0 DBLA, GS 75-81) or immediately after the last application (0 DALA, GS 75-81), respectively.
Untreated and treated oilseed rape (seed) specimens were sampled at 14 DALA (GS 88-89), at 21-22 DALA (GS 87-89) and at 27-29 DALA (GS 89-90).
Untreated and treated oilseed rape (rest of plant without roots) specimens were sampled at 13-15 DALA (GS 79-89), at 20-22 DALA (GS 83-89) and at 27-29 DALA (GS 89-90).
Untreated and treated oilseed rape (pods with seeds) specimens were sampled at 13-15 DALA (GS 79-89) and at 20-22 DALA (GS 83-88).

The maximum storage interval from harvest until analysis of alpha-cypermethrin (BAS 310 I) was 439 days.

Table 6.3.4-19: Target application rates and timings for oilseed rape

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2013	8	2	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.0125	200	1st appl. 28, 2nd appl. 21 days before harvest

2. Description of analytical procedures

All oilseed rape specimens were analyzed for alpha-cypermethrin according to BASF analytical method no. 567/0, which determines the analytes by means of LC-MS/MS.
The residues of alpha-cypermethrin in wheat specimens were extracted from plant matrices using a mixture of methanol / water / 2N hydrochloric acid (70:25:5, v/v/v). The extract was centrifuged and an aliquot was partitioned of into cyclohexane. The final determination of alpha-cypermethrin was performed by LC-MS/MS.
As a modification to optimize the recovery of alpha-cypermethrin during the liquid/liquid-partition with cyclohexane, the extract was partitioned three times in order to adapt the method to the laboratory situation.

The limit of quantitation (LOQ) was 0.01 mg/kg for alpha-cypermethrin.

Table 6.3.4-20: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in oilseed rape

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)

	0.1	2			
Overall		**16**	**85.0**	**15.3**	**18.0**

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are given in Table 6.3.4-21, detailed residue levels are shown in Table 6.3.4-22 and Table 6.3.4-23.

At 0 DALA (GS 75-83) the residues of alpha-cypermethrin (BAS 310 I) in oilseed rape (whole plant no roots) specimens ranged between 0.20 mg/kg and 0.31 mg/kg.
At 14 DALA (GS 88-89) the residue of alpha-cypermethrin (BAS 310 I) in oilseed rape (seed) specimen was below the LOQ (<0.01 mg/kg).
At 13-15 DALA (GS 79-89) the residues of alpha-cypermethrin (BAS 310 I) in oilseed rape (rest of plant without roots) specimens ranged between 0.015 mg/kg and 0.15 mg/kg.
At 13-15 DALA (GS 79-89) the residues of alpha-cypermethrin (BAS 310 I) in oilseed rape (pods with seeds) specimens ranged between <0.01 mg/kg and 0.16 mg/kg.
At 21-22 DALA (GS 87-89) the residues of alpha-cypermethrin (BAS 310 I) in the oilseed rape (seed) specimens were all below the LOQ (<0.01 mg/kg).
At 20-22 DALA (GS 83-89) the residues of alpha-cypermethrin (BAS 310 I) in the oilseed rape (rest of plant without roots) specimens ranged between <0.01 mg/kg and 0.13 mg/kg.
At 20-22 DALA (GS 83-89) the residues of alpha-cypermethrin (BAS 310 I) in the oilseed rape (pods with seeds) specimens ranged between 0.036 mg/kg and 0.12 mg/kg.
At 27-29 DALA (GS 89-90) the residues of alpha-cypermethrin (BAS 310 I) in the oilseed rape (seed) specimens ranged between <0.01 mg/kg and 0.015 mg/kg.
At 27-29 DALA (GS 89-90) the residues of alpha-cypermethrin (BAS 310 I) in the oilseed rape (rest of plant without roots) specimens ranged between 0.040 mg/kg and 0.27 mg/kg.
No residues above the LOQ of alpha-cypermethrin (BAS 310 I) were found in any of the untreated specimens.

Table 6.3.4-21: Summary of residues of BAS 310 I in oilseed rape after one or two applications of BAS 310 55 I

III. CONCLUSION

After treatment with BAS 310 55 at a target rate of two applications at 0.0125 kg a.s./ha, alpha-cypermethrin residues in seeds were < 0.01-0.015 mg/kg at 27-29 days after the last application.

Report: CA 6.3.5/1
Tandy R., 2014a
Study on the residue behaviour of Alpha-Cypermethrin (BAS 310 I) in barley after treatment with BAS 310 55 I in Northern and Southern Europe during 2012
2013/1388974
Guidelines: SANCO/3029/99 rev. 4 (11 July 2000), EEC 91/414, EEC 1607/VI/97 rev. 2 10.06.1999
GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198: 50.0 g/L nominal; 101209: 50.0 g/L nominal
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01-1.0 mg/kg

2. Test Commodity:
Crop: Barley
Type: Cereals
Variety: Pelican, Westminster, Naomi, Sebastian, Baracca, Loverde, Arta
Botanical name: *Hordeum vulgare*
Crop parts(s) or processed commodity: Whole plant w/o roots, ears, rest of plant, grain, straw
Sample size: Whole plant without roots: 0 DALA: ≥1.0kg / 12 units
Rest of plant without roots: ≥1.0kg
Grain: ≥1.0kg
Straw: ≥0.5kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the growing season of 2012, a total of seven trials were conducted in representative barley growing areas in Northern Europe (France, Germany, The Netherlands and The United Kingdom) and Southern Europe (France, Greece, Italy) to determine the magnitude and decline of residues of alpha-cypermethrin (BAS 310 I) in or on raw agricultural commodities (RAC).

The trials performed in Northern Europe (France, Germany, The Netherlands and The United Kingdom) consisted of two plots: one untreated plot (control) and one plot treated twice with BAS 310 55 I, a ME formulation of alpha-cypermethrin (50.0 g/L), at a target rate of 0.0125 kg alpha-cypermethrin/ha (plot 2).
In Southern Europe (France, Greece, Italy), the experimental set-up consisted of three plots: one plot untreated, a second plot treated twice with BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha (plot 2) and a third plot treated once with BAS 310 55 I at a target rate of 0.025 kg alpha-cypermethrin/ha (plot 3). Plot 2 was treated 28-36 days before harvest and 21-29 days before harvest, respectively, while plot 3 was treated 21-29 days before harvest. The nominal spray volume used was 200 L/ha. In all trials the applications were made at crop stages BBCH 71-85.
In trial L120445, a higher rate of 0.0153 kg/a.s./ha (+22.3% above target) was applied to plot 2 at the first treatment. In trial L120450, the second application in plot 2 was at a rate of 0.014 kg a.s./ha (+12.22% above target) and the treatment rate for plot 3 was 0.0297 kg a.s./ha (+18.89% above target). These rates are still within 25% that is considered comparable in SANCO 7525/VI/95 - rev.9 and can be regarded as a worst case scenario.

For the analysis samples of barley plant (without roots) were taken directly after the last application (0 DALA). Ears and rest of plant (without roots) or grain and straw were taken at 13-14, 20-21, and 26-29 DALA, depending on the crop maturity.
The maximum storage interval from sampling until analysis was 359 days.

Table 6.3.5-4: Target application rates and timings for barley

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2012	7	2	F	BAS 310 55 I (EC)	alpha-cypermethrin	0.0125	200	1st appl.: 28±1 DBH 2nd appl.: 21±1 DBH
2012	3	1	F	BAS 310 55 I (EC)	alpha-cypermethrin	0.025	200	1st appl.: 21±1 DBH

DBH:days before harvest

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin).
The residues of alpha-cypermethrin in barley specimens were extracted from plant matrices using a mixture of methanol/water/hydrochloric acid (70:25:5, v/v/v). After centrifugation, an aliquot of the extract was partitioned into cyclohexane. An aliquot of the cyclohexane phase was evaporated and the residue was taken up into methanol/water (80:20, v/v). The final determination of alpha-cypermethrin was performed by LC-MS/MS using the ammonium adduct of cypermethrin. The limit of quantitation (LOQ) of the method is 0.01 mg/kg. The mean procedural recovery averaged 81±9% (mean±SD) for alpha-cypermethrin at fortification levels of 0.01 mg/kg -1.0 mg/kg.

Table 6.3.5-5: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in barley

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
whole plant w/o root	0.01-1.0	9	87.4	10.6	12.1
ears	0.01-0.4	6	78.9	7.7	9.8
rest of plant	0.01-0.5	6	82.4	7.2	8.8
grain	0.01-0.2	9	77.9	7.3	9.4
straw	0.01-0.5	6	74.6	5.5	7.3

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.5-6, detailed residue levels are shown in Table 6.3.5-7 and Table 6.3.5-8.
Directly after the last of two applications of BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha, residues of BAS 310 I (alpha-cypermethrin) in whole plant (without root) specimens ranged between 0.27-0.57 mg/kg. At 13-14 days after the last application residues were 0.099-0.33 mg/kg in ears, 0.14-0.45 in rest of plant (without roots) or 0.052 mg/kg and 0.43 mg/kg in grain and straw, respectively. At 20-21 DALA residues were 0.10-0.29 mg/kg in ears, 0.19-0.39 mg/kg in rest of plant without roots or 0.023-0.066 mg/kg and 0.24-0.41 mg/kg in grain and straw, respectively. After a longer PHI (26-29 DALA), residues in ears and rest of plant (without roots) were 0.12 and 0.40 mg/kg, respectively or 0.026-0.053 and 0.21-0.49 mg/kg in grain and straw, respectively.

Directly after a single treatment with BAS 310 55 I at a target rate of 0.025 kg alpha-cypermethrin/ha, residues of BAS 310 I (alpha-cypermethrin) in whole plant (without root) specimens ranged between 0.32-0.61 mg/kg. At 14 days after the last application residues were 0.14-0.23 mg/kg in ears, 0.28-0.35 in rest of plant without roots or 0.099 mg/kg and 0.32 mg/kg in grain and straw, respectively. At 20-21 DALA residues were 0.13-0.21 mg/kg in ears, 0.031-0.39 mg/kg in rest of plant without roots or 0.061 mg/kg and 0.20 mg/kg in grain and straw, respectively. After a longer PHI (26-28 DALA) residues were 0.040-0.043 and 0.29-0.33 mg/kg in grain and straw, respectively.

No residues above LOQ were found in any of the analysed untreated specimens generated from trials L120444 through L120448 and L120450-L120451, respectively.

III. CONCLUSION

The residue levels of BAS 310 I in barley specimens taken directly after the last of two applications at a target rate of 0.0125 kg alpha-cypermethrin/ha (0 DALA) ranged between 0.27-0.57 mg/kg. In cereal grains from the same plots collected at 26-29 DALA, the residues of BAS 310 I were between 0.026-0.053 mg/kg.
Immediately after a single application of 0.025 kg alpha-cypermethrin/ha, the residue levels of BAS 310 I in barley whole plant ranged between 0.32-0.61 mg/kg. In cereal grains from the same plots collected at 26-28 DALA, the residues of BAS 310 I were between 0.040-0.043 mg/kg.

Report:	CA 6.3.5/2 Tandy, R., 2014c Study on the residue behaviour of alpha-cypermethrin (BAS 310 I) in barley after treatment with BAS 310 55 I in Southern Europe during 2013 2013/1416281
Guidelines:	SANCO/3029/99,EEC 1607/VI/97 rev. 2 10.06.1999,EEC 91/414 Annex II (Part A Section 6),EEC 91/414 Annex III (Part A Section 8)
GLP:	yes (certified by ENAC, Entidad Nacional de Acreditación, Madrid Spain)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31055I

Description:	BAS 310 55 I (ME)
Lot/Batch #:	101198: 50 g/L nominal
Purity:	not reported
CAS#:	67375-30-8 (alpha-cypermethrin)
Development code:	not reported
Spiking levels:	0.01, 0.10 and 8.0 mg/kg

2. Test Commodity:

Crop:	Barley
Type:	Cereals
Variety:	Unia
Botanical name:	*Hordeum vulgare*
Crop parts(s) or processed commodity:	Plant w/o roots, rest of plant without roots, ears, grain, straw
Sample size:	Whole plant without roots: ≥ 1 kg / 12 units Rest of plant without roots: ≥ 1 kg Ears: ≥ 1 kg Grain: ≥ 1 kg Straw: ≥ 0.5 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2013 growing season, one field trial was conducted in a representative barley growing area in Spain to determine the residue level of alpha-cypermethrin (BAS 310 I) in or on Raw Agricultural Commodities (RAC).

Plot 2 was treated with BAS 310 55 I, a ME formulation of alpha-cypermethrin (50.0 g/L) and was foliar applied twice at a rate of 0.25 L of formulated product/ha (equal to 0.0125 kg a.s./ha alpha-cypermethrin) to barley 28 days before harvest, and 21 days before harvest. The nominal spray volume used was 200 L/ha.

Plot 3 was treated with BAS 310 55 I, a ME formulation of alpha-cypermethrin (50.0 g/L) and was foliar applied at a rate of 0.5 L of formulated product/ha (equal to 0.025 kg a.s/ha alpha-cypermethrin) to barley 21 days before harvest. The nominal spray volume used was 200 L/ha.
Whole plant specimens were collected immediately before (plot U1) and after (plots 2 and 3) the last application. Ears and rest of plant specimens were collected 14 days after last application (DALA) from the untreated plot (U1) and treated plots 2 and 3. Grain and straw specimens were collected 21 and 28 days after last application (DALA) from the untreated plot (U1) and treated plots 2 and 3.

The maximum storage interval from harvest to first measurement was 296 days for barley specimens.

Table 6.3.5-9: Target application rates and timings for barley

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2013	1	2	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.0125	200	1st appl. 28, 2nd appl. 21 days before harvest

2. Description of analytical procedures

All barley specimens were analyzed for alpha-cypermethrin according to BASF analytical method no. 567/0, which determines the analytes by means of LC-MS/MS.
The residues of alpha-cypermethrin in wheat specimens were extracted from plant matrices using a mixture of methanol / water / 2N hydrochloric acid (70:25:5, v/v/v). After centrifugation and partition of an aliquot of the extract into cyclohexane, evaporation to dryness and dissolving in methanol / water (80+20, v+v), the final determination of alpha-cypermethrin was performed by LC-MS/MS.
The limit of quantitation (LOQ) was 0.01 mg/kg for alpha-cypermethrin.

Table 6.3.5-10: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in barley

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Barley / whole plant no roots	0.01	1	94.7	22	23
	0.1	1			
	8.0	1			
Barley / ears	0.01	1	102.1	14	13
	0.1	1			
	8.0	1			
Barley / rest of plant without roots	0.01	1	82.0	17	20
	0.1	1			
	8.0	1			
Barley / grain	0.01	1	94.7	-	-
	0.10	1			
Barley / straw	0.01	2	94.9	16	17
	0.1	1			
	8.0	1			
Overall		**15**	**93.6**	**16**	**18**

II. RESULTS AND DISCUSSION

The residue results are shown in Table 6.3.5-11 and Table 6.3.5-12.
Residues of alpha-cypermethrin for plot 2 (two treatments at a target rate of 0.0125 kg a.s./ha), 0 days after last application were 0.39 mg/kg for whole plant (no roots) specimens. At 14 days after last application, plot 2, residues of alpha-cypermethrin were 0.38 mg/kg for ears and 0.38 mg/kg for rest of plant (without roots). At 21 days after last application, plot 2, residues of alpha-cypermethrin were 0.067 mg/kg for grain and 0.52 mg/kg for straw specimens. At 28 days after last application, plot 2, residues of alpha-cypermethrin were 0.083 mg/kg for grain and 0.43 mg/kg for straw specimens.

Residues of alpha-cypermethrin for plot 3 (a single treatment at 0.025 kg a.s./ha), 0 days after last application were 0.34 mg/kg for whole plant (no roots) specimens. At 14 days after last application, plot 3, residues of alpha-cypermethrin were 0.42 mg/kg for ears and 0.41 mg/kg for rest of plant (without roots). At 21 days after last application, plot 3, residues of alpha-cypermethrin were 0.12 mg/kg for grain and 0.57 mg/kg for straw specimens. At 28 days after last application, plot 3, residues of alpha-cypermethrin were 0.092 mg/kg for grain and 0.46 mg/kg for straw specimens.
No residues of alpha-cypermethrin at or above the limit of quantitation (0.010 mg/kg) were detected in the untreated barley specimens of this study.

Table 6.3.5-11: Summary of residues of BAS 310 I in barley after application of BAS 310 55 I

					Straw	0.46

1 Days after last application
2 Growth stage at respective sampling

III. CONCLUSION

At 28 days after treatment with BAS 310 55 I at a target rate of either twice 0.0125 kg a.s./ha or once 0.025 kg a.s./ha, the residues of alpha-cypermethrin (BAS 310 I) in barley straw ranged between 0.43 mg/kg and 0.46 mg/kg while in grain residues between 0.083-0.092 mg/kg were detected.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198: 50 g/L nominal
Purity: not reported
CAS#: 67375-30-8 (alpha-cypermethrin)
Development code: not reported
Spiking levels: 0.01-8.0 mg/kg

2. Test Commodity:
Crop: Barley
Type: Cereals
Variety: Semper, Saffron, Malabar, Meridian, Atomo, Meseta, Ketos, Mutso
Botanical name: *Hordeum vulgare*
Crop parts(s) or processed commodity: Whole plant w/o roots, ears, rest of plant, grain, straw
Sample size: Whole plant without roots: ≥1.0 kg / ≥ 12 units
Rest of plant without roots: ≥1.0 kg / ≥ 12 units
Ears: ≥1.0 kg / ≥ 12 units
Grain: ≥1.0 kg / ≥ 12 units
Straw: ≥0.5 kg / ≥ 12 units

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2013 growing season, eight field trials were conducted under field conditions in representative barley growing areas in Germany, Belgium, the United Kingdom, the Netherlands, Italy, Spain, Greece and Southern France to determine the residue level of alpha-cypermethrin (BAS 310 I) in or on Raw Agricultural Commodities (RAC).

Two foliar applications with BAS 310 55 I, an ME formulation of alpha-cypermethrin (50.0 g a.s./L), were made to plot 2 at a rate of 0.25 L of formulated product/ha (equivalent to 0.0125 kg a.s./ha) to barley at 28 days before harvest (28 DBH) and at 21 DBH. The nominal spray volume used was 200 L/ha.

For trial S13-00441-02 (L130027), the actual application rates for plot 2, applications A1 and A2, were more than 25% below the nominal rate due to the incorrect amount of chemical weighed out. The results of this trial are reported separately.

At the day of application, the untreated barley (whole plant (no roots)) specimens were sampled immediately pre application (0 DBLA) and the treated barley (whole plant (no roots)) were taken immediately after the last application (0 DALA).

Untreated and treated barley (ears and rest of plant) specimens were sampled at 13-15 DALA, at 20-21 DALA and at 28 DALA.
Untreated and treated barley (grain and straw) specimens were sampled at 14 DALA, at 20-22 DALA, 27-28 DALA and at 26-36 DALA (BBCH 89, normal commercial harvest).

The maximum storage interval from harvest until analysis was 343 days.

Table 6.3.5-13: Target application rates and timings for barley

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2013	8	2	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.0125	200	1st appl. 28±1, 2nd appl. 21±1 days before harvest

2. Description of analytical procedures

All barley specimens were analyzed for alpha-cypermethrin according to BASF analytical method no. 567/0, which determines the analytes by means of LC-MS/MS.
The residues of alpha-cypermethrin in barley specimens were extracted from plant matrices using a mixture of methanol/water/hydrochloric acid (70:25:5, v/v/v). After centrifugation and partition of an aliquot of the extract into cyclohexane, the final determination of alpha-cypermethrin was performed by LC-MS/MS.
As a modification to optimize the recovery of alpha-cypermethrin during the liquid/liquid-partition with cyclohexane, the extract was partitioned three times in order to adapt the method to the laboratory situation.
The limit of quantitation (LOQ) was 0.01 mg/kg for alpha-cypermethrin.

Table 6.3.5-14: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in barley

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
Whole plant w/o root	0.01, 0.1 and 4.0	3	70.7	13.7	19.4
Ears	0.01 and 0.10	4	76.1	15.4	20.3
Rest of plant without roots	0.01, 0.1 and 8.0	6	79.0	10.1	12.8
Grain	0.01 and 0.10	7	80.2	15.2	19.0
Straw	0.01, 0.1 and 8.0	7	87.2	14.0	16.1
Overall		**27**	**80.1**	**13.7**	**17.1**

II. RESULTS AND DISCUSSION

The residue ranges for the different trials (excluding trial S13-00441-02 / L130027) are shown inTable 6.3.5-15, detailed residue levels are shown in Table 6.3.5-17 and Table 6.3.5-18. The results for trial S13-00441-02 / L130027 are shown in Table 6.3.5-16 and Table 6.3.5-19.

At 0 DALA the residues of alpha-cypermethrin (BAS 310 I) in barley (whole plant (no roots)) specimens ranged between 0.25 mg/kg and 0.78 mg/kg.
Alpha-cypermethrin (BAS 310 I) residues in barley (ears) specimens ranged between 0.048 mg/kg and 0.29 mg/kg at 13-14 DALA and between 0.15 mg/kg and 0.20 mg/kg at 20-21 DALA. At 28 DALA, the alpha-cypermethrin (BAS 310 I) in the barley (ears) specimen was 0.14 mg/kg.
Alpha-cypermethrin (BAS 310 I) residues in barley (rest of plant (without roots)) ranged between 0.16 mg/kg and 0.55 mg/kg at 13-14 DALA and between 0.20 mg/kg and 0.45 mg/kg at 20-21 DALA. At 28 DALA, the alpha-cypermethrin (BAS 310 I) in the barley (rest of plant (without roots)) specimen was 0.38 mg/kg.

Alpha-cypermethrin (BAS 310 I) residues in barley (grain) specimens ranged between 0.024 mg/kg and 0.075 mg/kg at 14 DALA and between 0.027 mg/kg and 0.11 mg/kg at 20-22 DALA.
Alpha-cypermethrin (BAS 310 I) residues in barley (grain) specimens ranged between 0.020 mg/kg and 0.079 mg/kg at 27-28 DALA and between 0.024 mg/kg and 0.079 mg/kg at 26-36 DALA.
Alpha-cypermethrin (BAS 310 I) residues in barley (straw) specimens ranged between 0.37 mg/kg and 0.61 mg/kg at 14 DALA and between 0.37 mg/kg and 0.92 mg/kg at 20-22 DALA. Alpha-cypermethrin (BAS 310 I) residues in barley (straw) specimens ranged between 0.35 mg/kg and 0.68 mg/kg at 27-28 DALA and between 0.40 mg/kg and 0.47 mg/kg at 26-36 DALA.
No residues above the LOQ of alpha-cypermethrin (BAS 310 I) were found in any of the untreated specimens.

Due to application rates being more than 25% below the target rate, the trial S13-00441-02 (L130027) is reported separately.
At 0 DALA the residue of alpha-cypermethrin (BAS 310 I) in the barley (whole plant (no roots)) specimen of trial S13-00441-02 was 0.13 mg/kg.
The alpha-cypermethrin (BAS 310 I) residue in the barley (ears) specimen of trial S13-00441-02 was 0.19 mg/kg at 15 DALA.
The alpha-cypermethrin (BAS 310 I) residue in the barley (rest of plant (without roots)) of trial S13-00441-02 was 0.34 mg/kg at 15 DALA.
The alpha-cypermethrin (BAS 310 I) residue in the barley (grain) specimen of trial S13-00441-02 was 0.026 mg/kg at 18 DALA.
The alpha-cypermethrin (BAS 310 I) residue in the barley (straw) specimen of trial S13-00441-02 was 0.35 mg/kg at 18 DALA.
No residues above the LOQ of alpha-cypermethrin (BAS 310 I) were found in any of the untreated specimens.

Klimmek, S., 2014
Study on the residue behaviour of alpha-cypermethrin (BAS 310 I) in barley after two applications with BAS 310 55 I under field conditions in United Kingdom, 2014
2014/1173599
Guidelines: none
GLP: yes
(certified by Freie und Hansestadt Hamburg, Behoerde für Soziales, Familie, Gesundheit und Verbraucherschutz, Hamburg)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198: 50 g/L nominal
Purity: not reported
CAS#: 67375-30-8 (alpha-cypermethrin)
Development code: not reported
Spiking levels: 0.01-1.0 mg/kg

2. Test Commodity:
Crop: Barley
Type: Cereals
Variety:
Botanical name: *Hordeum vulgare*
Crop parts(s) or processed commodity: Whole plant w/o roots, ears, rest of plant without roots, grain, straw
Sample size: Whole plant without roots: ≥1.0 kg
Rest of plant without roots: ≥1.0 kg / ≥ 12 units
Ears: ≥1.0 kg / ≥ 12 units
Grain: ≥1.0 kg / ≥ 12 units
Straw: ≥0.5 kg / ≥ 12 units

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2014 growing season, one field trial was conducted under field conditions in a representative barley growing area in the United Kingdom to determine the residue level of alpha-cypermethrin (BAS 310 I) in or on Raw Agricultural Commodities (RAC).

Two foliar applications with BAS 310 55 I, an ME formulation of alpha-cypermethrin (50.0 g a.s./L), were made to plot 2 at a rate of 0.25 L of formulated product/ha to barley at 28±1 days before harvest (28±1 DBH) and at 21±1 DBH. The nominal spray volume used was 200 L/ha.

Untreated and treated barley (whole plant (no roots)) specimens were sampled immediately pre application at 0 days before the last application (0 DBLA) or immediately after the last application (0 DALA), respectively.
Untreated and treated barley specimens were sampled at 14±1 DALA, at 21±1 DALA and at 28±1 DALA.

Table 6.3.5-20: Target application rates and timings for barley

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2014	1	2	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.0125	200	1st appl. 28±1, 2nd appl. 21±1 days before harvest

2. Description of analytical procedures

All barley specimens were analyzed for alpha-cypermethrin according to BASF analytical method no. 567/0, which determines the analytes by means of LC-MS/MS.
The residues of alpha-cypermethrin in barley specimens were extracted from plant matrices using a mixture of methanol/water/hydrochloric acid (70:25:5, v/v/v). After centrifugation and partition of an aliquot of the extract into cyclohexane, the final determination of alpha-cypermethrin was performed by LC-MS/MS.
As a modification to optimize the recovery of alpha-cypermethrin during the liquid/liquid-partition with cyclohexane, the extract was partitioned three times in order to adapt the method to the laboratory situation.
The limit of quantitation (LOQ) was 0.01 mg/kg for alpha-cypermethrin.

Table 6.3.5-21: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in barley

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)

	0.1	1			
	1.0	1			
Overall			**73.7**	**10.0**	**13.5**

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.5-22, detailed residue levels are shown in Table 6.3.5-23.

At 0 DALA the residues of alpha-cypermethrin (BAS 310 I) in barley (whole plant (no roots)) specimens were 0.18 mg/kg.
Alpha-cypermethrin (BAS 310 I) residues in barley (ears) specimens were 0.16 mg/kg and in rest of plant without roots 0.21 mg/kg at 14±1 DALA. After 21±1 days, residues in grain were 0.05 mg/kg, while in straw 0.23 mg/kg were detected. After 28 days, residues in grain were 0.03 mg/kg and in straw 0.20 mg/kg, respectively.

Table 6.3.5-22: Summary of residues of BAS 310 I in barley after application of BAS 310 55 I

Region	Year	Application	DALA[1]	Growth stage[2] (BBCH)	Residues Found (mg/kg)	
					Matrix	alpha-cypermethrin (BAS 310 I)
EU-N	2014	BAS 310 55 I (ME) 2 x 0.0125 kg a.s./ha	0		Whole plant no roots	0.18
			14±1		Ears	0.16
			14±1		Rest of plant without roots	0.21

			21±1		Straw	0.23
			28±1		Grain	0.03
			28±1		Straw	0.20

1 Days after last application
2 At harvest

III. CONCLUSION

At 28 days after the last of two applications of BAS 310 55 I, residues of alpha-cypermethrin in barley grain lay at 0.03 mg/kg, while in straw 0.2 mg/kg were found.

The studies not yet evaluated are summarized in the following chapter.

Report:	CA 6.3.6/1 Kreke N.,Gehl J., 2008b Residues of Alpha-Cypermethrin and Acetamiprid in wheat (RAC whole plant, straw and grain) following two treatments with BAS 370 00 I, BAS 310 40 I or BAS 911 10 I from eight open field trials in Northern and Southern Europe in 2007 2008/1002701
Guidelines:	EEC 96/68,EEC 1607/VI/97 rev. 2 10.06.1999,EEC 7029/VI/95 rev. 5,EEC 7525/VI/95 rev. 7,EEC 91/414 Annex II (Part A Section 6),EEC 91/414 Annex III (Part A Section 8)
GLP:	yes (certified by Swiss Federal Office of Public Health, Berne, Switzerland)

Data from supplemental decline trials reported in chapter 6 (supplemental information) indicate that after a more critical application of 1x 15g/ha, residues after 7 days were already <0.01 mg/kg in wheat grains. The last application is therefore more important as the interval between the two applications as residues do not accumulate. Therefore, the applicant considers the results of this study still acceptable even though the interval between two applications is 14 days instead of 7 days.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description:	BAS 370 00 I BAS 310 40 I BAS 9111 0 I
Lot/Batch #:	1463 (BAS 370 00 I, 25 g/L alpha-cypermethrin, 100 g/L acetamiprid, SL) 1209 (BAS 310 40 I, 100 g/L alpha-cypermethrin, EC) FRE-000429 (BAS 9111 0 I, 200 g/kg acetamiprid)

CAS#:	alpha-cypermethrin: 67375-30-8 acetamiprid: 160430-64-8
Development code:	not applicable
Spiking levels:	0.01-1.0 mg/kg (alpha-cypermethrin) 0.01-5.0 mg/kg (acetamiprid)

2. Test Commodity:

Crop:	Wheat
Type:	Cereals
Variety:	Opus, Bussard, Limes, Einstein, Dakter, Eva, Arcancelo, Galera
Botanical name:	*Triticum aestivum*
Crop parts(s) or processed Commodity:	Whole plant w/o root, rest of plant w/o root, straw, grain, ears
Sample size:	0.5-1.0 kg

B. STUDY DESIGN

1. Test procedure

During the 2007 growing season, a total of eight trials were conducted on wheat in order to determine the magnitude of residues of active ingredient(s) in or on Raw Agricultural Commodities (RAC).
Plot 101: Untreated (control)
Plot 102: BAS 370 00 I, a SL formulation of alpha-cypermethrin (25 g/L) and acetamiprid (100 g/L), was applied twice at the rate of 500 mL/ha, in order to determine the magnitude of the residues of active ingredient in or on Raw Agricultural Commodities (RAC).
Plot 103: BAS 310 40 I, an EC formulation of alpha-cypermethrin (100 g/L), was applied twice at the rate of 150 mL/ha, in order to determine the magnitude of the residues of active ingredient in or on Raw Agricultural Commodities (RAC).
Plot 104: BAS 9111 0 I, a WP formulation of acetamiprid (200 g/kg), was applied twice at the rate of 250 g/ha, in order to determine the magnitude of the residues of active ingredient in or on Raw Agricultural Commodities (RAC).
In context of this summary, only the results of alpha-cypermethrin (plot 102 & plot 103) are reported.
Wheat specimens were collected immediately after the last application and 28 ± 1, 35 ± 1 and 42 ± 1 days after the last application.
The maximum storage interval from first sampling until analysis was 321 days.

Table 6.3.6-4: Target application rates and timings for wheat

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2007	8	2	F	BAS 370 00 I (SL)	alpha-cypermethrin acetamiprid	0.0125 0.05	300	49±1 DBH 35±1 DBH
			F	BAS 310 40 I (EC)	alpha-cypermethrin	0.015		
			F	BAS 9111 0 I (WP)	acetamiprid	0.05		

2. Description of analytical procedures

The specimens were analyzed according to BASF analytical method number 567/0 for alpha-cypermethrin and to Nippon Soda CO. LTD method RD-9991 N2 for acetamiprid.
Both methods have a limit of quantification of 0.01 mg/kg in all sample materials. Procedural recoveries averaged 88% for alpha-cypermethrin and 83% for acetamiprid, respectively, at fortification levels between 0.01 and 1 mg/kg (alpha-cypermethrin) or between 0.01 and 5 mg/kg (acetamiprid).
Alpha-cypermethrin: the residues of alpha-cypermethrin are extracted from plant matrices using a mixture of methanol, water and HCl 2 mol/L. For clean-up a liquid/liquid partition against cyclohexane is used. The final determination of alpha-cypermethrin is performed by LC/MS/MS. The limit of quantification (LOQ) ofthe method is 0.01 mg/kg.

Acetamiprid: The residues of acetamiprid are extracted from plant matrices using a mixture of methanol and water. For clean-up a liquid/liquid partition against dichloromethane is used. The final determination of acetamiprid is performed by LC/MS/MS. The limit of quantification (LOQ) ofthe method is 0.01 mg/kg.

Table 6.3.6-5: Summary of recoveries of alpha-cypermethrin and acetamiprid in wheat matrices

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
wheat grain	0.01 / 1.0	20	88	11	13
RD-9991 N2		acetamiprid			
wheat grain, ears, rest of plant w/o roots	0.01 / 0.1 / 5.0	23	83	8	10

II. RESULTS AND DISCUSSION

For alpha-cypermethrin, at all samplings from plot 102 and 103, in wheat grain only residues below or at the LOQ (0.01 mg/kg) were determined. At 0 DALA, in whole plants residues up to 0.82 mg/kg were observed. In straw or rest of plant specimens without roots, sampled at about 28 DALA, residues up to 1.04 mg/kg were determined. In straw specimens sampled at about 35 or 42 DALA, residues up to 0.96 were observed.
An overall summary of the residues is given in Table 6.3.6-6, detailed results are listed in Table 6.3.6-7 and Table 6.3.6-8.

* = without roots

III. CONCLUSION

Directly after the last application of BAS 370 00 I or BAS 310 40 I, the residue of alpha-cypermethrin ranged between 0.18 and 0.82 mg/kg in wheat specimens (whole plants). At 28±1 days (and later) the residues found in grain ranged between <0.01 and 0.01 mg/kg.
The analytical results obtained demonstrate that the treatment with two applications of either BAS 370 00 I or BAS 310 40 I did not lead to significantly different residue results in the raw agricultural commodity at harvest.

Report: CA 6.3.6/2
Tandy R., 2014d
Study on the residue behaviour of Alpha-Cypermethrin (BAS 310 I) in wheat after treatment with BAS 310 55 I in Northern and Southern Europe during 2012
2014/1028112

Guidelines: SANCO/3029/99 rev. 4 (11 July 2000), EEC 7029/VI/95 rev. 5, EEC 91/414, EU Regulation 1107/2009 with Regulation 283/2013, EU Regulation 1107/2009 with Regulation 284/2013

GLP: yes
(certified by Department of Health of the Government of the United Kingdom, United Kingdom)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198: 50.0 g/L nominal
Purity: not reported
CAS#: 67375-30-8
Development code: not reported
Spiking levels: 0.01-1.5 mg/kg

2. Test Commodity:
Crop: Wheat
Type: Cereals
Variety: Tabasco, AC Barrie, Granary, Gabriel, Imgeuio, Simeto, Dylan, Bastide
Botanical name: *Triticum aestivum*
Crop parts(s) or processed commodity: Whole plant w/o root, rest of plant, straw, grain, ears
Sample size: Whole plant w/o root ≥1.0 kg / 12 units; ears, rest of plant (w/o roots), grain ≥1.0 kg; straw ≥0.5 kg

B. STUDY DESIGN AND METHODS

1. Test procedure

During the growing season of 2012, a total of eight trials were conducted in representative wheat growing areas in Northern and Southern Europe to determine the magnitude and decline of residues of alpha-cypermethrin (BAS 310 I) in or on raw agricultural commodities (RAC).

The trials performed in Northern Europe (France, Germany, and The United Kingdom-2 trials) consisted of two plots: one untreated plot (control) and one plot treated twice with BAS 310 55 I (ME, 50 g a.s./L) at a target rate of 0.0125 kg alpha-cypermethrin/ha.

In Southern Europe (France, Greece, Italy and Spain), the experimental set-up consisted of three plots: one plot untreated, a second plot treated twice with BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha and a third plot treated once with BAS 310 55 I at a target rate of 0.025 kg alpha-cypermethrin/ha.
The applications to plot 2 (two applications at 0.0125 kg alpha-cypermethrin/ha) were made 35 - 72 days before harvest, and 28 - 65 days before harvest. Plot 3 (single application at 0.025 kg alpha-cypermethrin/ha) was treated 28 - 36 days before harvest. The nominal spray volume used was 200 L/ha for both variants.
For the analysis samples of wheat plant (without roots) were taken directly after the last application (0 DALA). Ears and rest of plant (without roots) or grain and straw were taken at 13-15, 20-22, 28-29 and 35-65 DALA, depending on the crop maturity.
The maximum storage interval from sampling until analysis was 393 days.

Table 6.3.6-9: Target application rates and timings for wheat

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2012	8	2	F	BAS 310 55 I (EC)	alpha-cypermethrin	0.0125	200	1st appl.: 28±1 DBH 2nd appl.: 21±1 DBH
2012	4	1	F	BAS 310 55 I (EC)	alpha-cypermethrin	0.025	200	1st appl.: 21±1 DBH

DBH: days before harvest

2. Description of analytical procedures

The method BASF No. 567/0 was used in this study for the determination of BAS 310 I (alpha-cypermethrin).
The residues of alpha-cypermethrin in wheat specimens were extracted from plant matrices using a mixture of methanol/water/hydrochloric acid (70:25:5, v/v/v). After centrifugation, an aliquot of the extract was partitioned into cyclohexane. An aliquot of the cyclohexane phase was evaporated and the residue was taken up into methanol/water (80:20, v/v). The final determination of alpha-cypermethrin was performed by LC-MS/MS using the ammonium adduct of cypermethrin. The limit of quantitation (LOQ) of the method is 0.01 mg/kg. The mean procedural recovery averaged 80.9±10.8% (mean±SD) for alpha-cypermethrin at fortification levels of 0.01 mg/kg -1.5 mg/kg.

Table 6.3.6-10: Summary of recoveries of BAS 310 I (alpha-cypermethrin) in wheat

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
whole plant w/o root	0.01-1.0	6	91.7	4.0	4.4
ears	0.01-0.6	9	79.1	6.3	8.0
rest of plant (without roots)	0.01-0.5	6	72.6	4.4	6.1
grain	0.01-0.5	11	78.4	9.3	11.9
straw	0.01-1.5	9	84.3	15.6	18.6

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.6-11, detailed residue levels are shown in Table 6.3.6-12 and Table 6.3.6-13.
Directly after the last of two applications of BAS 310 55 I at a target rate of 0.0125 kg alpha-cypermethrin/ha, residues of BAS 310 I (alpha-cypermethrin) in whole plant (without root) specimens ranged between 0.17-0.86 mg/kg. At 13-15 days after the last application residues were 0.088-0.40 mg/kg in ears, 0.11-0.44 in rest of plant (without roots) or <0.01 mg/kg and 0.346 mg/kg in grain and straw, respectively. At 20-22 DALA, residues were 0.069-0.41 mg/kg in ears, 0.13-0.38 mg/kg in rest of plant (without roots) or <0.01-0.013 mg/kg and 0.26-0.71 mg/kg in grain and straw, respectively. At 28-29 DALA, residues in ears and rest of plant (without roots) were 0.047-0.24 and 0.11-0.33 mg/kg, respectively or <0.01 and 0.29-0.53 mg/kg in grain and straw, respectively. After a longer PHI (35-65 DALA), residues were <0.01 mg/kg in grain and 0.18-0.35 in straw.
Directly after a single treatment with BAS 310 55 I at a target rate of 0.025 kg alpha-cypermethrin/ha, residues of BAS 310 I (alpha-cypermethrin) in whole plant (without root) specimens ranged between 0.44-0.89 mg/kg. At 14 days after application, residues were 0.098-0.32 mg/kg in ears, 0.12-0.27 in rest of plant (without roots) or <0.01 mg/kg and 0.45 mg/kg in grain and straw respectively. At 21-22 DALA residues were 0.11-0.27 mg/kg in ears, 0.11-0.32 mg/kg in rest of plant (without roots) or <0.01 mg/kg and 0.46-0.84 mg/kg in grain and straw, respectively. At 28 DALA, residues in ears and rest of plant (without roots) were 0.064-0.21 and 0.12-0.19 mg/kg, respectively or <0.01 and 0.36-0.74 mg/kg in grain and straw, respectively.After a longer PHI (36 DALA), residues were <0.01 and 0.26 mg/kg in grain and straw, respectively.

No residues above the LOQ were found in any of the analysed untreated specimens generated from trials L120452 through L120459.

III. CONCLUSION

The residue levels of BAS 310 I in wheat specimens taken directly after the last of two applications at a target rate of 0.0125 kg alpha-cypermethrin/ha (0 DALA) ranged between 0.17-0.86 mg/kg. In wheat grains from the same plots collected at 28±1 DALA and later, no residues above the LOQ were detected (<0.01 mg/kg).
Immediately after a single application of 0.025 kg alpha-cypermethrin/ha, the residue levels of BAS 310 I in wheat whole plant (without roots) ranged between 0.44-0.89 mg/kg. In wheat grains from the same plots collected at 28±1 DALA and later, no residues above the LOQ were detected (<0.01 mg/kg).

Report: CA 6.3.6/3
Klimmek, S., Gizler, A., 2014d
Study on the residue behaviour of alpha-cypermethrin (BAS 310 I) in wheat after two applications with BAS 310 55 I under field conditions in Germany, Northern France, Italy and Spain, 2013
2013/1416282
Guidelines: none
GLP: yes
(certified by Freie und Hansestadt Hamburg, Behoerde für Soziales, Familie, Gesundheit und Verbraucherschutz, Hamburg)

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material: Alpha-Cypermethrin BAS 31055I
Description: BAS 310 55 I (ME)
Lot/Batch #: 101198: 50 g/L nominal
Purity: not reported
CAS#: 67375-30-8 (alpha-cypermethrin)
Development code: not reported
Spiking levels: 0.01, 0.1 and 8.0 mg/kg

2. Test Commodity:
Crop: Wheat
Type: Cereals
Variety: Tabasco, Courtot, Blasco, Burgos
Botanical name: *Triticum aestivum*
Crop parts(s) or processed commodity: Plant w/o roots, rest of plant without roots, ears, grain, straw
Sample size: Plant without roots: 0 DALA ≥ 1 kg / ≥ 12 units
14±1, 21±1, 28±1 DALA:
Rest of plant without roots: ≥ 1 kg / ≥ 12 units
Ears: ≥ 1 kg / ≥ 12 units
Grain: ≥ 1 kg / ≥ 12 units
Straw: ≥ 0.5 kg / ≥ 12 units

B. STUDY DESIGN AND METHODS

1. Test procedure

During the 2013 growing season, four field trials were conducted under field conditions in representative wheat growing areas in Germany, Northern France, Italy and Spain to determine the residue level of alpha-cypermethrin (BAS 310 I) in or on Raw Agricultural Commodities (RAC).
Two foliar applications with BAS 310 55 I, an ME formulation of alpha-cypermethrin (50.0 g a.s./L), were made to plot 2 to wheat, at a rate of 0.25 L formulated product/ha, equal to 12.5 g alpha-cypermethrin/ha. The nominal spray volume used was 200 L/ha.
Untreated and treated wheat specimens of all trials were sampled immediately pre application at 0 days before the last application (0 DBLA, untreated whole plant no roots specimens only), at 0 days after the last application (0 DALA, treated whole plant no roots specimens only) and at 14 (ears and rest of plant or grain and straw, according to the stage of the crop), 20-21 (ears and rest of plant or grain and straw, according to the stage of the crop) and 27-28 (grain and straw) days after the last application.

The maximum storage interval from harvest until analysis was 372 days.

Table 6.3.6-14: Target application rates and timings for wheat

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2013	4	2	F	BAS 310 55 I (ME)	alpha-cypermethrin	0.0125	200	1st appl. 28±1, 2nd appl. 21±1 days before harvest

2. Description of analytical procedures

All wheat specimens were analyzed for alpha-cypermethrin according to BASF analytical method no. 567/0, which determines the analytes by means of LC-MS/MS.
The residues of alpha-cypermethrin in wheat specimens were extracted from plant matrices using a mixture of methanol / water / 2N hydrochloric acid (70:25:5, v/v/v). After centrifugation and partition of an aliquot of the extract into cyclohexane, evaporation to dryness and dissolving in methanol / water (80+20, v+v), the final determination of alpha-cypermethrin was performed by LC-MS/MS.
As a modification to optimize the recovery of alpha-cypermethrin during the liquid/liquid-partition with cyclohexane, the extract was partitioned three times in order to adapt the method to the laboratory situation.
The limit of quantitation (LOQ) was 0.01 mg/kg for alpha-cypermethrin.

II. RESULTS AND DISCUSSION

The residue ranges for the different trials are shown in Table 6.3.6-16. Detailed results are shown in Table 6.3.6-17 and Table 6.3.6-18.

At 0 DALA the residues of alpha-cypermethrin (BAS 310 I) in wheat (whole plant no roots) specimens ranged between 0.35 mg/kg and 0.56 mg/kg. At 14 days after the last application, residues in wheat (ears) specimens ranged between 0.026 mg/kg and 0.095 mg/kg and between 0.25 mg/kg and 0.40 mg/kg wheat (rest of plant without roots) specimens. At the same sampling point, the residue of alpha-cypermethrin (BAS 310 I) in the wheat (grain) specimen was below the LOQ (<0.01 mg/kg), while a residue of 0.32 mg/kg was determined in straw. After 20 days, the residue of alpha-cypermethrin (BAS 310 I) in the wheat (ears) specimen was 0.082 mg/kg and 0.23 mg/kg in the wheat (rest of plant no roots) specimen. Residues in wheat (straw) specimens ranged between 0.32 mg/kg and 0.38 mg/kg at 21 days after the last application. In wheat (grain) specimens the residues were all below the LOQ (<0.01 mg/kg) at 21 days after the last application. At harvest (27-28 DALA, GS 89) the residues of alpha-cypermethrin (BAS 310 I) in wheat (grain) specimens were all below the LOQ (<0.01 mg/kg), while the residues of alpha-cypermethrin (BAS 310 I) in wheat (straw) specimens ranged between 0.36 mg/kg and 0.47 mg/kg.
No residues of alpha-cypermethrin (BAS 310 I) above the LOQ were found in the untreated specimens of this study, with the exception of rest of plant without roots specimen L1300360003 of trial S13-00445-03 (L130036), taken at 14 DALA (GS 87), where an alpha-cypermethrin (BAS 310 I) residue of 0.019 mg/kg was detected. The source of the contamination has not been determined. Taking into account the corresponding residues in the treated specimens the residue in the control sample had no impact on the study.

Table 6.3.6-16: Summary of residues of BAS 310 I in wheat after application of BAS 310 55 I

Region	Year	Application	DALA[1]	Growth stage[2] BBCH	Residues Found (mg/kg)

III. CONCLUSION

At 27-28 days after the last of two applications of BAS 310 55I at a target rater of 0.0125 kg a.s./ha, the residues of alpha-cypermethrin (BAS 310 I) in straw ranged between 0.36 mg/kg and 0.47 mg/kg. No residues above the LOQ were detected in any grain samples at the PHI or at earlier time points (all <0.01 mg/kg).

DALA = Days after last application
BBCH = Growth stage (GS) at respective sampling
* = without roots
_ underlined values were used for MRL calculation

In addition to the studies presented in CA 6.3 for the representative crops cereals, oil seed rape, lettuce, courgette and leafy cabbage, supervised field trials on other crops for which registrations of alpha-cypermethrin based products exist are presented in a supplement document (DocID 2014/1314800). These studies were conducted at the currently registered GAP for the respective crops and are presented to provide additional information on the derivation of crop related MRLs and STMRs used in the chronic dietary risk assessment presented in section CA 6.7 of this dossier and for the determination of metabolite relevance. These calculations are presented in detail in the supplement document and the results are summarized in section CA 6.9. The additional studies are partly peer reviewed, but also new studies are presented. These data are not meant to be fully evaluated but to provide further information as outline above.

CA 6.4 Feeding studies

Intended uses with the representative formulation BAS 310 55 I covered in this submission include kale, oilseed rape and cereals which are relevant feed items.
As a chronic consumer risk assessment based on only these crops does not allow a realistic overall assessment a second scenario was calculated comprising all uses intended to be defended in future. Feeding studies necessary as basis for these calculations were all submitted during the peer review under Directive 91/414/EEC. No new studies were conducted.

CA 6.4.1 Poultry

During the peer review under Directive 91/414/EEC, a feeding study with laying hens (AL-440-018) was submitted. This study was assessed as not being required as the feed burden estimate performed resulted in a maximum intake of 0.085 mg/kg diet which was below the trigger (3rd Addendum to the Monograph: Addendum Chapter B-7 (Residue data), January 2003). Therefore, a review was not performed at this time. This study was not included in the application as it had been submitted already with the alpha-cypermethrin addendum dossier.

Report:	CA 6.4.1/1 [redacted] 2001a Fastac insecticide (Alphacypermethrin - BAS 310 I): Magnitude of BAS 310 I residues in laying hen eggs, muscle, liver and abdominal fat after oral administration of BAS 310 I for 28 consecutive days AL-440-018
Guidelines:	EPA 860.1480, EEC 91/414, EEC 7031/VI/95 Appendix G rev. 4, SANCO/3029/99 rev. 4 (11 July 2000), 8046/VI/97-rev 4 (15/12/1998)
GLP:	yes (certified by <none>)

Executive Summary

The objective of the present study was to investigate the magnitude of alpha-cypermethrin residues in poultry tissues and eggs. In this study, 56 acclimated laying hens were divided randomly into 6 treatment groups: placebo (A, 12 hens), 1.2 mg/kg feed (B, 12 hens), 6.1 mg/kg feed (C, 12 hens) and 12 mg/kg feed (D, 12 hens / E, 4 hens / F, 4 hens). The nominal doses were equivalent to approximately 0.076, 0.38 and 0.76 mg a.s./kg bw/animal/day. Each hen/group was orally dosed once daily for 28 consecutive days using gelatin capsules. Alpha-cypermethrin accumulation was monitored in composite egg and edible tissue samples (muscle, liver and abdominal fat) from each treatment group. Egg samples were collected approximately 3 times each week during the dosing period, and edible tissues were collected immediately upon sacrifice. Group A-D animals were sacrificed within 24 hours of receiving their final (28th) dose. Group E and F animals were sacrificed at 7 days after the final dose and at 14 days after the final dose, respectively.

No residues of alpha-cypermethrin above the LOQ (0.01 mg/kg) were detected in eggs from treated hens in the 1.2 mg/kg group. In the 6.1 mg/kg dose group, residues slightly above the LOQ from day 9 until the end of the dosing period (0.0101-0.0125 mg/kg between day 9-28).
Alpha-cypermethrin residues in eggs from treated hens in the high dose group reached a plateau averaging approximately 27 mg/kg within approximately 21-24 days of dosing. There were no reportable residues after 7 days' depuration.
Alpha-cypermethrin residues did not accumulate in laying hen liver or muscle after 28 daily doses. Residues were <0.05 mg/kg in liver and muscle tissue sampled from the high dose animals. Alpha-cypermethrin residues in laying hen abdominal fat averaged approximately 0.235 mg/kg after 28 days of dosing at the high rate and 0.085 mg/kg at the medium rate. No residues above the LOQ (0.05 mg/kg) were detected in fat tissue from the low dose group. A residue decline in abdominal fat of approximately 61% was noted in the high dose group after 7-14 days' depuration.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: Alpha-cypermethrin (BAS 310 I, former code AC 900049)
Lot/Batch #: AC12395-18
Purity: 96.1 %
CAS#: 67375-30-8
Development code: not reported
Dose levels: equivalent to 0 (placebo) / 1.21 / 6.05 / 12.1 mg/kg in feed (nominal)
Spiking levels: 0.01-0.5

2. Test Commodity:

Organism: Poultry
Type: Chicken
Variety: Babcock B-300 White Leghorn (Hens)
Systematical name: *Gallus gallus domesticus*
commodity: Eggs, muscle, abdominal fat, liver
Sample size: Eggs: Eggs were collected twice per sampling interval. Each egg sampling interval consisted of all eggs from the PM collection of the day previous plus all eggs from the AM collection of that sampling day. All eggs from the four hens per treatment subgroup were collected at each sampling timepoint.
Sacrifice within 24 h after final dosing:

Muscle:	332-539 g (composite samples, 4 animals)
Abdominal fat:	83-156 g (composite samples, 4 animals)
Liver:	112-153 g (composite samples, 4 animals)

B. STUDY DESIGN

1. Test procedure

Fifty-six acclimated laying hens were divided randomly into 6 treatment groups: placebo (A, 12 hens), 1.2 mg/kg feed (B, 12 hens), 6.1 mg/kg feed (C, 12 hens) and 12 mg/kg feed (D, 12 hens / E, 4 hens / F, 4 hens). The nominal doses were equivalent to approximately 0.076, 0.38 and 0.76 mg a.s./kg bw/animal/day.
Each hen/group was orally dosed once daily for 28 consecutive days using gelatin capsules. The test material was a Certified Toxicological sample at 96.1 % purity.

Lock ring gelatin capsules (Torpac, size 0, batch 1610892, expiration October 2003) filled with were used. The lactose was delivered into capsules using a capsule-filling machine.
Test substance dosing solutions were prepared in 1: 5 acetone: n-hexane, such that every capsule would receive the same volume of working solution independent of the dose rate. Each capsule received 100 µl of the appropriate dosing solution. Solvent was permitted to evaporate from the capsules at room temperature for at least 3 hours prior to packaging. Each dosing capsule was placed into a labeled vial, packaged together according to dose group in appropriately labeled boxes, and stored refrigerated until use in the study.

BAS 310 I accumulation was monitored in composite egg and edible tissue samples (muscle, liver and abdominal fat) from each treatment group. Egg samples were collected approximately 3 times each week during the dosing period. Eggs were collected twice per sampling interval. Each egg sampling interval consisted of all eggs from the PM collection of the day previous plus all eggs from the AM collection of that sampling day. All eggs from the four hens per treatment subgroup were collected at each sampling timepoint.
Edible tissues were collected immediately upon sacrifice. Group A-D animals were sacrificed within 24 hours of receiving their final (28th) dose. Group E and F animals were sacrificed at 7 days after the final dose and at 14 days after the final dose, respectively.

All samples from each sampling interval were hand-delivered to the Sample Preparation and Handling Area (SPHA) at BASF in Princeton, NJ. Egg samples were homogenized within 2 hours of receipt. The resulting homogenate was divided into three 50-ml polypropylene conical tubes and were placed into a freezer at approximately ≤-10°C, where they were maintained until transfer into analytical laboratory custody.

Edible tissue samples were logg placed into a freezer maintained at approximately ≤-10°C until preparation for analysis. During preparation, individual tissue samples were thoroughly ground and homogenized in a Hobart food chopper surrounded by dry ice. The resulting homogenates were divided into two sub-samples, packed into cardboard containers, and were placed back into the freezer until transfer to the analytical laboratory.

Egg sub-samples were removed from SPHA storage and transferred to the analytical laboratory for processing. Edible tissue sub-samples were shipped by Federal Express to the contract analytical laboratory (MAXIM Technologies, Incorporated in Middleport, NY).

Statistics:
Other than calculation of means, standard deviations and CVs, no statistical analysis was performed on the data from this study. This study was properly controlled throughout its in-life and analytical phases to minimize bias.

2. Description of analytical procedures

Remark: Although analytical method SAMS 461-1 has already been assessed, it is briefly described for completeness of the study summary.

BASF method SAMS 461-1 for hen tissues:
Edible tissues were collected and analyzed for ~~BAS 310 I~~total cypermethrin residues according to BASF method SAMS 461-1, which was validated for hen muscle, liver and abdominal fat as part of this study (LOQ, 0.05 mg/kg). Method SAMS 461-1 was peer-reviewed under Directive 91/414/EEC earlier (Alpha-cypermethrin Monograph, 1999).

Principle of method SAMS 461-1:
Residues of BAS 310 I were extracted from poultry tissues by boiling (three times) with acetone:hexane (1 :2; v/v). The extract was concentrated to dryness and redissolved in hexane. For fat and meat an aliquot of the extract is partitioned with acetonitrile using an Extrelut cartridge. For liver, an aliquot was removed and a liquid/liquid, hexane/acetonitrile partition was used. The extract was further cleaned up by SPE using a Florisil cartridge. Residues were quantitated using a GC equipped with an ECD. Results were calculated by the direct comparison of peak heights to those of external standards. The validated sensitivity (LOQ, limit of quantitation) of the method is 0.05 mg/kg.

Table 6.4.1-1: Summary of Validation data of alpha-cypermethrin in hen´s tissues

Matrix Poultry	Fortification Level (mg/kg)	Summary Recoveries				
		Individual recoveries (%)	n	Mean (%)	SD	RSD (%)

	0.50	100 / 98 / 108 / 93 / 93	5	98	6.2	6.3

Table 6.4.1-2: Method SAMS 461-1 - Concurrent recoveries

Compound	Matrix Poultry	Range		
		Fortification Level (mg/kg)	Recovery (%)	Average recovery (%)
BAS 310 I	Meat	0.05	115	NA
	Liver	0.05-0.50	78-88	83 (n=2)
	Fat	0.05-0.50	86-107	93 (n=3)

BASF method M 3466 for hen eggs:
Egg samples were analyzed for BAS 310 I residues according to BASF method M 3466 (limit of quantitation, LOQ, 0.01 mg/kg) which was validated in this study. Method M 3466 as a part of this poultry-feeding study was not peer-reviewed under Directive 91/414/EEC earlier because the whole study was regarded as not required due to an anticipated feed burden below the trigger value. Therefore, the validation results and method performance parameters are summarized in detail below.

Principle of the method M 3466:
In the validated method, residues of BAS 310 I are extracted from homogenized eggs with a mixture of hexane and tetrahydrofuran (THF) (1:2 v/v). Aliquots of the organic extracts are evaporated and the residue is dissolved in a mixture of hexane and dichloromethane (1:1 v/v). Extracts are purified using adsorption chromatography on a one-gram silica SPE cartridge, followed by liquid-liquid partitioning using hexane/acetonitrile. Quantitative determination is carried out by gas chromatography/electron capture negative ion chemical ionization tandem mass spectrometry (GC/MS-ECNICI). Results are calculated as BAS 310 I by the direct comparison of the sample peak response to the peak responses of bracketing standards. The validated sensitivity (LOQ, limit of quantitation) of the method is 0.01 mg/kg.

Detailed results of the method validation are given in Table 6.4.1-1. Concurrent recoveries from egg sample analysis, extract and freezer stability analyses are presented in Table 6.4.1-2.

Table 6.4.1-3: Method M 3466 - Summary of method accuracy and precision (method validation)

Commodity	Fortification level (mg/kg)	Recovery (%)	Recovery range (%)	Mean recovery (%)	SD (%)	RSD (%)
Hen egg	0.01	119 / 102 / 117 / 106 / 106	102-119	110	8	7
	0.1	96 / 97 / 95 / 74 / 98	74-98	92	10	11
Overall (n=10)			**74-119**	**101**	**13**	**13**

Table 6.4.1-4: Method M 3466 - Concurrent recoveries from egg sample analysis, extract and freezer stability analyses

Fortification level (mg/kg)	Recovery range (%)	Mean recovery (%)
0.01	71-119	101 (n=15)
0.1	83-116	97 (n=15)
Overall	**71-119**	**99 (n=30)**

Recovery findings:
The method was validated at two fortification levels (0.01 and 0.1 mg/kg) in hen eggs. For each fortification level, five replicates were analyzed. Additionally, two replicates of unfortified samples were examined. It was proven that the method M 3466 is suitable to determine residues of BAS 310 I in hen eggs´samples. As shown in Table 6.4.1-1, the mean recovery values were found to be within the acceptable range of 70-120% for all methods tested. The overall relative standard deviations (RSD, %) for all fortification levels were below 20%.

Linearity:
Good linearity was demontrated with r=0.9997.

Specificity:
Specificity was demonstrated by the absence of interferences in the control samples.

Limit of Quantitation:
The limit of quantitation (LOQ) was defined by the lowest fortification level successfully tested. LOQ is 0.01 mg/kg for BAS 310 I.

Repeatability:
The overall relative standard deviations (RSD, %) for all fortification levels were below 20%. The detailed values are shown in Table 6.4.1-1.

Reproducibility:
Reproducibility of the method was not determined within this validation study.

II. RESULTS AND DISCUSSION

Observation:
Actual BAS 310 I doses to the hens in this study averaged approximately 100, 132, 119, 124, 140, and 149 percent of the intended daily rates/hen in treatment Groups A-F, respectively. There were no significant differences observed in average animal weights, egg production (total egg weights or numbers), feed intake or general health across treatment groups during the in-life phase. There were no treatment-related side effects noted. A summary is shown in Table 6.4.1-1.

Table 6.4.1-5: Actual Average Daily BAS 310 I Doses/Hen

Group	No. of animals	Average hen weight per group (kg)[b, d]	µg a.s. /hen/day[a]	Average daily feed intake /hen (g dry matter)	Average mg a.s./kg bw/day[b, d]	Average mg/kg BAS 310 I in daily diet (µg a.s. per gram dry feed/day)[c, d, e]
A	12	1.54	0	101	0	0
B	12	1.53	151	94	0.0987	1.6
C	12	1.61	757	105	0.470	7.2
D	12	1.56	1506	99	0.965	15
E	4	1.58	1506	90	0.953	17
F	4	1.41	1506	86	1.07	18

Small discrepancies in dose estimates due to significant figures.

a Based on nominal values as calculated by the analyst who prepared working capsule dosing solutions. Values are adjusted for 96.1% potency of the test substance. Not adjusted for dose verification assay results.

b Based upon the average of pre-treatment and at sacrifice weights across the entire treatment group.

c Based on average daily feed consumption (adjusted for 90% feed dry matter) across the 28 day treatment period of 112, 104, 117, 110, 100 and 95 grams dry matter/hen/day for groups A-F respectively.

d There were no significant differences noted across treatment groups for average total egg production/hen, average total egg weight/hen, average dry matter consumption/hen or average general heath/hen during the course of this study. Average and standard deviation of pre-treatment and at sacrifice hen weights across all treatment groups was approximately 1.54 ± 0.07 kg.

e Actual average daily doses administered to study AP00PT06 were 100, 132, 119, 124, 140, and 149 percent of intended on a ppm (mg/kg feed) basis.

No residues of alpha-cypermethrin above the LOQ (0.01 mg/kg) were detected in eggs from treated hens in the 1.2 mg/kg group. In the 6.1 mg/kg dose group, residues slightly above the LOQ were found from day 9 until the end of the dosing period (0.0101-0.0125 mg/kg between day 9-28). BAS 310 I residues in eggs from treated hens in the high dose group reached a plateau averaging approximately 0.027 mg/kg within approximately 21-24 days of dosing. There were no reportable residues after 7 days' depuration. Apparent BAS 310 I residues in eggs from untreated animals were <0.002 mg/kg.
A summary of egg results is shown in Table 6.4.1-2.

Notes:
Dosing was stopped on day 28. Sample 4112 and 5112 were collected on day 35 and 42, respectively.

Protocol section 11.4 directed the analyst to analyze egg samples from the highest treatment group first. If there were no quantifiable residues, samples from lower treatment groups did not need to be analyzed. Blanks indicate egg samples not analyzed. Refer to protocol deviation #4 regarding samples 1131, 1132 and 1133

BAS 310 I residues did not accumulate in laying hen liver or muscle after 28 daily doses. Residues were <0.05 mg/kg in liver and muscle tissue sampled from the high dose animals. BAS 310 I residues in laying hen abdominal fat averaged approximately 0.235 mg/kg after 28 days of dosing at the high rate and 0.085 mg/kg at the medium rate. No residues above the LOQ (0.05 mg/kg) were detected in fat tissue from the low dose group. A residue decline in abdominal fat of approximately 61% was noted in the high dose group after 7-14 days' depuration. BAS 3101 was stable in refrigerated muscle, liver and abdominal fat extracts for at least 7, 8 and 5 days, respectively. There was no need to collect storage stability data in laying hen tissues, since samples were analyzed within 30 days of collection. Apparent BAS 310 I residues in edible tissues from untreated animals were <0.01 mg/kg.
A summary of edible tissue results is shown in Table 6.4.1-3.

Table 6.4.1-7: Summary of BAS 310 I Residues Found in Edible Tissues in Study AP00PT06

Extract stability:
Final extracts from method validation were used for extract stability study. BAS 310 I was stable in egg extracts for at least 7 days.
The results are summarized in Table 6.4.1-1.

Table 6.4.1-8: Summary of Stability of BAS 310 I Residues in Extract of Hen Egg:

	Fortification Level (mg/kg)	Recovery (%)					Mean Recovery (%)	SD (%)	RSD (%)
fresh extract	0.01	119	102	117	106	106	110	8	7
extract stored for 7 days	0.01	123	100	112	105	110	110	9	8

III. CONCLUSION

No residues of alpha-cypermethrin above the LOQ (0.01 mg/kg) were detected in eggs from treated hens in the 1.2 mg/kg group. In the 6.1 mg/kg dose group, residues slightly above the LOQ were found from day 9 until the end of the dosing period (0.0101-0.0125 mg/kg between day 9-28).
Alpha-cypermethrin residues in eggs from treated hens in the high dose group reached a plateau averaging approximately 27 mg/kg within approximately 21-24 days of dosing. There were no reportable residues after 7 days' depuration.
Alpha-cypermethrin residues did not accumulate in laying hen liver or muscle after 28 daily doses. Residues were <0.05 mg/kg in liver and muscle tissue sampled from the high dose animals. Alpha-cypermethrin residues in laying hen abdominal fat averaged approximately 0.235 mg/kg after 28 days of dosing at the high rate and 0.085 mg/kg at the medium rate. No residues above the LOQ (0.05 mg/kg) were detected in fat tissue from the low dose group. A residue decline in abdominal fat of approximately 61% was noted in the high dose group after 7-14 days' depuration.

CA 6.4.2 Ruminants

During the peer review under Directive 91/414/EEC, four studies on the magnitude of alpha-cypermethrin residues in ruminants were submitted. Three of these studies (Al-870-020, Al-870-021 and Al-870-022) were related to a dermal exposure and were assessed as being out of interest.

One feeding study with lactating cows (AL-705-006) was peer-reviewed. In this study, 3 groups of 3 dairy cows were fed with oral doses of alpha-cypermethrin incorporated in capsules for 28 days at dosages of 77, 231 and 769 mg alphacypermethrin/cow/day (corresponding to about 3.9, 11.6 and 38.5 mg/kg in diet/day). Milk samples were collected for determination of alpha-cypermethrin residues on study days –1, 1, 2, 3, 6, 8, 10, 13, 15, 17, 20, 22, 24, and 27. Animals were sacrificed within 24 hours after the final dose. Cattle muscle, liver, kidney, and fat samples were taken for alpha-cypermethrin analysis.

At the lowest feeding level, residues of alphacypermethrin were present only in fat (0.058-0.064 mg/kg). All samples of whole milk from the 1 x dose rate group were below the limit of determination of the analytical method (0.010 mg/kg) for alpha-cypermethrin.

Alpha-cypermethrin residues did not exceed 0.02 mg/kg in the milk of dairy cattle exposed to 231 mg alpha-cypermethrin/animal/day. Alpha-cypermethrin residues in muscle, liver, and kidney were less than the limit of determination of the analytical method (0.05 mg/kg); the average alpha-cypermethrin residue found in the fat of dairy cattle fed at this level was approximately 0.16 mg/kg.

Alpha-cypermethrin residues did not exceed 0.08 mg/kg in the milk of dairy cattle exposed to 769 mg alpha-cypermethrin/animal/day. Alpha-cypermethrin residues in muscle, liver, and kidney were less than the limit of determination of the analytical method (0.05 mg/kg); the average alpha-cypermethrin residue found in the fat of dairy cattle fed at this level was approximately 0.87 mg/kg.

CA 6.4.3 Pigs

No feeding studies in pigs were performed.

CA 6.4.4 Fish

No feeding studies in fish were performed.

CA 6.5 Effects of Processing

In the framework of the original inclusion into Annex I according to Directive 91/414/EEC, the effect of processing on alpha-cypermethrin residues in barley and oilseed rape as well as cabbage and plum had been submitted.
Additional processing studies in barley and gherkins have been performed. These new studies will be summarized in the following. In addition, a published study from open peer-reviewed literature on the effect of processing in tomato is included.

An overview on the processing studies is presented in Table 6.5-1.

Table 6.5-1: Overview on processing studies

Crop / Test system	DocID / Reference	EU reviewed
Fruit (plum), vegetable(cabbage)	CY-790-060	Yes
Barley	AL-730-061 1993/7002041	Yes
Oilseed rape	AL-750-038	Yes
Oilseed rape	AL-750-042 2002/1004088	Yes
Processing hydrolysis	AL-790-046	Yes
Tomato	2005/1043620 Lin H.-M.et al., 2004a[1]	No
Barley	2007/1013068	No
Gherkins	2007-1011647	No

1 peer-reviewed open literature

CA 6.5.1 Nature of the residue

The effect of processing on the nature of alpha-cypermethrin residues was investigated during the EU Review. Studies were conducted using three test conditions: 20 minutes at 90°C and pH 4, simulating pasteurization; 60 minutes at 100°C and pH 5, simulating baking, brewing and boiling; and 20 minutes at 120°C, simulating sterilization.
Alpha-cypermethrin was found to be hydrolytically stable under the simulated processing conditions at pH 4 and 5 at 90°C and 100°C. However, alphacypermethrin was found to be susceptible to hydrolysis at the ester linkage at simulated processing conditions at pH 6 at 120°C resulting in the breakdown of the ester linkage to 3-phenoxybenzaldehyde (M310I018, CL 206969) and dichlorovinydimethylcarboxylic acid (DCVA, M310I001, CL 912554) as major degradates exceeding 10% of the applied dose. The major component of the residue was unchanged parent (83% - 90%).

Data on the fate of cypermethrin residues and formation of 3-phenoxybenzaldehyde during processing of tomatoes are available in peer reviewed open literature and submitted in the context of this dossier. A summary is given below.

Report: CA 6.5.1/1
Lin H.-M. et al., 2004a
Stability of the insecticide Cypermethrin during tomato processing and implications for endocrine activity
2005/1043620
Guidelines: none
GLP: no

Executive Summary

The thermal and pH stabilities of cypermethrin during food processing were investigated using tomato as a model food system and high-performance liquid chromatography as the analytical method. Cypermethrin was thermally unstable in aqueous conditions, where the hydrolysis of the pesticide was accelerated by heat. The mean proportion remaining after heating cypermethrin in water for 10 min was 66%, falling to 27% after 1 h. Similarly, thermal processing of canned tomatoes caused cypermethrin to degrade, with remaining levels in the final product ranging from 30 to 60% of the original. Cypermethrin was unstable at extreme pHs, with acid hydrolysis occurring faster than alkaline hydrolysis in phosphate buffers. The acidity of tomato paste (pH 4.3) caused cypermethrin levels to decrease by 30% within 12 days at 5°C. The studies indicate that cypermethrin residues are likely to degrade by hydrolysis during food processing, thus reducing the exposure of consumers to cypermethrin. 3-Phenoxybenzaldehyde, a hydrolysis breakdown product of cypermethrin, was detected in the tomato paste and from the heating of cypermethrin in water at 100°C.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material:

Description: Cypermethrin
Lot/Batch #: com. source, not stated
Purity: 96.8%
CAS#: 52315-07-8
Development code: not applicable
Spiking levels: 0.5, 1.5, 2 and 3.5 µg ml^{-1}

2. Test Commodity:

Crop: Tomato
Type: Fruiting vegetables, solanacea
Variety: fruit: Roma, paste and canned tomatoes: not stated
Botanical name: *Lycopersicon esculentum*
Crop parts(s) or processed commodity: fruit, paste, canned tomatoes
Sample size: not stated

B. STUDY DESIGN

1. Test procedure

Thermal stability of cypermethrin in aqueous conditions:
A 1.5 µg ml^{-1} cypermethrin aqueous solution was prepared by diluting required amounts of a cypermethrin standard solution with de-ionized water, where the percentage of methanol in the aqueous solution was not more than 2% (water solubility of cypermethrin is 9 $x10^{-3}$ mg l^{-1}). A total of 25 ml aqueous solution was poured into a 50ml capped Schott bottle, which was then placed in a steam bath (100°C). The bottle was allowed to equilibrate for 8 min before duplicate samples of 1 ml each were taken every 10 min for 1 h. The samples were analysed by HPLC, together with standard solutions of the 3-phenoxybenzyl compounds and an aqueous standard of 3-phenoxybenzaldehyde (prepared by diluting the standard solution with de-ionized water).

pH stability of cypermethrin in aqueous conditions:
A total of 2 µg ml^{-1} cypermethrin pH solutions were prepared by diluting required amounts of a cypermethrin standard solution with phosphate buffers of various pH. Samples of the solutions were measured by HPLC within 8 h of preparation, together with a 2 µg ml^{-1} cypermethrin aqueous solution. The solutions were analysed again after 12 days of storage in the dark at 5°C. The pH solutions, except for pH 7, were always adjusted to the pH range 6.5–7.5 by dropwise additions of concentrated hydrochloric acid or NaOH, before being subjected to HPLC analysis.

Effects of tomato paste acidity on stability of cypermethrin during tomato processing:
A total of 60 g commercial tomato paste (22–24% tomato solids) was fortified with 2.4 ml cypermethrin standard solution to obtain a spike concentration of 3.5 µg g^{-1}. The concentration of cypermethrin in the paste was determined before and after 12 days storage in the dark at 5°C.

Effects of thermal processing on stability of cypermethrin during tomato processing:
Thermal processing of canned peeled tomatoes was simulated by autoclaving unsealed cans of peeled tomatoes. The cans were emptied cans of whole peeled tomatoes (400 g), and were cleaned by boiling in water for 1 h, followed by drying in an oven for approximately 10 min. Peeled tomatoes were prepared by hand-peeling tomatoes, of the Roma variety, that were placed in boiling water for 1 min followed by immersion in cold water. The cans were filled with the peeled tomatoes and tomato juice that was liberated from tomatoes using a food mill. The filled cans were spiked with 0.2 ml cypermethrin standard solution to obtain a spike concentration of 0.5 µg g^{-1}, and with lids pushed shut they were autoclaved in a 40 litre Autoclave for 20 min at 110°C. A 50 ml Schott bottle containing 30ml 5 µg ml^{-1} cypermethrin aqueous solution was included in the autoclave. The autoclave was allowed to depressurize for approximately 5 h before the cans were removed.

Table 6.5.1-1: Conditions for thermal and pH stability study of cypermethrin

Processing represented	Matrix	pH	Temperature (°C)	Time
Model system aqueous stability	Water/≤2% methanol	Not stated	100	68 min
Model system pH stability	Phosphate buffer	2	5	12 days
	Phosphate buffer	4	5	12 days
	Phosphate buffer	7	5	12 days
	Phosphate buffer	10	5	12 days
Effect of tomato paste acidity	Tomato paste	4.3	5	12 days
Effect of thermal processing	Tomatoes, peeled and canned	Not stated	110	20 min
	Aqueous	Not stated	110	20 min

2. Description of analytical procedures

Analysis of cypermethrin aqueous and pH solutions was carried out by HPLC with diode array detection at 225 nm (UV). Separation was achieved on a SPHERI-5 octadecylsilane column, 220x4.6mm i.d., particle size 5 mm, with the mobile phase consisting of 70/30 (v/v) acetonitrile/water with a flow rate of 2ml min^{-1}. Sample injection volume was 50 µl. The limit of detection for cypermethrin in the aqueous solutions was 0.5 µg ml^{-1}. Recoveries were not reported for this method.

Tomato paste and autoclaved tomatoes were homogenized with acetonitrile, filtered and salted out with sodium chloride. The aqueous phase was discarded and an aliquot of the remaining acetonitrile was mixed with de-ionized water, followed by clean-up on a C18 SPE cartridge and a subsequent clean-up on a Florisil cartridge. The solvent of the eluate was evaporated , the residue redissolved in methanol and filtered. The determination of cypermethrin levels in processed tomatoes was carried out by HPLC with diode array detection at 225 nm (UV), as described for the aqueous and pH solutions. Recoveries and limit of quantitation were not reported for this method.

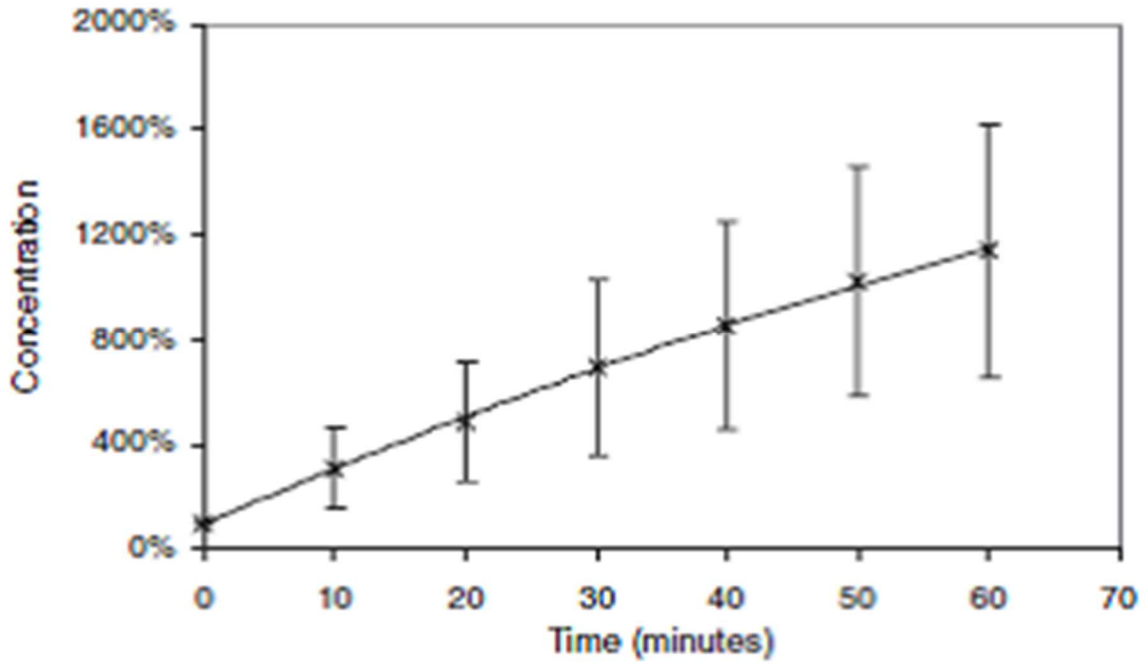
II. RESULTS AND DISCUSSION

Thermal stability of cypermethrin in aqueous conditions

Cypermethrin was thermally unstable in aqueous conditions, where the hydrolysis of the pesticide was accelerated by heat. The mean proportion remaining after heating cypermethrin in water at 100°C for 10 min was 66%, falling to 27% after 1 h.

Two breakdown products, compounds A and B, were observed in the HPLC chromatograms of cypermethrin. Compound B appeared only in some chromatograms of cypermethrin after 1 h of heating, while compound A was already present at a low level in cypermethrin aqueous solutions before heating, and its concentration increased over time during heating. The increase in the concentration of compound A during 60 minutes is shown in Figure 6.5.1-1.

Figure 6.5.1-1: Increase in the concentration of compound A from heating 1.5 µg ml^{-1} cypermethrin aqueous solution at 100°C.



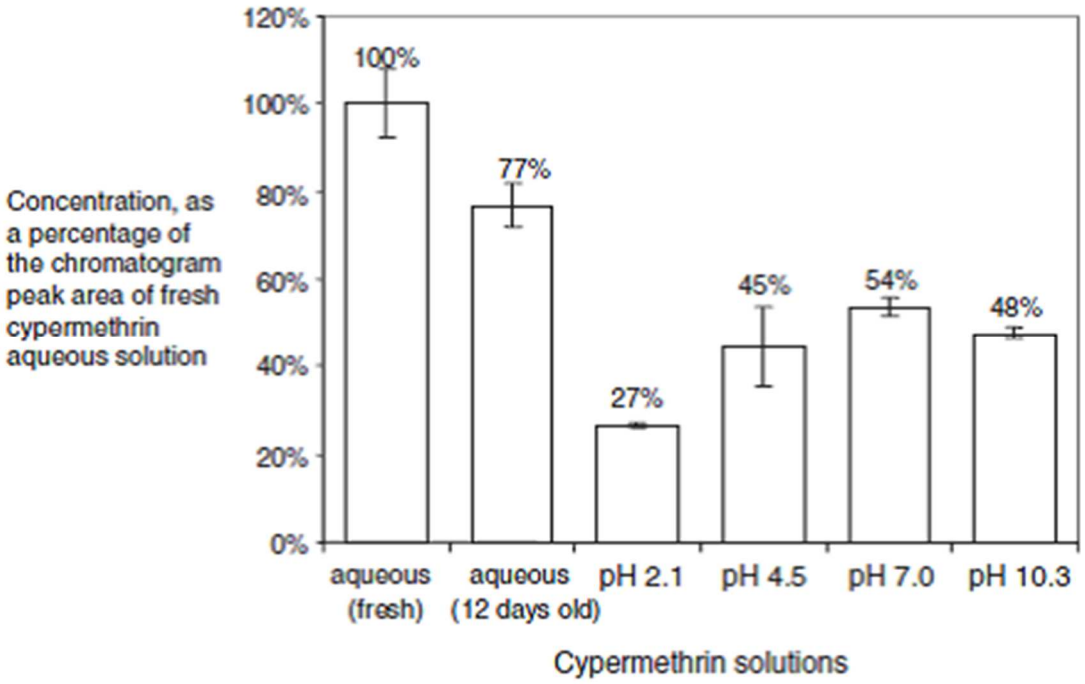
Error bars represent the standard deviation of the data from three experiments. (from Lin H.-M- *et al*., Food Additives & Contaminants: Part A, 22: 1, 15 - 22)

Compound A was identified as 3-phenoxybenzaldehyde, based on retention time and UV spectra comparisons with a 3-phenoxybenzaldehyde standard. The retention time of compound B did not match 3-phenoxybenzoic acid or 3-phenoxbenzyl alcohol.

pH stability of cypermethrin in aqueous conditions

The concentration of cypermethrin decreased by at least 46% at all pH after 12 days at 5°C (Fig. Figure 6.5.1-2 with the greatest decline at pH 2, followed by pH 4, pH 10 then pH 7. Therefore, acid hydrolysis of cypermethrin occurred to a greater extent than alkaline hydrolysis.
Phosphate appeared to influence the pH stability of cypermethrin because the decline in the concentration of cypermethrin after 12 days was higher in the phosphate buffer solutions compared with the aqueous solution. No 3-phenoxybenzaldehyde was found in the pH 4.5 phosphate buffer; no data on 3-phenoxybenzaldehyde were given for the other buffer solutions. The concentration of cypermethrin found after 12 days in buffered solutions at different pHs is shown in Figure 6.5.1-2.

Figure 6.5.1-2: Concentration of cypermethrin pH solutions after 12 days at 5°C.



Error bars represent the standard deviation of the data from three experiments three replicate solutions, except for the error bar for the fresh aqueous solution, which represents the standard deviation of duplicate HPLC measurements. (from Lin H.-M- *et al*., Food Additives & Contaminants: Part A, 22: 1, 15 - 22)

Stability of cypermethrin during tomato processing

The concentration of cypermethrin remaining in tomato paste of pH 4.3, after 12 days at 5°C, was 70% of the initial concentration, while in a pH 4.5 phosphate buffer after 12 days at 5°C only 45±9% of the initial concentration were found. Although the decrease in the concentration of cypermethrin in tomato paste was less than that of the aqueous model system, the breakdown product 3-phenoxybenzaldehyde was detected, according to its UV spectrum and retention time. The peak was significantly larger than that found in control tomato paste freshly spiked with cypermethrin. Table 6.5.1-2 shows the concentration of cypermethrin in tomato paste after 12 days at 5°C.

Table 6.5.1-2: Concentration of cypermethrin in tomato paste after 12 days at 5°C

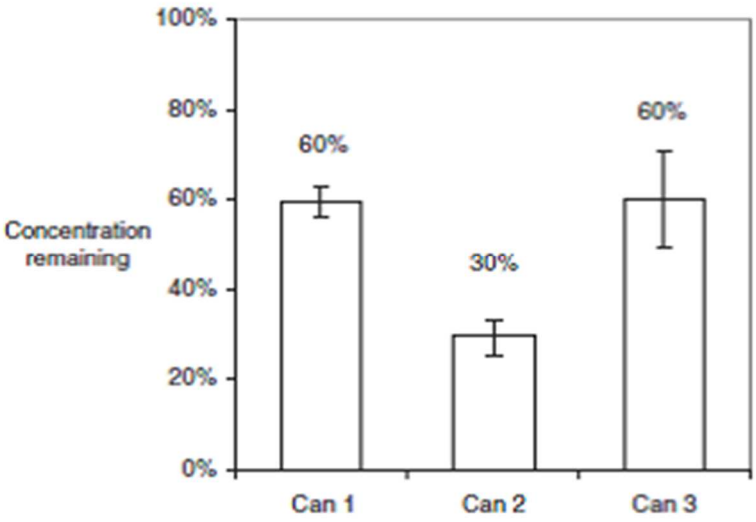
	Concentration (µ g^{-1})	Number of sample determinations
Before 12 days	3.5±0.2	3
After 12 days	2.4±0.2	2
Difference (%)	30±6	

Initial spike level 3.5 µg g^{-1}. The concentration after 12 days was significantly lower than the initial concentration; P=0.0037, one tail t-test, confidence level of 95%.

Effects of thermal processing

Peeled tomatoes were spiked with cypermethrin at a spike level of 0.5 µg g^{-1}. A significant loss of cypermethrin was observed in three cans autoclaved simultaneously, where remaining concentrations ranged from 30 to 60%. A 5 µg ml^{-1} cypermethrin aqueous solution that was autoclaved together with the cans was completely degraded (limit of detection for cypermethrin in the solution was 0.5 µg ml^{-1}). Chromatogram peaks matching the retention time of 3-phenoxybenzaldehyde were detected at very low levels in the autoclaved tomatoes. 3-Phenoxybenzaldehyde was detected in the aqueous solution, indicating that the aldehyde did not decompose under the high temperatures. The cypermethrin levels after autoclaving cans of peeled tomatoes at 110°C for 20 minutes are shown in Figure 6.5.1-3.

Figure 6.5.1-3: Cypermethrin levels after autoclaving cans of peeled tomatoes



Initial spike level 0.5 µg g^{-1}. Error bars for cans 1 and 3 represent the standard deviation of the data from three replicate sample determinations. The error bar for can 2 is the standard deviation of the data from duplicate determinations because an outlier concentration of <0.01 µg g^{-1} was excluded. (from Lin H.-M- *et al.*, Food Additives & Contaminants: Part A, 22: 1, 15 - 22)

III. CONCLUSION

The degradation rates of cypermethrin in the aqueous model systems differ from those of the tomato model system, where the hydrolysis rates of cypermethrin in tomato paste and during thermal processing were slower than that of the aqueous model systems. The results indicate that one major degradation product is 3-phenoxybenzaldehyde, which has a much lower acute oral toxicity in rats than the parent compound cypermethrin.

Executive Summary
During the 2004 growing season, four greenhouse trials in gherkins were conducted in Germany and the Netherlands in order to determine the magnitude and distribution of alpha-cypermethrin residues in a number of intermediate and end products after processing into canned gherkins. Gherkin plants were foliar sprayed twice with a soluble concentrate formulation of alpha-cypermethrin (code: BAS 310 41 I) at an exaggerated target rate of 0.075 kg alpha-cypermethrin/ha. The applications were made 14(±1) and 7(±1) days before harvest. The spray volume used was 400 l/ha. Gherkin fruit samples were collected immediately after the second application at growth stages between 69-87 and 6-8 days thereafter at growth stages between 71-89. The specimen were processed into canned gherkins and the intermediate fractions washed gherkins, wash water and vegetable stock using using simulated household and industrial processing procedures.

At 0 days after the last application, the alpha-cypermethrin residues in gherkin fruit were between 0.012 and 0.066 mg/kg. In the gherkins taken for processing 6-8 days after the last application, these residues declined to 0.015 - 0.038 mg/kg. In wash water, washed gherkins and vegetable stock, the transfer factors were below 1. In two out of four canned gherkin specimens, a slight increase (transfer factors 1.33 and 1.07, respectively) of the alpha-cypermethrin residues was observed.

B. STUDY DESIGN AND METHODS

1. Test procedure

Field phase

During the 2004 growing season, four greenhouse trials in gherkins were conducted in Germany (Brandenburg; ACK/01/04 and ACK/25/04) and the Netherlands (Limburg; AGR/01/04 and AGR/02/04) in order to determine the magnitude and distribution of alpha-cypermethrin residues in a number of intermediate and end products after processing (washed gherkins, wash water, canned gherkins, vegetable stock).

Two of the trials consisted of two plots, one untreated and one treated (ACK/01/04 and AGR/01/04); the other two (ACK/25/04 and AGR/02/04) consisted of one treated plot each.

Gherkin plants (varieties: Serena F1 in the German trials and Harmonie in the Dutch trials) were foliar sprayed twice with a soluble concentrate formulation of alpha-cypermethrin (code: BAS 310 41 I) at an exaggerated target rate of 0.075 kg alpha-cypermethrin/ha. Actual rates were within +/10 % of the nominal rate. This exaggerated treatment rate was used in an effort to generate finite alpha-cypermethrin residues in gherkins so that the distribution of the residue in the processed fractions could be better quantified.

The applications were made 14(±1) and 7(±1) days before harvest. The spray volume used was 400 I/ha. Gherkin fruit samples were collected immediately after the second application at growth stages between 69-87 and 6-8 days thereafter at growth stages between 71-89. All specimens were frozen within 24 hours of being taken, and remained frozen at or below -18°C, including during transportation, until analysis. The maximum storage interval from sampling until extraction was 278 days.

Target application rates and timings for gherkins

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2004	4	2	G	BAS 310 41 I (SC)	alpha-cypermethrin	0.075	400	14±1 and 7 ±1 days before harvest

Processing phase

Sorting
Damaged and rotten gherkins were sorted out by hand and subsequently discarded. Only healthy gherkins were used for processing.

Washing
A quantity of gherkins between 2 - 10 kg from each field trial was cleaned with tap water (20° C) using a brush. For that, the gherkins of every plot were divided into 3 batches. For the washing of each batch, about 3 L of tap water were used, out of which 1 L was put aside after the washing of each batch. 1 L of fresh water was used for the rinsing of the cleaned gherkins in a sieve. This rinsing water was added to the remaining 2 L of water for the washing of the next batch of gherkins. This procedure was repeated for the 3 portions of each gherkin specimen. The wash water and the rinsing water of each specimen were combined and indicated as "wash water". This procedure resulted in approx. 6 L of wash water used for the washing of the gherkin specimens.
Specimens of wash water for residue analysis were taken, filled into 1 L PE bottles with screw caps and stored deep-frozen. Also specimens of washed gherkins for residue analysis were taken, filled into PE bags and stored deep-frozen. The remaining washed gherkins were used for the processing to canned gherkins.

Canning
The washed gherkins were filled into 1 L jars (approx. 450 g per jar). Throughout the study, the term "canned gherkins" is used, although gherkins were filled into jars.
A hot solution of tap water (3.75 kg), table salt (150 g), sugar (200 g) and vinegar (1000 g, 10 %) was prepared, which was used to fill the jars to the brim (approx. 450 g) at a temperature of about 85°C. The jars were steamed at the top for 15 seconds (head space vaporization) and then immediately closed by a lid. The subsequent pasteurization was carried out by heating the jars to 90°C and keeping them at that temperature for 20 minutes. They were then allowed to cool down in an autoclave to 75 °C, which took about 13 to 27 minutes, after which the jars were placed in a water bath and allowed to cool down to ambient temperature (35 to 90 minutes).
The jars were then opened and the gherkins were separated from the vegetable stock using a sieve. A specimen each of the canned gherkins and the vegetable stock was taken for residue analysis and stored deep-frozen.

2. Description of analytical procedures

The specimens were analysed for residues of alpha-cypermethrin using BASF method No. 567/0. The limit of quantification (LOQ) of the method was 0.01 mg/kg.
Principle of the method:
BAS 310 I (alpha-cypermethrin) is extracted with a 70:25:5 methanol/water/hydrochloric acid mixture. After centrifugation, an aliquot of the extract is partitioned into cyclohexane. Silica gel SPE column is used for further purification, if required. Final determination is performed by LC/MS/MS.

Table 6.5.3-1: Procedural recoveries

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
gherkin fruit, wash water, vegetable stock, washed gherkins, canned gherkins	0.01-1.0	15	91.1	10.3	11.3

II. RESULTS AND DISCUSSION

Directly after application, the alpha-cypermethrin residues in the gherkin specimens ranged from 0.012 to 0.066 mg/kg and declined to 0.015 to 0.038 mg/kg in the gherkins taken for processing, at 6 - 8 days after the last application. In washed gherkins, a reduction of alpha-cypermethrin residues was observed, with levels ranging between 0.009-0.013 mg/kg (mean transfer factor 0.60), while in wash water, residues of alpha-cypermethrin between <0.01-0.016 mg/kg were detected (mean transfer factor 0.59).

In two out of four canned gherkin specimens, a slight increase (transfer factors 1.33 and 1.07, respectively) of the alpha-cypermethrin residues was observed; the residue levels ranged between 0.013-0.020 mg/kg, and the mean transfer factor was 0.86.
In vegetable stock, no residues above the limit of quantitation were detected (all <0.01 mg/kg); the mean transfer factor was <0.53 mg/kg.

No residues at or above the LOQ were detected in the untreated RAC specimens or in the processed fractions.

The alpha-cypermethrin residues in gherkins and processed products as well as the corresponding transfer factors are summarized in Table 6.5.3-2, whereby the transfer factors in the gherkins (RAC) were set as 1:

Table 6.5.3-2: Summary of alpha-cypermethrin residues and transfer factors

Matrix	Residue alpha-cypermethrin mg/kg				Transfer factor alpha-cypermethrin				
	ACK/ 01/04	ACK/ 25/04	AGR/ 01/04	AGR/ 02/04	ACK/ 01/04	ACK/ 25/04	AGR/ 01/04	AGR/ 02/04	mean

1) days after last application
2) 0.009 mg/kg is reported as the actual calculated residue, not as < 0.01.

III. CONCLUSION

At 0 days after the last application, the alpha-cypermethrin residues in gherkin fruit were between 0.012 and 0.066 mg/kg. In the gherkins taken for processing 6-8 days after the last application, these residues declined to 0.015 - 0.038 mg/kg. In wash water, washed gherkins and vegetable stock, the transfer factors were below 1. In two out of four canned gherkin specimens, a slight increase (transfer factors 1.33 and 1.07, respectively) of the alpha-cypermethrin residues was observed.

Report:	CA 6.5.3/2 Mamouni A., 1993a Residue analysis of Alphacypermethrin (SAG 30505) in summer barley and its processed fractions after brewing (field study SKG-9249) AL-730-061
Guidelines:	BBA IV 2, BBA Merkblatt Nr. 58 (1983)
GLP:	yes (certified by Eidgenoessisches Departement des Innern, Bern, Schweiz)

Executive Summary

Two trials in spring barley were performed in Germany in the year 1992. Barley plants were treated with alpha-cypermethrin 100 g a.s./L OD (OSK, "ölhaltiges Suspensionskonzentrat") three times at a rate of 15 g a.s./ha. The growth stage of the plants at the last application was between 71 (Watery ripe: first grains have reached half their final size) – 75 (Medium milk: grain content milky, grains reached final size, still green). Samples were taken 0 and 35 days after the last application.

A part of the harvested barley was used to brew beer and to obtain by-products of the brewing process such as malt, malt germ, beer yeast, spent barley and trub.

The results of this study clearly demonstrate that residues in or on the raw agricultural commodity barley grain are not transferred to spent yeast and the final consumer product beer. No residues above limit of quantitation (0.01 mg/kg) of alpha-cypermethrin could be found in beer. The mean transfer factor for beer was <0.35 for alpha-cypermethrin residues.

Variety:	Alexis, Apex
Botanical name:	*Hordeum vulgare*

Crop parts(s) or processed commodity: ears, grain, spent barley, malt, malt germs, trub, yeast, beer

Sample size: ear, rest of plant: 1-2.3 kg;
grain: 10-22 kg
malt: approx.. 800 mL, equivalent to 350 g
malt germ: all germ material from individual malt sample

spent barley: 1.3-1.6 kg
trub material: all trub separated from individual sample
yeast: all yeast remaining after fermentation of individual sample
beer: 9-10 bottles à 0.33 L

B. STUDY DESIGN AND METHODS

1. Test procedure

Field phase

During the growing season of 1992, two trials in spring barley were performed in Germany. Barley plants were treated with alpha-cypermethrin 100 g a.s./L OSK three times at a rate of 15 g a.s./ha. The applications were made 86-87, 58-67 and 35 days before harvest in a spray volume of 400 litres.
The growth stage of the plants at the last application was between 71 (Watery ripe: first grains have reached half their final size) – 75 (Medium milk: grain content milky, grains reached final size, still green). Samples were taken 0 and 35 days after the last application.

Table 6.5.3-3: Target application rates and timings for barley

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
1992	2	3	F	Alpa-cypermethrin 100 g/L OSK	alpha-cypermethrin	0.0150	400	86-87, 58-67 and 35days before harvest

Processing phase:

Malting and beer production was conducted in the pilot plants of Weissheimer Malz in D-56610 Andernach and in the pilot plant of Binding Brauerei AG in D-60598 Frankfurt am Main. The pilot plants were designed to perform all steps of malting and beer brewing on a small scale and to simulate the same process principles as used in industrial malthouses and breweries.

Beer was obtained from barley by malting and brewing of the malt. Each batch of samples was processed separately to minimize the risk of cross contamination.

Malting:
The complete barley sample was passed through the grader for size grading(>2.2->2.5 mm. The untreated barley was graded before the barley treated with alpha-cypermethrin was fractionated. The graded barley was weighed into sample cylinders, the cylinders were closed with the sieve and placed into the steeping tank. Steeping was performed for 44 hours at a target temperature of 14°C. At the end the product was allowed to rest for an additional 4 hours.
The samples were then germinated under aeration with air adjusted to a temperature of 14°C for 96 -144 hours. After germination, the samples underwent kilning at max. 80°C for 15 hours. Finally, the malt was degerminated sieve to remove the malt germ.

Brewing:
The malt was ground with a two-roll mill and mashed into decarbonised water which was heated to 52°C. The total time of the mashing procedure was between 150 and 163 minutes.
At the end, the mash was drained off into the heated lauter tub (76°C). The wort was separated from the spent barley in the lauter tub by filtration, the spent grain was washed and the washings were combined with the filtrate. The wort was heated by passing steam through the heat exchanger and hop extract was added to the wort within 5 minutes before and 2 minutes after beginning of boiling. 75 minutes after the beginning of boiling, trub material had usually coagulated sufficiently and the trub was separated from the wort. The trub was either separated in the whirlpool or in case of insufficient coagulation by filtration.
The wort was cooled down to 18.2 to 24.5°C within 110 to 203 minutes and then pumped off into a sterilized fermentation vessel. Air was passed in to saturate the wort with oxygen. When the wort had reached a temperature of 14-18°C, yeast slurry was added and the fermentation process allowed to proceed under dark conditions for seven days at approximately 10°C. After removal of the yeast, carbon dioxide was forced under pressure into the storage container before the container was placed into the cooling box at approximately 5-6.3°C for five days. After this period the container was stored at 0°C for ten days. Finally, the beer was clarified by filtration and filled into bottles.

All procedures were conducted using the same technical principles as commonly used in industrial malthouses and in the brewing industry.

2. Description of analytical procedures

All specimens were analysed using an adaptation of analytical method SAMS 351-1.
The analytical material was homogenized with acetone/n-hexane (1 + 1 v/v). This mixture was partitioned into n-hexane, and the n-hexane layer was rotary-evaporated to dryness. The residue was dissolved in n-hexane and cleaned-up by column chromatography on activated Florisil®. In addition, a second clean-up step on silica gel 60/activated carbon was performied for trub, yeast, malt and beer samples. The eluates were evaporated to dryness and dissolved in dodecane/acetone (9 + 1 v/v). Alpha-cypermethrin was determined by electron capture detection (ECD) with a LOQ of 0.01 mg/kg.

Table 6.5.3-4: Procedural recoveries

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)

* Corrected = Signal of fortified sample minus signal of control sample used for fortification. Corrected recovery was used for calculation of overall mean recovery.

II. RESULTS AND DISCUSSION

The control (untreated) samples of the raw agricultural commodity (RAC) and of the processing products contained residue concentrations below the routine limit of determination of 0.01 mg/kg for both trials.

Immediately after the last of three applications at 0.015 kg alpha-cypermethrin/ha, residues in treated ears were 0.416 and 0.700 mg/kg, while 0.319 and 0.517 mg/kg, respectively, were found in barley plant. Residues in grain were 0.019 and 0.060 mg/kg, respectively, at35 days after last application.

In the malt / beer production the following residues were observed: In malt, residues of alpha-cypermethrin were reduced compared to RAC (0.013 and 0.014 mg/kg). In malt germs, residues of 0.011 and 0.026 mg/kg were observed. In spent barley, residues of 0.014 and 0.032 mg/kg were determined. The highest mean transfer factors were determined malt germs and spent barley (0.78 and 0.96, respectively), followed by malt (0.48).

No residues above the limit of quantitation were found in treated trub, yeast and beer samples from both trials (all <0.01 mg/kg). The transfer factors ranged between 0.17 and 0.53 (mean 0.35)

The residue levels detected in the treated specimens and their processed fractions as well as the calculated transfer factors are summarized in Table 6.5.3-5.

Table 6.5.3-5: Summary of alpha-cypermethrin residues in barley and transfer factors

Matrix	Residue alpha-cypermethrin mg/kg		Transfer factor** alpha-cypermethrin		
Trial	**9249-01**	**9249-02**	**9249-01**	**9249-02**	**Mean**
Ear (0 days after last application)	0.700	0.416	-	-	
Rest of plant (0 days after last application)	0.517	0.319	-	-	
Grain (35 days after last appl.)	0.060	0.019	-	-	
Malt	0.013	0.014	0.22	0.74	0.48
Malt germs	0.011	0.026	0.18	1.37	0.78
Spent barley	0.014	0.032	0.23	1.68	0.96
Trub	<0.01	<0.01	0.17	0.53	0.35
Yeast	<0.01	<0.01	0.17	0.53	0.35
Beer	<0.01	<0.01	0.17	0.53	0.35

* For calculation purposes, "< 0.01" is set as 0.01

III. CONCLUSION

The results of this study clearly demonstrate that residues in or on the raw agricultural commodity barley grain are not transferred to spent yeast and the final consumer product beer. No residues above limit of quantification of alpha-cypermethrin could be found in these fractions. The transfer factors ranged between 0.17 to 0.53 for alpha-cypermethrin residues.

Report:	CA 6.5.3/3 Harant H., 2007a Determination of residues of Alpha-Cypermethrine in spring barley and its processing products after two applications of BAS 310 41 I in Germany 2007/1013068
Guidelines:	EEC 7029/VI/95 rev. 5, BBA IV 3-3, IVA Guideline I-III (1992)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary
During the growing season 2004, four field trials were conducted in representative spring barley growing areas in Germany in order to generate specimens for analysis to determine the residues of alpha-cypermethrin in plants without roots and grain as well as after processing into beer and pot barley and the respective intermediate fractions.
The test item BAS 310 41 I, a SC formulation of alpha-cypermethrin (100 g alpha-cypermethrin/L) was foliar applied twice at an exaggerated target rate of 1.5 L product/ha (nominal a.s./ha: 0.150 kg alpha-cypermethrin) for each application, resulting in a seasonal target rate of 300 g a.s./ha (nominal). The applications were made ~~42~~ 49 (±1) days and ~~35~~ 42 (±1) days before the planned harvest date, using a spray volume of 300 L/ha.
Specimen were collected at the day of the last application and at harvest (41-43 days after the last application) for analysis of the raw.agricultural commodity as well as for processing.
The specimen were processed into beer and pot barley and the intermediate fractions brewing malt, malt culms, spent grain, spent hops (flocs), spent yeast, pearling dust/bran and flour using simulated industrial processing procedures.
The results of this study clearly demonstrate that residues in or on the raw agricultural commodity barley grain are not transferred to spent yeast and the final consumer product beer. No residues above limit of quantitation of alpha-cypermethrin could be found in this fraction. The mean transfer factor was 0.05 for alpha-cypermethrin residues.
In pot barley residue values of alpha-cypermethrin were found ranging from 0.01 to 0.04 mg/kg with a mean transfer factor of 0.10.

B. STUDY DESIGN AND METHODS

1. Test procedure

Field phase

During the growing season 2004, four field trials were conducted in representative spring barley growing areas in Germany in order to generate specimens for analysis to determine the residues of alpha-cypermethrin in plants without roots and grain as well as after processing in brewing malt, malt culms, spent grain, spent hops (flocs), spent yeast, beer, pot barley, pearling dust/bran and flour.

The test item BAS 310 41 I, a SC formulation of alpha-cypermethrin (100 g alpha-cypermethrin/L) was foliar applied twice at an exaggerated target rate of 1.5 L product/ha (nominal a.s./ha: 0.150 kg alpha-cypermethrin) for each application, resulting in a seasonal target rate of 300 g a.s./ha (nominal). This exaggerated rate was used in an attempt to generate residue levels sufficiently above the method limit of quantification (LOQ) in the raw agricultural commodity. The applications were made ~~42~~ 49 (±1) days and ~~35~~ 42 (±1) before the planned harvest date, using a spray volume of 300 L/ha.

Two of the trials consisted of two plots, one untreated and one treated (FR/01/04/40 and FR/01/04/70); the other two (FR/01/04/20 and FR/01/04/50) consisted of one treated plot each.

Specimen of barley grain were collected at the day of the last application and at harvest (at growth stage 89) for analysis of the raw.agricultural commodity as well as for processing.

The specimen for RAC analysis were frozen within a maximum of 6 hours. The specimens for processing were stored at room temperature until the processing start.

Table 6.5.3-6: Target application rates and timings for barley

Year	No. of Trials	No. of Appl.	F P or G	Test Item	Active Substance	Appl. Rate (kg a.s./ha)	Water Volume (L/ha)	Target Date/ Timing
2004	4	2	F	BAS 310 41 I (SC)	alpha-cypermethrin	0.150	300	42 ±1 and 35 ±1 days before harvest

Processing phase: Beer processing

Malting:

Before malting was started, all specimens were sieved to remove contaminants and to grade the barley grain into kernels with the same minimum size (sieve mesh: 2.5 mm). The steeping process was conducted as a combined wet and dry steeping. Sieved barley grain was transferred in a special steeping vessel. The steeping temperature was 13-15 °C and the steeping degree was 44.8-44.9% (water content). The subsequent germination was performed for approximately 118-119 hours at 13-15 °C and a relative air humidity of 80-100% under continuous turning. After kiln-drying to a residual water content of 4.0% and removal of the sprouts by a trimmer, the treated malt was stored for 35-43 days at ambient conditions (room temperature) until brewing was started.

Mashing, boiling and fermentation:

Mashing was conducted with tap water in a heatable tun using the infusion method (whole amount of water and malt was processed within one step). The mash was heated in a stepwise temperature increase process to a final temperature of 76-78°C. The whole mashing process took 102-110 minutes. After mashing, the wort was separated from the insoluble malt components (spent grains). The extract remaining in those spent grains was extracted by washing them with hot water. The wort separation was done using a refining fat. After the addition of commercial hop, the wort was boiled (approx. 90 min at normal pressure), then the trub was separated in a whirlpool, causing the sludge to deposit on the bottom in the shape of a cone. For cooling and ventilating the wort, plate heat exchangers and an intra-plant circulation were used. By adding oxygen until saturation, the conditions were prepared for fermentation.

In the pilot plant the classical primary fermentation (low fermentation) was carried out using bottom fermenters (approx. 50 L capacity). Fermentation heat was dissipated by means of room ventilation.

As soon as the extract content of the fermenting young beer was 2 % higher than the final attenuation, it was transferred into casks through hoses. After fermentation, the yeast deposited on the tank bottom.

For maturation, the young beer was stored for 2 days at room temperature (warm maturation) in casks. Then, under pressure the young beer was stored at approx. 0-2 °C for about 4 weeks (cold maturation). Finally, the rack beer was filtered using a filter combination.

Processing phase: Pot barley processing

The optimal moisture to mill barley grains is approx. 14 %. In order to obtain acceptable milling results a moisture content of up to 16 % is acceptable. The moisture content of the specimens of the special processing part ranged in a lower moisture level (12.8-13.0%, treated samples). Therefore, the grain was processed after damping which resulted in a moisture content of 14.9-15.1% (treated samples).
The specimens were hulled using a "Schule-Vertikal-Schälmaschine". Each specimen was hulled until the stipulated abrasion for pot barley of 20-25 % was reached. The degree of abrasion was determined by the proportion of pot barley with respect to the total portion of purified grain used for the hulling process. As a side product from hulling pearling dust/bran and flour were derived.

2. Description of analytical procedures

Samples of barley grain, malt, pearling dust and pot barley were analysed for alpha-cypermethrin with BASF analytical method no. 567/0 using HPLC-MS/MS for quantitative determination. All other matrices were analysed with BASF analytical method no. 567/1 using GC/MS for quantitative determination.

Principle of BASF method no. 567/0:
BAS 310 I (alpha-cypermethrin) is extracted with a 70:25:5 methanol/water/hydrochloric acid mixture. After centrifugation, an aliquot of the extract is partitioned into cyclohexane. A silica gel SPE column is used for further purification, if required. Final determination is performed by HPLC-MS/MS using the ammonium adduct of cypermethrin.
The limit of quantitation (LOQ) of the method for alpha-cypermethrin is 0.01 mg/kg.

Principle of BASF Method No. 567/1:
BAS 310 I (alpha-cypermethrin) is extracted with a 70:25:5 methanol/water/hydrochloric acid mixture in case of beer and spent hops and with 95:5 methanol/hydrochloric acid in case of plant w/o root, spent grain, malt culms, spent yeast and flour. After centrifugation, an aliquot of the extract is partitioned into cyclohexane. A silica gel SPE column is used for further purification. Final determination is performed by GC-MS. The limit of quantitation (LOQ) of the method for alpha-cypermethrin is 0.01 mg/kg.

Table 6.5.3-7: Procedural recoveries

Matrix	Fortification Level (mg/kg)	Summary Recoveries			
		n	Mean (%)	SD (+/-)	RSD (%)
Method No. 567/0		alpha-cypermethrin			
grain, malt, pot barley, pearling dust/bran	0.01, 0.1	8	89.9	13.9	15.4
Method No. 567/1		alpha-cypermethrin			
Plant w/o roots, malt culms, spent grain, spent hops, spent yeast, beer, flour	0.01, 0.1, 1.0	64	94.3	11.3	12.0

II. RESULTS AND DISCUSSION

In the control samples, two cases occurred where residues were found: in trial FR 01/04/40 alpha-cypermethrin was found in plant w/o roots (0.02 mg/kg) and spent hops (0.07 mg/kg). In all other control samples no residues of alpha-cypermethrin at or above the limit of quantitation were found, which proves that in general no interferences of the specimen material with the analytical procedure occurred.

The amounts of alpha-cypermethrin in spring barley grain treated at an exaggerated rate and collected 41 to 43 days after last application ranged from 0.11 to 0.33 mg/kg.
In the malt / beer production the following residues were observed: alpha-cypermethrin in amounts comparable to the RAC was found in malt (0.12 to 0.19 mg/kg). With residues between 0.32 and 1.12 mg/kg, a slight concentration could be seen in malt culms. Low amounts of alpha-cypermethrin were found in spent grain and spent hops (0.13 to 0.26 mg/kg and 0.02 to 0.07 mg/kg respectively). Comparable to the residues found the highest mean transfer factor was determined for malt culms (3.18) followed by spent grain (0.95), brewing malt (0.72) and spent hops (0.22).
In spent yeast and the final consumer product beer, no residues above the limit of quantitation of alpha-cypermethrin could be found. The transfer factors ranged between 0.03 to 0.09 for alpha-cypermethrin residues.
In pot barley residue values of alpha-cypermethrin were found ranging from 0.01 to 0.04 mg/kg with a mean transfer factor of 0.10. Pearling dust/bran and flour had higher residue values with 0.72 to 1.62 mg/kg as well as 1.35 to 2.17 mg/kg, respectively. The mean transfer factor determined for pearling dust/bran is 5.79 and for flour 8.67.

The residue levels detected in the treated specimens and their processed fractions as well as the calculated transfer factors are summarized in Table 6.5.3-8.

Table 6.5.3-8: Summary of alpha-cypermethrin residues in barley and transfer factors

Matrix	DALA	Residue alpha-cypermethrin mg/kg				Transfer factor alpha-cypermethrin				
Trial*		FR 01/04/40	FR 01/04/70	FR 01/04/20	FR 01/04/50	FR 01/04/40	FR 01/04/70	FR 01/04/20	FR 01/04/50	mean

* For calculation purposes, "< 0.01" is set as 0.01

III. CONCLUSION

The results of this study clearly demonstrate that residues in or on the raw agricultural commodity barley grain are not transferred to spent yeast and the final consumer product beer. No residues above limit of quantification of alpha-cypermethrin could be found in these fractions. The transfer factors ranged between 0.03 to 0.09 for alpha-cypermethrin residues. With residues between 0.32 and 1.12 mg/kg, a slight concentration could be seen in malt culms. Low amounts of alpha-cypermethrin were found in spent grain and spent hops (0.13 to 0.26 mg/kg and 0.02 to 0.07 mg/kg, respectively). Comparable to the residues found the highest mean transfer factor was determined for malt culms (3.18) followed by spent grain (0.95), brewing malt (0.72) and spent hops (0.22).
In pot barley residue values of alpha-cypermethrin were found ranging from 0.01 to 0.04 mg/kg with a mean transfer factor of 0.10. Pearling dust/bran and flour had higher residue values with 0.72 to 1.62 mg/kg as well as 1.35 to 2.17 mg/kg, respectively. The mean transfer factor determined for pearling dust/bran is 5.79 and for flour 8.67.

This entry is taken from public literature and was not included in the study list of the application.

Report: CA 6.5.3/4
Kang S.-M.,Lee M.-G., 2005a
Fate of some pesticides during brining and cooking of chinese cabbage and spinach
2005/1043600
Guidelines: none
GLP: no

Executive Summary

In 2002, Chinese cabbages and spinach were cultivated in a greenhouse in two separate field lots according to good agricultural practices and subjected to pesticide application. Pesticide solutions were sprayed onto the crops once a week. Cypermethrin was applied at a rate of 0.24 kg as/ha or 0.30 kg as/ha on Chinese cabbage and at a rate of 0.13 kg as/ha or 0.17 kg as/ha on spinach. Chinese cabbages were harvested 3 days after ninth and eleventh pesticide applications. Spinach was harvested on the 7th and 2nd day after three applications.
The crops were subjected to brining, heat-cooking and blanching to determine residue or transfer ratios of the pesticides.
The reduction of cypermethrin residues in the brined Chinese cabbage was 13% and in the heat-cooked Chinese cabbage 0%. The reduction of cypermethrin residues in the blanched spinach was 13% and in the heat-cooked spinach 8%.

I. MATERIAL AND METHODS

A. MATERIALS

1. **Test Material:** Cypermethrin
   Description: Cypermethrin 5% (EC)
   Lot/Batch #: not reported
   Purity: not reported
   CAS#: 52315-07-8
   Development code: not applicable
   Spiking levels: between 0.5 and 2.0 mg/kg

2. **Test Commodity:** Brassica vegetables, leafy vegetables
   Crop: Chinese cabbage, spinach
   Type: not reported
   Variety: not reported
   Botanical name: Brassica rapa, spinacia oleracea L.
   Crop parts(s) or processed
   Commodity: Chinese cabbage (RAC) and processed commodities: brining and head-cooking; spinach (RAC) and processed commodities: blanching and heat-cooking
   Sample size: Brining of Chinese cabbage: 500 g, heat-cooking of Chinese cabbage: 300 g, blanching of spinach: 200 g, heat-cooking of spinach 200 g

B. STUDY DESIGN AND METHODS

1. Test procedure

In 2002, Chinese cabbages were cultivated in a greenhouse in two separate field lots according to good agricultural practices and subjected to pesticide application. Mixed pesticide solutions, including two or three pesticides, were sprayed onto the cabbages once a week. Cypermethrin was applied at a rate of 0.24 kg as/ha or 0.30 kg as/ha. The vegetables were harvested 3 days after ninth and eleventh pesticide applications to obtain low and high pesticide-level samples, respectively.
In 2002, spinach was cultivated in a greenhouse in two separate field lots according to the good agricultural practices and subjected to pesticide application. Pesticide solutions were sprayed onto the spinach once a week. Cypermethrin was applied at a rate of 0.13 kg as/ha or 0.17 kg as/ha. To obtain low and high pesticide-level samples, the vegetables were harvested on the 7^{th} and 2^{nd} day after three applications, respectively.
Other pesticide formulations (EC) applied during the growth of Chinese cabbage and spinach were chlorpyrifos 20%, diazinon 34%, dichlorvos 50%, EPN 45%, endosulfan 35%, deltamethrin 1% and fenvalerate 5%.

Brining and heat-cooking of Chinese cabbage: A head of Chinese cabbage weighing about 2.5 kg was longitudinally cut into eight portions. Two portions (equivalent to 500 g) were then soaked in 2 L of 8% saline at 20 °C, after 4 hours drained on a sieve for 30 min, washed by hands in 1 L tap water for 10 seconds, and drained again for 30 minutes. The brine-soaking resulted in 428 g brined cabbage, 1.932 mL waste brine, and 1.010 mL water-washings.
One portion of the longitudinally-cut cabbage weighing about 300 g was further cut into 5-cm pieces and cooked for 20 minutes with two stirred in 1.2 L covered boiling water pot. The pot was left standing for 30 minutes to cool down to 60 °C. After draining for 30 minutes, 240 g cabbage solids and 1.013 mL cooked fluid were obtained.

Blanching and heat-cooking of spinach: About 200 g spinach leaves were dipped into 1 L boiling water for 2 minutes and drained on a sieve for 30 minutes. The blanching resulted in 228 g spinach solids and 875 mL blanched fluids.
For heat-cooking, about 200 g of spinach bunches were cut into four portions cross-wise and cooked in 1 L tap water for 15 minutes as with the Chinese cabbage. The heat-cooking resulted in 218 g spinach solids and 810 mL cooked fluid.

2. Description of analytical procedures

The raw vegetable samples were cleaned by removing roots and spoiled leaved, and subjected to residue analysis. Solid liquid samples obtained in duplicate runs were extracted using appropriate solvent systems and subjected to residue analysis in triplicates.
Gas chromatograph equipped with an HP-5 column was used to detect organophosphorus pesticides with a flame photometric detector, and organochlorine and synthetic pyrethroids with an electron capture detector.
Samples for residue analysis were spiked with standard pesticides at 0.5-2.0 mg/kg of vegetable or liquid samples and subjected to routine analysis in triplicates. The recoveries for cypermethrin were between 94 and 110%.

II. RESULTS AND DISCUSSION

The residue levels of cypermethrin in the treated Chinese cabbage and spinach specimens are shown in Table 6.5.3-9. Out of two different samples, those with residue concentrations nearer the Korea MRLs were chosen and subjected to reduction studies.

Brining process of Chinese cabbage:
Residue concentrations of raw and brined cabbages, and brine obtained after soaking and washings of brined cabbages were determined. Weight or volumes of the samples were measured, and the total amount of residues in analyzed samples was calculated. The residue ratios of samples were calculated as the total amount of residues on the basis of raw cabbage as 100, and difference from 100% was regarded as the loss during brining process.
The residue ratios of cypermethrin in the brined cabbage was 112%. The transfer ratio of cypermethrin into the soaking brine or washings after brining was 10% and 7%, respectively. No loss of residues was observed during brining.

Heat-cooking of Chinese cabbage
Residue concentrations of the solid cabbage and cooking fluid were analyzed. The residue ratios were calculated in the same way as for the brining process.
The residue ratio of cypermethrin in the heat-cooked cabbage was 119%, the transfer ratio into the fluid or loss during cooking was zero, suggesting that cypermethrin do not decompose or vaporize during cooking.

Blanching of spinach
Residue concentrations of the solid spinach and blanching fluid were analyzed. The residue ratios were calculated in the same way as for the brining process.
The residue ratio of cypermethrin in blanched spinach was 87%, the transfer ratio into the blanching water was zero and the loss in blanching was 13%.

Heat-cooking of spinach:
Residue concentrations of the solid spinach and cooking fluid were analyzed. The residue ratios were calculated in the same way as for the brining process.
The residue of cypermethrin in heat-cooked spinach was 92%, the transfer ratio into the fluid was zero and the loss in cooking was 8%.

The residue and transfer ratios of cypermethrin in processed fractions of Chinese cabbage and spinach are presented in Table 6.5.3-10.

Table 6.5.3-11 shows the % disappearance of cypermethrin residues in the raw vegetables during processing. The reduction of cypermethrin residues in the brined Chinese cabbage was 13% and in the heat-cooked Chinese cabbage 0%. The reduction of cypermethrin residues in the blanched spinach was 13% and in the heat-cooked spinach 8%.

Table 6.5.3-9: Residue levels of Cypermethrin in the treated Chinese cabbage and spinach specimens

Matrix	Concentration level	Application rate (kg as/ha)	Residue concentration (mg/kg)
Chinese Cabbage	Low	0.24	0.176
Chinese Cabbage	High	0.3	0.195*
Spinach	Low	0.13	1.32
Spinach	High	0.17	2.61*

*) Samples having residues nearer to legal Korea MRLs (5.0 mg/kg for Chinese cabbage and 2.0 mg/kg for spinach) were subjected to cooking test

Table 6.5.3-10: Residue and transfer ratios of Cypermethrin in processed fractions of Chinese cabbage and Spinach

Processed Fraction	Residue concentration (mg/kg)	Residue and transfer ratio (%)
Chinese cabbage - brining and washing		
Raw cabbage	0.20	100
Brined cabbage		112
Soaking brine		10
Washing after brining		7
Loss in brining		0

13*	0	6.5	13	8	10.5

*according to the report
Data are % of residues which are discarded in cooking process, out of total in the raw materials. Edible and inedible portions were regarded as follows. An edible portion in brining of Chinese cabbage is brined cabbage; its inedible portions are soaking brine, washings after brining and loss in brining. Edible portions in cooking of Chinese cabbage are cooked cabbage and cooking water; its inedible portion is loss in cooking. An edible portion in blanching of spinach is blanched spinach; its inedible portions are blanching water and loss in blanching. Edible portions in cooking of spinach are cooked spinach and cooking water; its inedible portion is loss in cooking. Residues in edible and inedible portinos were regarded as 100%.

III. CONCLUSION

The reduction of cypermethrin residues in the brined Chinese cabbage was 13% and in the heat-cooked Chinese cabbage 0%. The reduction of cypermethrin residues in the blanched spinach was 13% and in the heat-cooked spinach 8%.

The RMS and co-RMS consider the loss – values in Table 6.5.3-10 as erroneous/misleading and as insufficiently reliable. Therefore, Table 6.5.3-11 was to be removed in the RAR.

CA 6.6 Residues in Rotational Crops

CA 6.6.1 Metabolism in rotational crops

Residues in succeeding or rotational crops have been investigated for cypermethrin. Sufficient information regarding the metabolites found in soil has been generated from a confined ([^{14}C] radiolabeled) and non-radiolabeled crop rotational studies conducted with cypermethrin, aerobic soil metabolism studies conducted with alpha-cypermethrin and cypermethrin, and from alpha-cypermethrin photodegradation and cypermethrin anaerobic soil metabolism studies.

The fate of alpha-cypermethrin and cypermethrin in soil (aerobic soil metabolism) has been well defined and described in the dossiers submitted in 1995 by American Cyanamid Company for EU reregistration of these active substances. The data related to fate and behavior of alpha-cypermethrin and cypermethrin were presented together in Annex B of the alpha-cypemethrin monograph (September 1999) since several studies were presented in parallel for both active substances. This allowed extrapolation of the effects of one active substance to another.
Based on these studies and the fact that cypermethrin and alpha-cypermethrin behave similarly, succeeding crops in an alpha-cypermethrin treated field soil would be exposed mainly to the unchanged alpha-cypermethrin and to a much lesser extent to their soil and photo degradates, 3-phenoxybenzoic acid (3PBA) and 3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid (DCVA).

A summary of a 1993 study of alpha-cypermethrin photodegradation on soil (Van Dyk *et al.*) is presented in Section B. 7.1.1.3, Soil photolysis (Annex IIA 7.1.1.1.2) of the alpha-cypermethrin monograph. [^{14}C-benzyl] alpha-cypermethrin was used in this GLP study. The results indicate that alpha-cypermethrin is subjected to photolysis with subsequent formation of the metabolites, phenoxybenzoic acid (17% after 30 days) and phenoxybenzyl alcohol (2.7% after 30 days), bound residue (13.3% after 30 days) and mineralization (6.2% after 30 days). DT_{50} of 31 days (irradiated samples) and 193 days (dark samples) were calculated based on first-order reaction kinetics.

A summary of the anaerobic degradation of cypermethrin in soil [Section B. 7.1.2 Anaerobic degradaton in soil (Annex IIA 7.1.1.1.2)] is provided in the alpha-cypermethrin monograph. The findings showed that the degradation of cypermethrin under water-logged conditions was almost as rapid as in aerobic soil conditions. However, under anaerobic conditions, much greater amounts (52-72%) of the 3-PBA metabolite were found to accumulate in the soil. No mineralization occurred in this study (Standen, 1976).

In a crop rotational study (Jackson C., 1978) conducted to demonstrate the metabolism of [^{14}C] labeled cypermethrin (BAS 311 I) residues in potatoes grown as a rotation crop to lettuce, test substance [^{14}C] cypermethrin was labeled on the benzyl and cyclopropyl rings. At the time of lettuce harvest, the soil contained a total residue of 0.18 mg/kg and 0.10 mg/kg respectively, for the benzyl and cyclopropyl labeled cypermethrin. Similar residues were present in the soil when the rotation crop (potato) was sown. The cypermethrin metabolites, 3PBA and DCVA, were found and their presence confirmed. The mature potatoes contained very low levels of residues in tubers (≤ 0.01 mg/kg total residue) and haulms (≤ 0.007 mg/kg total residue) and no residues were detected in most of the samples. According to the conclusions in the cypermethrin monograph (October 1999), "The residues present in the soil 15 months after treatment were strongly absorbed to the soil."

Furthermore, the soil and photo degradates of cypermethrin have occurred at low levels (or have not been detected) as cypermethrin parent (<0.01 mg/kg), 3PBA and its conjugate (<0.05 ppm) and DCVA and its conjugate (<0.05 ppm) in non-radiolabeled succeeding crop studies on sugar beets, wheat, and field beans (peer-reviewed in the framework of the original inclusion into Annex I according to Directive 91/414/EEC; see below CA 6.6.2).

Based on the results of the cypermethrin confined crop rotational studies (using [^{14}C]) and unlabeled cypermethrin), alpha-cypermethrin and cypermethrin aerobic soil metabolism studies, alpha-cypermethrin photodegradation study, and cypermethrin anaerobic soil metabolism study, we would not expect to find metabolites other than those already identified in these studies (namely 3-PBA and DCVA), when conducting a crop rotational study with alpha-cypermethrin. As the 3-PBA and DCVA metabolites have occurred at low levels, we propose that the residue definition for rotational crops should only be alpha-cypermethrin parent (BAS 310 I). Thus, a non-radiolabeled crop rotational field study will adequately define the alpha-cypermethrin exposure in rotational crops.

CA 6.6.2 Magnitude of residues in rotational crops

In the framework of the original inclusion into Annex I according to Directive 91/414/EEC studies on the magnitude of the residue in rotational crops were peer-reviewed (Monograph Alpha-cypermethrin, September 1999, and 3rd Addendum: Addendum Chapter B-7 (Residue data), January 2003). No new studies have been performed.

The characteristics of the crop rotation studies are summarised in Table 6.6.2-1.

Table 6.6.2-1: Summary of studies in rotational crops previously available

Crop group	Crop	Test substance	Application and sampling details				Year	DocID
			Method, F or G	Rate (kg a.s./ha)	Interval between application and planting	Harvest time

In the studies performed with cypermethrin (Ripcord ® 40 EC; Doc IDs CY-790-057 and AL-790-032), cypermethrin was applied at a rate of 0.5 kg a.s./ha pre-planting. No residues of cypermethrin above the LOQ (0.01 mg/kg; bean foliage: 0.02 mg/kg) were detected in sugar beet (root and foliage) or wheat (straw) after approximately 2 years or in field beans (beans and foliage) after approximately 16 months.
No residues of the metabolites 3-phenoxybenzoic acid and 3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid above the LOQ (0.05 mg/kg) were detected in sugar beet roots and wheat straw approximately 2 years after treatment of soil with 0.5 kg cypermethrin/ha.

The magnitude of alpha-cypermethrin residues in rotational crops was investigated in two studies performed in Southern Europe (Italy and Southern France) and Northern Europe (Northern France and the United Kingdom).
In the first study performed in Italy (AL-790-049), prior to seeding or planting of representative crops (lettuce, head cabbage, carrot and wheat), alpha-cypermethrin was applied to 2 plots of bare soil at a dose rate of 20 g a.s./ha, once and 3 times respectively with 7 days interval between each application.
Rotational crops were sampled at various intervals between final application and harvest. The different samples were extracted and partitioned with solvents and were analysed by GC-MS which was validated for each isomer pair (cis 1, cis 2, trans 3 and trans 4). The limit of quantitation of the analytical method was 0.01 mg/kg. No detectable cypermethrin isomer residues (cis-1, cis-2, trans-3, trans-4) were found above the validated method LOQ (0.01 mg/kg) in any untreated specimen or in any rotational crop planted in BAS 310 I-treated soil at any interval sampled.
These data showed that the rotation crops took up no alpha-cypermethrin from soil. The level of residues at harvest didn't exceed the LOQ of the analytical method for monitoring (0.01 mg/kg for each isomer).

The second study was performed in France (North and South) and the United Kingdom (DocID 2002/1011569, AL-790-048). Prior to seeding or planting of representative crops (lettuce, cabbage, carrot and wheat), bare soil was treated either once or twice with alpha-cypermethrin at a dose rate of 20 g a.s./ha. The first and the second applications were made 19 days and 12 days before seeding or planting respectively. No ageing period of the soil was performed.
Cabbage, lettuce, carrots and wheat were sampled at different growth stages. The different samples were extracted with successive solvents and partitioned with water and the levels of residues were determined using GLC with mass spectrometric detection (Limit of quantitation : 0.01 mg/kg). The residues were determined as cis 1, cis 2, trans 3 and trans 4 isomers of cypermethrin.

No detectable cypermethrin isomer residues (cis-1, cis-2, trans-3, trans-4) were found above the validated method LOQ (0.01 mg/kg) in any untreated specimen.
No detectable cypermethrin isomer residues (cis-1, cis-2, trans-3, trans-4) were found above the validated method LOQ (0.01 mg/kg) in any cabbage or wheat planted in alpha-cypermethrin-treated soil at any interval sampled.
With one exception, no detectable cypermethrin isomer residues (cis-1, cis-2, trans-3, trans-4) were found above the validated method LOQ (0.01 mg/kg) in any lettuce planted in BAS 310 I-treated soil at any interval sampled. A trace trans-4 (0.01 mg/kg) residue was detected in the immature lettuce (BBCH 16) in one trial 48 days following the second of two treatments at 20 g a.s./ha.

0.02 mg/kg trans-4 and 0.03 mg/kg trans-4 were found in two immature whole carrot plants (BBCH 16) in one trial (Southern France) 60 days following the 1 x 20 g a.s./ha and 2 x 20 g a.s./ha, respectively. There were no other detectable cypermethrin isomer residues (cis-1, cis-2, trans-3, trans-4) found above the validated method LOQ (0.01 mg/kg) in any remaining carrot specimens from the BAS 310 I-treated soil.
It was concluded that the rotation crops took up very little alpha-cypermethrin from the soil. The level of residues at harvest didn't exceed the LOQ of the analytical method for monitoring (0.01 mg/kg) No MRL was proposed for rotational crops.

Overall conclusion on the magnitude of residues in rotational crops

The data available from rotational crop studies show that residues of alpha-cypermethrin can be expected to be very low. In cabbage, carrot, lettuce and wheat planted on alpha-cypermethrin treated soil approximately two weeks after the final of 1-3 treatments at 20 g a.s./ha/treatment no residues of cypermethrin isomers (cis-1, cis-2, trans-3, trans-4) above the limit of quantitation (0.01 mg/kg) were found in the edible parts at harvest.

It was shown that the application of alpha-cypermethrin at a rate exceeding the critical GAP did not lead to a significant uptake in edible parts of vegetables with short development times even when planted after a short re-plant interval of approximately two weeks. This scenario can be regarded as worst case situation and it can therefore be concluded that after longer waiting periods or in plants with longer development times no residues of alpha-cypermethrin will be found.

CA 6.7 Proposed residue definitions and maximum residue levels

CA 6.7.1 Proposed residue definitions

Plant Matrices

For proposing a suitable residue definition in plant and animal matrices, multiple investigations were performed. As presented in sections 6.2, 6.3, 6.5 and 6.6, plant and animal studies were performed in which alpha-cypermethrin was applied according to the intended use patterns.

For deriving a suitable **residue definition for food of plant origin**, five crop metabolism studies in three different crop categories using ^{14}C-benzyl-, ^{14}C-vinyl- and/or ^{14}C-cyclopropane-labeled alpha-cypermethrin were performed covering the categories of leafy vegetables, brassica vegetables and cereals. The effect of processing on the nature of the residue was investigated in the framework of the original inclusion into Annex I according to Directive 91/414/EEC using test conditions simulating pasteurization, baking, brewing, boiling and sterilization. Information on the residue situation in succeeding or rotational crops is available from a confined ([^{14}C] radiolabeled) and non-radiolabeled crop rotational studies conducted with cypermethrin, aerobic soil metabolism studies conducted with alpha-cypermethrin and cypermethrin, and from alpha-cypermethrin photodegradation and cypermethrin anaerobic soil metabolism studies.

In general, metabolism of alpha-cypermethrin in plants comprises

-hydrolysis at the ester linkage with the formation of two moieties :
a) the phenoxybenzoyl portion which leads to a multiplicity of metabolites as acids, aldehydes, alcohols and converted into amino acids or glucose conjugates;
b) the dichlorovinyl cyclopropane acid portion of the molecule (cis- and trans-DCVA isomers and conjugates)

-oxidative ring hydroxylation of the phenyl ring which was observed only in wheat and cabbage.

The metabolism studies indicate that parent alpha-cypermethrin is usually the predominant component. Slight isomeric conversion from cis to trans configuration was observed in wheat forage, hay and straw.
Alpha-cypermethrin was found to be susceptible to hydrolysis at the ester linkage at simulated processing conditions at pH 6 at 120°C resulting in the breakdown of the ester linkage to 3-phenoxybenzaldehyde (M310I018, CL 206969) and dichlorovinydimethylcarboxylic acid (DCVA, M310I001, CL 912554) which are also found in the metabolism studies (see CA 6.5.1). Formation of 3-Phenoxybenzaldehyde (M310I018) was also reported in a published study (Lin *et al.*, 2005/1043620, see CA 6.5.1/1)

It was shown that the application of alpha-cypermethrin at a rate exceeding the critical GAP did not lead to a significant uptake in edible parts of vegetables with short development times even when planted after a short re-plant interval of approximately two weeks. This scenario can be regarded as worst case situation and it can therefore be concluded that after longer waiting periods or in plants with longer development times no residues of alpha-cypermethrin will be found.

Based on these findings from all studies summarised above the following residue definitions for alpha-cypermethrin in plant matrices are proposed:

For dietary risk assessment: alpha-cypermethrin

For MRL setting alpha-cypermethrin

Animal matrices

The main biotransformation reactions were observed in rats, goats and laying hens, so there is a consistent picture of the metabolism of ^{14}C-BAS 310 I in all animal species investigated.

Ensuing from the degradation routes as explained for plant metabolism, cleavage of the ester linkage, loss of the nitrile group and oxidation is observed with the formation of two moieties, the phenoxybenzoyl portion and the dichlorovinyl cyclopropane acid portion of the molecule. Hydroxylation and / or conjugation occur with both parts of the molecule.

The metabolism studies indicate that parent alpha-cypermethrin is usually the predominant component.

In order to analyze whether one isomer of alpha-cypermethrin was preferably metabolized, enantiomer-specific analysis of the parent compound BAS 310 I, isolated from selected matrices, was performed in goat and hen. In goats for both labels, matrix-specific differences were observed for the isomer ratio. While in feces the ratio of both isomers of BAS 310 I was found to be approximately 1:1 for both labels, the relative amount of the (S)-cyano-(1R,3R) (isomer 1) was lower compared to the (R)-cyano-(1S,3S) (isomer 2) in the other investigated matrices (milk and renal fat in the case of the benzyl label, milk, composite fat and composite muscle in the case of the cyclopropane label). The relative amounts of isomer 1 : isomer 2 ranged from values of 16.0% : 84.0% to 22.2% : 77.8%. In hens the parent compound BAS 310 I was also isolated from egg yolk and fat extracts in order to determine the enantiomer ratio. For both labels, the enantiomer ratio of BAS 310 I in egg yolk and fat was approximately 1:1, similar to the ratio of the application solutions.
Based on these findings from all studies summarised above the following residue definitions for alpha-cypermethrin in animal matrices are proposed:

For risk assessment

in milk and kidney: alpha-cypermethrin

in other animal matrices: alpha-cypermethrin

For enforcement alpha-cypermethrin

Metabolites

In order to address the relevance of the main plant and animal metabolites, the approach as laid down in the Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment, (EFSA Journal 2012;10(07): 2799) was mainly followed.
For the all metabolites identified in the metabolism studies cited in this dossier the exposure assessment showed that the Cramer class III trigger of 1.5 µg/kg bw/day was not exceeded (see MCA, chapter 6.9). Therefore, these metabolites were not included into the residue definition for risk assessment.

CA 6.7.2 Proposed maximum residue levels (MRLs) and justification of the acceptability of the levels proposed

Table 6.7.2-1 shows the existing EU MRLs as well as the MRLs proposed in this dossier:

Table 6.7.2-1: Existing and proposed MRLs for alpha-cypermethrin

Code Number	Commodity	Existing EU MRL (mg/kg)	New proposals by BASF (mg/kg)
Enforcement residue definition:		**Cypermethrin (sum of all constituent isomers)**	**Alpha-cypermethrin**
232010	Cucumber	0.2	~~0.06~~ 0.05
232030	Courgette	0.2	~~0.06~~ 0.05
243010	Chinese cabbage	1	~~1.5~~ 1.0
243020	Kale	1	~~1.5~~ 1.0
251020	Lettuce	2	1.0

500090	Wheat	2	0.015

a indicates the lower limit of analytical determination

MRLs in this dossier are based on residue trials as described in chapter CA 6.3 with application rates according to the current cGAPs. MRLs are proposed based on the rounded MRLs of parent alpha-cypermethrin derived with the OECD calculator (OECD calculator spreadsheet: http://www.oecd.org/document/34/0,3746,en_2649_37465_48447010_1_1_1_37465,00.html).

Cucumber / Courgette

For cucumber 16 indoor trials are available which were performed according to the cGAP for courgette (2 indoor applications at 0.015 kg/ha, PHI 3 days for EU South or a single indoor application at 0.03 kg/ha, PHI 3 days for EU North, Central and South). The trials are described in chapter CA 6.3.1. As the residue trials in cucumbers support the critical GAP for courgette, according to European Community Guideline 7525/VI/95 rev. 9 dated March 2011 extrapolation from cucumber to courgette is adequate. The MRL calculations are based on the results of the study reported in DocID 2006/1036934 which represents the worst-case scenario (a single application at a target rate of 0.04 kg a.s./ha, target PHI 3±1 days; 8 trials). Despite the application rate deviating more than +25% from the cGAP rate, the 8 independent trials at 0.04 kg a.s./ha, are considered acceptable to support the critical GAP. Additionally, applying the proportionality concept to the dataset allowed to derive STMR and HR values and to calculate an additional MRL closer to realistic conditions.

DocID	Residues at target PHI (mg/kg)	Residues at target PHI (mg/kg) applying proportionality concept (x 0.75)	Region
2006/1036934	<0.01 (2x), 0.012, 0.014 (2x), 0.02, 0.031, 0.037	<0.01 (2x), 0.009, 0.011 (2x), 0.015, 0.023, 0.028	Europe (indoor)

Table 6.7.2-2: MRL calculation for cucumber

OECD Calculator	Alpha-cypermethrin [mg/kg]	Alpha-cypermethrin [mg/kg] applying proportionality concept
	EU, indoor	EU, indoor
Highest residue	0.037	0.028
Mean + 4 SD	0.059	0.043
CF x 3 Mean	0.046	0.037
Rounded MRL	**0.06**	**0.05**
STMR	0.014	0.011

Based on these calculations the following EU MRL is proposed according to the residue definition for enforcement (alpha-cypermethrin) and the present residue data reflecting the worst-case scenario:

0.06 mg/kg for courgettes (group 232030).

Leafy brassica

For leafy brassica 12 outdoor trials are available which were performed according to the cGAP (2 outdoor application at 0.01 kg/ha with a PHI of 3 days in Northern, Central and Southern Europe or a single outdoor application at 0.02 kg/ha with a PHI of 3 days in Southern Europe). 4 of these trials were done in EU North; in EU South, 8 trials were conducted. The trials are described in chapter CA 6.3.2. The MRL calculations are based on the results of the studies reported in DocIDs 2006/1026862, 2007/1013342 and 2013/1416285, which represent the worst-case scenario (two applications at a target rate of 0.0125 kg/ha (N-EU and S-EU) or a single application at 0.025 kg a.s./ha (S-EU), target PHI 3±1 days). At a few occasions, a higher residue level was measured at a later PHI and in other cases, at a certain PHI a higher residue level was observed after the single treatment than after the double treatment. These more critical residue values were considered for MRL calculation purposes. Despite the application rate deviating more than +25% from the cGAP rate, the independent trials at (1)-2x 0.0125 kg a.s./ha, are considered acceptable to support the critical GAP. Additionally, applying the proportionality concept to the dataset allowed to derive STMR and HR values and to calculate an additional MRL closer to realistic conditions.

STMR	0.290	0.060	0.134

*High uncertainty of MRL estimate due to small dataset

Based on the worst-case scenario calculations an EU MRL of

1.5 mg/kg for leafy brassica (group 243000)

is proposed according to the residue definition for enforcement (alpha-cypermethrin) and the present residue data.

Lettuce

For lettuce 29 outdoor trials are available which were performed according to the cGAP (2 appl. at 0.01 kg/ha with a PHI of 3 days in Northern, Central and Southern Europe or a single application at 0.02 kg/ha with a PHI of 3 days in Southern Europe, outdoor). 10 of these trials were done in EU North; in EU South, 19 trials were conducted. The trials that have not been peer-reviewed are described in chapter CA 6.3.3. One trial is considered that had already been peer-reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 (AL-726-004).

The MRL calculations are based on the results of the studies reported in DocIDs AL-726-004, 2006/1026855, 2007/1008496, 2007/1007938 and 2014/1140312, which represent the worst-case scenario (two applications at a target rate of 0.0125 kg/ha (N-EU and S-EU) or a single application at 0.025 kg a.s./ha (S-EU), target PHI 3±1 days; one application at 0.015 kg a.s./ha with a PHI of 3 days in study AL-726-004).

DocID	Residues at target PHI (mg/kg)	Region

Rounded MRL	**1.0**	**0.9**	**0.9**
STMR	0.123	0.195	0.125

Based on these calculations an EU MRL of

1.0 mg/kg for lettuce and salad plants (group 0251000)

is proposed according to the residue definition for enforcement (alpha-cypermethrin) and the present residue data.

Oilseed rape

For oilseed rape 29 trials were considered. 13 of these trials were done outdoor in EU North; in EU South, 16 outdoor trials were conducted. The trials that have not been peer-reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 are described in chapter CA 6.3.4.

The MRL calculations are based on the results of the studies reported in DocIDs 2008/1019999, 2013/1037957 and 2013/1416283, which represent the worst-case scenario (two applications at a target rate of 0.0105 kg/ha (N-EU and S-EU), target PHI 28±1 days). 11 trials that had already been peer-reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 were also considered (AL-750-004 – one treatment at 0.02 kg a.s./ha, AL-750-021 - one treatment at 0.02 kg a.s./ha, and 2002/1004087 – 2 treatments at 0.01 kg a.s./ha).

DocID	Residues at target PHI (mg/kg)	Region

STMR	0.01	0.01	0.01

* High uncertainty of MRL estimate due to high level of censoring.

Based on these calculations an EU MRL of

0.08 mg/kg for oilseed rape seed (group 401060)

is proposed according to the residue definition for enforcement (alpha-cypermethrin) and the present residue data.

Barley

For barley 17 trials trials were considered. 8 of these trials were done in EU North; in EU South, 9 trials were conducted. The trials that have not been peer-reviewed within the framework of inclusion of alpha-cypermethrin into Annex I of Directive 91/414 are described in chapter CA 6.3.5. One trial is considered that had already been peer-reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 (AL-730-029).
The MRL calculations are based on the results of the studies reported in DocIDs 2013/1388974, 2013/1416281, 2013/1416284 and 2014/1173599 which represent the worst-case scenario (two applications at a target rate of 0.0125 kg/ha (N-EU and S-EU), target PHI of 28±1 days (or BBCH 89). One trial that had already been peer-reviewed was also considered - one application at 0.015 kg a.s./ha in study AL-730-029).

Rounded MRL	**0.15**	**0.15**	**0.15**
STMR	0.033	0.035	0.035

Based on these calculations an EU MRL of

0.15 mg/kg for barley grain (group 500010)
0.15 mg/kg for oats grain (group 500050, by extrapolation from barley according to SANCO 7525/VI/95 - rev.9, March 2011)

is proposed according to the residue definition for enforcement (alpha-cypermethrin) and the present residue data.

Wheat

For wheat 35 trials are available which were performed according to the cGAP (2 appl. at 0.01 kg/ha with a PHI of 28 days in Northern, Central and Southern Europe, outdoor). 16 of these trials were done in EU North; in EU South, 19 trials were conducted. The trials that have not been peer-reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 are described in chapter CA 6.3.6. 15 trials are considered that had already been peer-reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414 (AL-730-001, AL-730-003, AL-730-029, AL-730-030, AL-730-031).
The MRL calculations are based on the results of the studies reported in DocIDs 2008/1002701, 2013/1416282, and 2014/1028112, which represent the worst-case scenario (two applications at a target rate of 0.0125 kg/ha (N-EU and S-EU), target PHI of 28±1 days (or BBCH 89). 15 trials are considered that had already been peer-reviewed – one treatment at 0.015-0.0175 kg a.s./ha (AL-730-001, AL-730-003, AL-730-029, AL-730-030, AL-730-031).

*High uncertainty of MRL estimate due to high level of censoring

Based on these calculations an EU MRL of

0.015 mg/kg for wheat (spelt, triticale, group 500090)
0.015 mg/kg for rye (group 500070, by extrapolation from wheat according to SANCO 7525/VI/95 - rev.9, March 2011)

is proposed according to the residue definition for enforcement (alpha-cypermethrin) and the present residue data.

Animal matrices

Feed burden calculations

Intended uses with the representative formulation BAS 310 55 I covered in this submission include the crops leafy brassica, oilseed rape and cereals (barley and wheat). These crops are relevant as feed items.

In this submission, also a risk assessment describing the uses intended by BASF in future is enclosed to provide a realistic overview beyond the representative uses. Therefore, also a new feed burden calculation based on these data is necessary.

The input values used for this calculation are summarized in Table 6.7.2-8. Detailed information on the studies and the individual residue values used for the estimation of the livestock feed burden is given in the supplement dossier.

The targeted crop treatment timing is actually excluding the timing for forage production of cereal crops (except barley). However, the current GAPs do not explicitly exclude cereal cultivation for fodder /hay/silage production, which would manly concern barley, if at all. However, the extrapolation to other cereals does reflect a worst-case situation and is therefore applied here.

7 calculated using STMR of potatoes (0.01 mg/kg) x median TF (3.285) from raisin production as estimate for residue concentration during drying (DocID 2005/1014175, see supplement dossier)
8 calculated using STMR of tomatoes (0.037 mg/kg, glasshouse)) x median TF (6.3) from remainder of straining from tomato juice processing as estimate for residue concentration in tomato pomace (DocID 2006/1021295, see supplement dossier)

Feed commodities related to representative uses are underlined

The feed burden calculations for Europe were performed using the OECD calculator.
Two scenarios were calculated using the data listed in Table 6.7.2-8: Scenario 1 considering only the representative uses and scenario 2 considering all uses to be defended in future.

Scenario 1:
A summary is given in Table 6.7.2-9 and Table 6.7.2-10. In Table 6.7.2-11 and Table 6.7.2-12 the results of the total maximum and mean dietary burden calculations for cattle (beef and dairy), sheep (ram/ewe and lamb), swine (breeding and finishing) and poultry (broiler, layer, turkey) for the European Union (EU) are presented in detail.

Table 6.7.2-9: Summary: Maximum Feed burden calculation results for Europe (Reasonable Worst Case Feeding Levels (RWCFL)) – Scenario 1, only representative uses considered

Scenario 2:

A summary is given in Table 6.7.2-13 and Table 6.7.2-14. In Table 6.7.2-15 and Table 6.7.2-16 the results of the total maximum and mean dietary burden calculations for cattle (beef and dairy), sheep (ram/ewe and lamb), swine (breeding and finishing) and poultry (broiler, layer, turkey) for the European Union (EU) are presented in detail.

Table 6.7.2-13: Summary: Maximum Feed burden calculation results for Europe (Reasonable Worst Case Feeding Levels (RWCFL)) – Scenario 2, all uses considered

Below it is shown which residues are to be expected in animal matrices based on the results of the feeding studies (see CA 6.4) as well as the estimation of the livestock dietary burden as shown above. All calculated livestock dietary burdens are below the lowest dose levels applied in the feeding studies. Therefore, the estimation of the expected residues in animal commodities is based on the residues found in the lowest dose groups.

Expected residues based on scenario 1 (representative uses only) are given in table Table 6.7.2-17, residues based on scenario 2 (all uses) are summarized in Table 6.7.2-18.

The results clearly show that the expected alpha-cypermethrin residues in animal matrices are well below the residue levels found in the feeding studies in the lowest dose groups for all scenarios assessed.

Table 6.7.2-17: Expected residues in animal matrices: Scenario 1, representative uses only

Milk	3.9	0.14	<0.01	0.813	0.031	0.521	0.012	0.002	0.001
Poultry egg	1.6[3]	0.0987	<0.01	0.432	0.030	0.170	0.012	0.003	0.001

1 expected residues were calculated by applying the transfer factor (residue level in milk, eggs or tissue / residue level in diet) at the lowest feeding level to the dietary burden. For sheep and swine tissues, results from the cow feeding study were applied.
2 dose level calculated based on a daily dose (capsule dosing)) of 77 mg alpha-cypermethrin per animal with an estimated weight of 550 kg; dietary equivalent is based on a theoretical consumption of 20 kg dry material/animal/day
3 actual feed level
4 tissue samples from lower dose groups were not analysed because no residues above the LOQ were detected in tissue samples from the highest dose group. For calculation of expected residues the dietary burden of the lowest dose group (1.6 mg/kg DM) was used.

Table 6.7.2-18: Expected residues in animal matrices: Scenario 2, all uses

Poultry egg	1.6[3]	0.0987	<0.01	0.432	0.030	0.170	0.012	0.003	0.001

1 expected residues were calculated by applying the transfer factor (residue level in milk, eggs or tissue / residue level in diet) at the lowest feeding level to the dietary burden. For sheep and swine tissues, results from the cow feeding study were applied
2 dose level calculated based on a daily dose (capsule dosing)) of 77 mg alpha-cypermethrin per animal with an estimated weight of 550 kg; dietary equivalent is based on a theoretical consumption of 20 kg dry material/animal/day
3 actual feed level
4 tissue samples from lower dose groups were not analysed because no residues above the LOQ were detected in tissue samples from the highest dose group. For calculation of expected residues the dietary burden of the lowest dose group (1.2 mg/kg DM) was used.

Fish feed burden calculation

A fish feed burden calculation for alpha-cypermethrin based on the critical GAPs of the representative uses and all uses to be defended in future (Scenario 2) was performed using the DietaryBurdenCalculator 1.0.4 (Fraunhofer IME Schmallenberg, Germany). The model was used for carp and rainbow trout, considering the maximum reasonable balanced diet, as well as compositions by adding untreated carborhydrate concentrate, protein concentrate and fat in every combination possible.

The input values used for this calculation are summarized in the table below. Detailed information on the studies and the individual residue values used for the estimation of the livestock feed burden is given in the supplement dossier.

Table 6.7.2-19: Residue values used for calculation of the fish feed burden, Scenario 2

Crop	IFN Code	Residue value type	Residue input value (mg/kg)
Barley bran fractions	4-00-515	STMR-P	0.203[1]
Brewer's grain	5-00-516	STMR-P	0.033[2]
Cottonseed meal	5-01-617	STMR	0.01
Distiller's grain	5-00-518	STMR	0.033[2]
Linseed meal	5-02-048	STMR	0.01
Rape seed meal	5-26-093	STMR	0.01
Canola meal	5-08-136	STMR	0.01
Safflower meal	5-26-095	STMR	0.01
Corn grain	4-20-698	STMR	0.01
Cow pea seed	5-01-661	STMR	0.01
Faba bean seed		STMR	0.01
Lupin seed	5-02-707	STMR	0.01
Pea seed	5-03-600	STMR	0.01
Rice broken grains	4-03-939	STMR	0.092
Wheat grain	4-05-211	STMR	0.01

1 calculated using STMR of barley grain (0.035 mg/kg) x median TF (5.79) of pearling dust/bran from barley processing study 2007/1013068 (see MCA 6.5)

2 calculated using STMR of barley grain (0.035 mg/kg) x median TF (0.95) of spent grain from barley processing studies AL-730-061 and 2007/1013068 (see MCA 6.5)

The results presented in Table 6.7.2-20 below show that the expected alpha-cypermethrin residues in fish feed are well below the lowest dose level of 10 mg/kg administered to rainbow trout (see study CA 6.2.5/1).

Table 6.7.2-20: Summary: Fish feed burden calculation, Scenario 2

	Maximum residue burden in fish feed (mg/kg)	
	Common carp	**Rainbow trout**
Without additions	0.048	-
Without additions (MRBD)	-	-
Adding of PC	0.079	0.078
Adding of PC (MRBD)	0.079	0.055
Adding of CC	0.048	-
Adding of CC (MRBD)	-	-
Adding of fat/oil	0.048	-
Adding of fat/oil (MRBD)	-	-
Adding of PC and CC	0.079	0.078

Adding of PC and fat/oil	0.079	0.078
Adding of PC and fat/oil (MRBD)	0.079	0.056
Adding of CC and fat/oil	0.048	-
Adding of CC and fat/oil (MRBD)	-	-
Adding of PC, CC and fat/oil	0.079	0.078
Adding of PC, CC and fat/oil (MRBD)	0.079	0.056
Worst case feed burden	**0.079**	**0.078**

MRBD maximum reasonable balanced diet
PC protein concentrate (fish meal)
CC carbohydrate concentrate (starch)

In Table 6.7.2-21 it is shown which residues are to be expected in fish matrices based on the results of the fish metabolism study conducted (see CA 6.2.5) as well as the estimation of the fish dietary burden as shown above. The feed burden is well below the lowest dose levels applied in the metabolism study. Therefore, the expected residues are estimated based on the 10 mg/kg dose group by multiplying with a transfer factor (0.0079). The results are given in Table 6.7.2-21.

The results clearly show that the expected alpha-cypermethrin residues in fish matrices are below the limit of quantitation.

Table 6.7.2-21: Expected residues in fish matrices: Scenario 2

Matrix	Metabolite	[Benzyl-U-^{14}C]-BAS 310 (mg/kg)		[Cyclopropane-^{14}C]-BAS 310 I (mg/kg)	
		Residue at 10 mg/kg*	Maximum residue expected**	Residue at 10 mg/kg	Maximum residue expected**
Composite muscle	BAS 310 I	0.071	0.000561	0.060	0.000474

CA 6.7.3 Proposed maximum residue levels (MRLs) and justification of the acceptability of the levels proposed for imported products (import tolerance)

Plant Products

According to the proposed residue definition for MRL setting of

Alpha-cypermethrin parent

and referring to MRL derivations in chapter CA 6.7.2 it is proposed to establish EU MRLs of:

0.06 mg/kg for courgettes (group 232030)
0.08 mg/kg for oilseed rape seed (group 401060)
0.15 mg/kg for barley grain (group 500010)
0.15 mg/kg for oats grain (group 500050)
0.015 mg/kg for wheat (spelt, triticale) grain (group 500090)
0.015 mg/kg for rye grain (group 500070)

Animal products

According to the proposed residue definition for MRL setting of

Alpha-cypermethrin parent

and referring to MRL derivations in chapter CA 6.7.2 it is proposed to establish EU MRLs of:

0.05 mg/kg for ruminant and pig meat, liver and kidney
0.1 mg/kg for ruminant fat
0.05 mg/kg for pig fat
0.01 mg/kg for milk
0.01 mg/kg for eggs

CA 6.8 Proposed safety intervals

Residue trials have been conducted with applications made at the latest recommended crop growth stage with harvest taking place at the time of crop maturity following good agricultural practice.

Pre-harvest interval
In cucumber / courgette application at the growth stage BBCH 10-89 with the pre-harvest interval of 3 days (indoor) is intended. For leafy ~~cabbages~~ brassica application is possible during growth stage BBCH 10-49 with pre-harvest intervals of 3 days (outdoor). For lettuce application at the growth stage BBCH 10-49 with the pre-harvest interval of 3 days (outdoor) is intended.
For oilseed rape application is possible during growth stage BBCH 51-59 with the pre-harvest interval of 28 days (outdoor). For cereals application at the growth stage BBCH 51-83 with the pre-harvest interval of 28 days (outdoor) is intended.

Re-entry period for livestock to areas to be grazed
Because alpha-cypermethrin is not intended to be used in areas to be grazed, no re-entry period for livestock has to be defined.

Re-entry period for man to treated crops
Re-entry assessments are given for the representative uses in the supplemental product dossiers (M-CP 7.2). Re-entry is possible after the spray deposits on the crops have dried given the worker is wearing adequate work clothing.

Witholding period for animal feed stuffs
Treated cereals, oil seed rape and leafy ~~cabbage~~ brassica feed items may be used as fodder for livestock. Alpha-cypermethrin derived residues in those feed items are assessed in M-CA 6.7 by providing updated calculations of livestock dietary burdens and deriving suitable MRLs for animal products covering the intended uses. There is no additional withholding period needed for animal feeds with regard to alpha-cypermerthrin derived residues in feed items.

Waiting period between application and crop sowing or planting the crop to be protected
No waiting period is necessary since alpha-cypermethrin is not intended in pre-emergence use.

Waiting period between application and handling treated produce
This is not relevant here since a post-harvest treatment is not intended for cucumber / courgette, leafy cabbage, lettuce, oilseed rape and cereals.

Waiting period between last application and sowing or planting succeeding crops
No replant restrictions are needed; no detectable (0.01 mg/kg) residues of BAS 310 I (cis-2 isomer of cypermethrin) or any of the three other cypermethrin isomers (cis-1, trans-3, or trans-4) are expected in succeeding crops when BAS 310 I is applied at the proposed GAP. Refer to succeeding crop studies (Alphacypermethrin EU Dossier, Document M-II/Addendum, Section 6.6, 2002).

CA 6.9 Estimation of the potential and actual exposure through diet and other sources

Assessments of the potential chronic and acute dietary consumer risk due to exposure to residues of alpha-cypermethrin were performed using the EFSA model for chronic and acute risk assessment - rev. 2_0 (Model PRIMo). The EFSA model was used since it considers all the different diets in the EU and all consumer groups.
The ADI and ARfD for the active substance alpha-cypermethrin are summarized in the table below.

Table 6.9-1: Toxicological endpoints – alpha-cypermethrin

Endpoint	Value	Study	Safety factor	Reference
Acceptable Daily Intake (ADI)	0.02 mg/kg bw/d	1-year study in dogs	100	EFSA Review Report (2004), SANCO/4335/2000
Acute Reference Dose (ARfD)	0.04 mg/kg bw/d	Acute neurotoxicity study in rats	100	EFSA Review Report (2004), SANCO/4335/2000

CA 6.9.1 Acceptable Daily Intake (ADI) and Dietary Exposure Calculation

TMDI calculation

The calculation of the TMDI was performed for the representative crops cucumber / courgette, leafy brassica, oilseed rape, barley and wheat using the maximum residue levels summarised in Table 6.9.1-1. These MRLs were calculated in section M-CA 6.7 based on the residues data from section M-CA 6.3. For lettuce, oilseed rape, barley and wheat residue trials have been considered for the MRL calculations that had already been peer reviewed within the framework of the original inclusion of alpha-cypermethrin into Annex I of Directive 91/414, as described in Section M-CA 6.7. For the reviewer´s convenience, these data are summarized in the supplement information document (DocID 2014/1314800).
Beyond that, in the risk assessment also calculated MRLs, highest residues (HRs) and STMRs of residue values for crops were considered as a second scenario, which are on the one hand not foreseen in context of this submission, but are on the other hand relevant for BASF and chronic dietary risk assessment. All those residue studies were conducted according to long-term GAPs with a reduced number of applications, compared to GAPs being valid some years ago.
Calculated MRLs, HRs and STMRs are summarized in Table 6.9.1-1. Summaries of the individual studies are included as supplemental information document (DocID 2014/1314800) to this dossier. The supplement information document also includes an Appendix where all individual residue data are tabulated with their corresponding DocID, trial number and the PHI.

For animal matrices, the livestock dietary burden calculations showed that the estimated dietary burden is well below the lowest feeding level applied in the ruminant and poultry feeding studies (see M-CA 6.7). Therefore, the residue levels used to calculate the ADI contribution from animal matrices are based on the residues found in the feeding studies at the lowest dose levels.

Data for representative uses underlined in bold
1) calculation based on outdoor use

Based on the input values as shown in the above table the following results for the chronic risk assessments are obtained:

Scenario 1 shows that considering only the representative uses as submitted in this dossier would lead to an utilisation of the ADI of 0.1 to 4.6 %. The diet with the highest TMDI is "NL child" with 4.6% of ADI. For this diet, the highest contributor is cattle milk with 1.5% of ADI. The diet with the second highest TMDI is “ES child” “with 4.2% of ADI where lettuce is the major contributor (2.1% of ADI).

Scenario 2 shows the chronic risk assessment including those crops which are to be defended in future. The ADI of 0.02 mg/kg bw/d is utilised to 1.5-49.1%. The diet with the highest TMDI is "UK toddler" with 49.1 % of ADI. For this diet, the highest contributor is sugar beet root with 45.7% of ADI. The diet with the second highest TMDI is “UK infant” with 23.2% of ADI where also sugar beet (root) is the major contributor (20.2 % of ADI).

Table 6.9.1-2: Results of chronic risk assessments

Input values	Highest exposure	
	% of ADI	Diet
Residue definition for risk assessment:	alpha-cypermethrin	
ADI:	0.02 mg/kg bw/d	
Scenario 1: Representative uses only	4.6%	NL child
Scenario 2: all crops to be defended in future	49.1%	UK toddler

According to the presented TMDI calculations a long-term intake of alpha-cypermethrin residues is unlikely to present a public health concern, even when the worst case situation is considered.

NEDI calculation

For all population groups included in the EFSA model, the use of STMR or STMRP values in the estimation of the chronic dietary consumer risk is up to this point in time not necessary since the crude overestimated TMDI of alpha-cypermethrin was well below 100% of the ADI for the representative uses courgette, kale, lettuce and cereals as well as under consideration of the contribution of all uses.

NESTI calculations

The acute dietary risk assessment was performed according to the EFSA PRIMo model, applying the calculated MRLs for the representative uses shown in Table 6.9.1-1.

An acute Reference Dose (ARfD) of 0.04 mg/kg bw was used. The results of the IESTI calculations are summarised below and in Table 6.9.1-5.

Conclusion:
The estimated Theoretical Maximum Daily Intakes (TMDI), based on pTMRLs were below the ADI.
A long-term intake of residues of Alpha-cypermethrin is unlikely to present a public health concern.

The commodity which had the highest calculated IESTI 1 or IESTI 2 is listed on top of this section, respectively. If IESTI is more than 90% of the ARfD/ADI, the results are reported in this sheet. However, at least the top 5 commodities are reported, even if the IESTI is lower than 90%.

The acute risk assessment showed no exceedance of the ARfD for adults for both IESTI calculations.

For children, the ARfD is exceeded for the following unprocessed commodities:

	Member State	IESTI 1 (%)	IESTI 2 (%)
Kale	NL	253.5	181.1

For processed commodities, no exceedance of the ARfD was identified.

As a refinement, the HR (0.59 mg/kg) was used instead of the MRL for calculation of the acute dietary risk assessment for kale. No exceedance of the ARfD was identified after the refinement.

Table 6.9.1-5: IESTI calculation for the representative uses – MRLs applied

Acute risk assessment /children						Acute risk assessment / adults / general population					
The acute risk assessment is based on the ARfD.											
For each commodity the calculation is based on the highest reported MS consumption per kg bw and the corresponding unit weight from the MS with the critical consumption. If no data on the unit weight was available from that MS an average European unit weight was used for the IESTI calculation.											
In the **IESTI 1** calculation, the variability factors were 10, 7 or 5 (according to JMPR manual 2002), for lettuce a variability factor of 5 was used. In the **IESTI 2** calculations, the variability factors of 10 and 7 were replaced by 5. For lettuce the calculation was performed with a variabilty factor of 3.											
Threshold MRL is the calculated residue level which would leads to an exposure equivalent to 100 % of the ARfD.											
Unprocessed commodities	**No of commodities for which ARfD/ADI is exceeded (IESTI 1):**	1	**No of commodities for which ARfD/ADI is exceeded (IESTI 2):**	1		**No of commodities for which ARfD/ADI is exceeded (IESTI 1):**	---	**No of commodities for which ARfD/ADI is exceeded (IESTI 2):**	---

	0,4	Wheat flour	0,015 / -				0,2	Bread/pizza	0,015 / -			
*) The results of the IESTI calculations are reported for at least 5 commodities. If the ARfD is exceeded for more than 5 commodities, all IESTI values > 90% of ARfD are reported.												
**) pTMRL: provisional temporary MRL												
***) pTMRL: provisional temporary MRL for unprocessed commodity												
Conclusion:												
For Alpha-cypermethrin IESTI 1 and IESTI 2 were calculated for food commodities for which pTMRLs were submitted and for which consumption data are available.												
The estimated short term intake (IESTI 1) exceeded the ARfD/ADI for 1 commodities.												
Also the IESTI 2 calculation, using less conservative variability factors, resulted in exceedances of the ARfD/ADI for 1 commodities.												
For processed commodities, no exceedance of the ARfD/ADI was identified.												

Table 6.9.1-6: IESTI calculation for the representative uses – refinement applying HR for kale

Acute risk assessment /children - refined calculations						Acute risk assessment / adults / general population - refined calculations					
The acute risk assessment is based on the ARfD.											
For each commodity the calculation is based on the highest reported MS consumption per kg bw and the corresponding unit weight from the MS with the critical consumption. If no data on the unit weight was available from that MS an average European unit weight was used for the IESTI calculation.											
In the **IESTI 1** calculation, the variability factors were 10, 7 or 5 (according to JMPR manual 2002), for lettuce a variability factor of 5 was used. In the **IESTI 2** calculations, the variability factors of 10 and 7 were replaced by 5. For lettuce the calculation was performed with a variabilty factor of 3.											
Threshold MRL is the calculated residue level which would leads to an exposure equivalent to 100 % of the ARfD.											
Unprocessed commodities	**No of commodities for which ARfD/ADI is exceeded (IESTI 1):**	---		**No of commodities for which ARfD/ADI is exceeded (IESTI 2):**	---		**No of commodities for which ARfD/ADI is exceeded (IESTI 1):**	---		**No of commodities for which ARfD/ADI is exceeded (IESTI 2):**	---

Conclusion: For Alpha-cypermethrin IESTI 1 and IESTI 2 were calculated for food commodities for which pTMRLs were submitted and for which consumption data are available. No exceedance of the ARfD/ADI was identified for any unprocessed commodity. For processed commodities, no exceedance of the ARfD/ADI was identified.												

Exposure calculation for metabolites

As described in detail in chapter CA 6.2 a number of alpha-cypermethrin metabolites were identified in matrices directly or indirectly related to human consumption.
To address the relevance of the alpha-cypermethrin metabolites for the human consumption, the Threshold of Toxicological Concern-Concept (TTC-Concept) was applied, which is considered by EFSA to be "the most appropriate tool for evaluating the toxicological relevance of pesticide metabolites" (Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment, EFSA Journal 2012;10(07):2799).

The following 18 compounds have to be assessed:

Metabolites
M310I001
M310I003
M310I004
M310I005
M310I006
M310I007
M310I008
M310I009
M310I010
M310I011
M310I013
M310I017
M310I018
M310I019
M310I021
M310I024
M310I025
M310I026

Exposure calculations have been performed for all metabolites mentioned above as basis for an assessment using the TTC concept.
These calculations were done using the EFSA PRIMo calculator and considering all uses to be defended in future. For each metabolite, a parent/metabolite ratio was derived from the respective metabolism studies, which was multiplied with the parent residues (STMR for the chronic risk assessment and HR for the acute risk assessment) from the supervised field trials. In the following, the calculations are summarized for the individual metabolites. The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculation are given in the supplemental information document (DocID 2014/1314800) for each metabolite.

1. M310I001

For metabolite M310I001 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.016
- ruminants muscle: 0.03
- ruminant liver: 0.78
- ruminant kidney: 4.03
- ruminant fat: 0.02
- poultry muscle: 2.63
- poultry liver: 0.01*
- eggs: 1.83

* absolute value which will not be multiplied with STMR values

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-7: Results of the chronic exposure calculations for metabolite M310I001

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (ES child)		Trigger: 0.0003 mg/kg bw/d (ES child)		Trigger: 0.0015 mg/kg bw/d (ES child)	
1st	6762	Poultry meat	56.3	Poultry meat	11.3	Poultry meat
2nd	530	Birds´ eggs	4.4	Birds´ eggs	0.9	Birds´ eggs
3rd	99.3	Swine liver	0.8	Swine liver	0.2	Swine liver
Total utilization [%]	**7835**		**65.3**		**13.1**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

2. M310I003

For metabolite M310I003 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- ruminant kidney: 1.58
- poultry liver: 0.00054*
- eggs: 0.93

* absolute value which will not be multiplied with STMR values

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-8: Results of the chronic exposure calculations for metabolite M310I003

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK infant)		Trigger: 0.0003 mg/kg bw/d (UK infant)		Trigger: 0.0015 mg/kg bw/d (UK infant)	
1st	500	Birds´ eggs	4.2	Birds´ eggs	0.8	Birds´ eggs
2nd	72.6	Bovine kidney	0.6	Bovine kidney	0.1	Bovine kidney
3rd	--	--	--	--	--	--
Total utilization [%]	**573**		**4.8**		**1.0**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

3. M310I004

For metabolite M310I004 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- ruminant liver: 0.86
- ruminant kidney: 12.95

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-9: Results of the chronic exposure calculations for metabolite M310I004

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (WHO Cluster diet B)		Trigger: 0.0003 mg/kg bw/d (WHO Cluster diet B)		Trigger: 0.0015 mg/kg bw/d (WHO Cluster diet B)	
1st	1899	Bovine kidney	15.8	Bovine kidney	3.2	Bovine kidney
2nd	126	Bovine liver	1.0	Bovine liver	0.2	Bovine liver
3rd	--	--	--	--		--
Total utilization [%]	**2025**		**16.9**		**3.4**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

4. M310I005

For metabolite M310I005 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.031

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-10: Results of the chronic exposure calculations for metabolite M310I005

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	851	sugar beet (root)	7.1	sugar beet (root)	1.4	sugar beet (root)
2nd	65.6	rice	0.5	rice	0.1	rice
3rd	48.6	wheat	0.4	wheat	0.1	wheat
Total utilization [%]	**1117**		**9.3**		**1.9**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

5. M310I006

For metabolite M310I006 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.032

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-11: Results of the chronic exposure calculations for metabolite M310I006

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	878	sugar beet (root)	7.3	sugar beet (root)	1.5	sugar beet (root)
2nd	67.8	rice	0.6	rice	0.1	rice
3rd	50.1	wheat	0.4	wheat	0.1	wheat
Total utilization [%]	**1153**		**9.6**		**1.9**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

6. M310I007

For metabolite M310I007 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.057

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-12: Results of the chronic exposure calculations for metabolite M310I007

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	1564	sugar beet (root)	13.0	sugar beet (root)	2.6	sugar beet (root)
2nd	121	rice	1.0	rice	0.2	rice
3rd	89.3	wheat	0.7	wheat	0.1	wheat
Total utilization [%]	**2053**		**17.1**		**3.4**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

7. M310I008

For metabolite M310I008 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.057

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-13: Results of the chronic exposure calculations for metabolite M310I008

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	1564	sugar beet (root)	13.0	sugar beet (root)	2.6	sugar beet (root)
2nd	121	rice	1.0	rice	0.2	rice
3rd	89.3	wheat	0.7	wheat	0.1	wheat
Total utilization [%]	**2053**		**17.1**		**3.4**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

8. M310I009

For metabolite M310I009 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.07

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-14: Results of the chronic exposure calculations for metabolite M310I009

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	1921	sugar beet (root)	16.0	sugar beet (root)	3.2	sugar beet (root)
2nd	148	rice	1.2	rice	0.2	rice
3rd	110	wheat	0.9	wheat	0.2	wheat
Total utilization [%]	**2521**		**21.0**		**4.2**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

9. M310I010

For metabolite M310I010 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.003
- ruminant liver: 0.44
- ruminant kidney: 5.06
- milk: 0.37

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-15: Results of the chronic exposure calculations for metabolite M310I010

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK infant)		Trigger: 0.0003 mg/kg bw/d (UK infant)		Trigger: 0.0015 mg/kg bw/d (UK infant)	
1st	5730	milk and cream	47.7	milk and cream	9.5	milk and cream
2nd	233	bovine kidney	1.9	bovine kidney	0.4	bovine kidney
3rd	80.9	bovine liver	0.7	bovine liver	0.1	bovine liver
Total utilization [%]	**6103**		**50.9**		**10.2**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

10. M310I011

For metabolite M310I011 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.07
- ruminant liver: 0.19
- ruminant kidney: 1.75

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-16: Results of the chronic exposure calculations for metabolite M310I011

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	1921	sugar beet (root)	16.0	sugar beet (root)	3.2	sugar beet (root)
2nd	148	rice	1.2	rice	0.2	rice
3rd	110	wheat	0.9	wheat	0.2	wheat
Total utilization [%]	**2553**		**21.3**		**4.3**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

11. M310I013

For metabolite M310I013 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.006

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-17: Results of the chronic exposure calculations for metabolite M310I013

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	165	sugar beet (root)	1.4	sugar beet (root)	0.3	sugar beet (root)
2nd	12.7	rice	0.1	rice	0.0	rice
3rd	9.4	wheat	0.1	wheat	0.0	wheat
Total utilization [%]	**216**		**1.8**		**0.4**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

12. M310I017

For metabolite M310I017 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.15

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-18: Results of the chronic exposure calculations for metabolite M310I017

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	4117	sugar beet (root)	34.3	sugar beet (root)	6.9	sugar beet (root)
2nd	318	rice	2.6	rice	0.5	rice
3rd	235	wheat	2.0	wheat	0.4	wheat
Total utilization [%]	**5402**		**45.0**		**9.0**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

13. M310I018

For metabolite M310I018 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.007

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-19: Results of the chronic exposure calculations for metabolite M310I018

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	192	sugar beet (root)	1.6	sugar beet (root)	0.3	sugar beet (root)
2nd	14.8	rice	0.1	rice	0.0	rice
3rd	11.0	wheat	0.1	wheat	0.0	wheat
Total utilization [%]	**252**		**2.1**		**0.4**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

14. M310I019

For metabolite M310I019 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- poultry liver: 2.05

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-20: Results of the chronic exposure calculations for metabolite M310I019

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (NL child)		Trigger: 0.0003 mg/kg bw/d (NL child)		Trigger: 0.0015 mg/kg bw/d (NL child)	
1st	24.0	poultry liver	0.2	poultry liver	0.0	poultry liver
2nd	--	--	--	--	--	--
3rd	--	--	--	--	--	--
Total utilization [%]	**24.0**		**0.2**		**0.0**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

15. M310I021

For metabolite M310I021 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- ruminant liver: 2.55

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-21: Results of the chronic exposure calculations for metabolite M310I021

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (IE adult)		Trigger: 0.0003 mg/kg bw/d (IE adult)		Trigger: 0.0015 mg/kg bw/d (IE adult)	
1st	1153	sheep liver	9.6	sheep liver	1.9	sheep liver
2nd	--	--	--	--	--	--
3rd	--	--	--	--	--	--
Total utilization [%]	**1153**		**9.6**		**1.9**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

16. M310I024

For metabolite M310I024 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.07

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-22: Results of the chronic exposure calculations for metabolite M310I024

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	1921	sugar beet (root)	16.0	sugar beet (root)	3.2	sugar beet (root)
2nd	148	rice	1.2	rice	0.2	rice
3rd	110	wheat	0.9	wheat	0.2	wheat
Total utilization [%]	**2521**		**21.0**		**4.2**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

17. M310I025

For metabolite M310I025 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.08

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-23: Results of the chronic exposure calculations for metabolite M310I025

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	2196	sugar beet (root)	18.3	sugar beet (root)	3.7	sugar beet (root)
2nd	169	rice	1.4	rice	0.3	rice
3rd	125	wheat	1.0	wheat	0.2	wheat
Total utilization [%]	**2881**		**24.0**		**4.8**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

18. M310I026

For metabolite M310I026 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.003

Applying the ADIs 0.0000025, 0.0003 and 0.0015 mg/kg bw/d, representing the trigger values for genotoxic potential, neurotoxic potential and Cramer class III, leads to the following results:

Table 6.9.1-24: Results of the chronic exposure calculations for metabolite M310I026

Most critical commodities	ADI utilization [%]					
	Trigger: 0.0000025 mg/kg bw/d (UK toddler)		Trigger: 0.0003 mg/kg bw/d (UK toddler)		Trigger: 0.0015 mg/kg bw/d (UK toddler)	
1st	82.3	sugar beet (root)	0.7	sugar beet (root)	0.1	sugar beet (root)
2nd	6.4	rice	0.1	rice	0.0	rice
3rd	4.7	wheat	0.0	wheat	0.0	wheat
Total utilization [%]	**108**		**0.9**		**0.2**	

The detailed input values for the chronic risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

Conclusion: Chronic risk assessments for the metabolites according to the TTC Concept

According to the TTC (Threshold of Toxicological Concern) concept for metabolites the chronic risk assessments for the 18 alpha-cypermethrin metabolites were performed.

Their potential toxicological relevance is discussed in the dossier section KCA 5.8.1. All metabolites are by weight of evidence or by direct investigation not genotoxic and not neurotoxic and thereby fall under the trigger value of Cramer Class III substances.

The calculated chronic exposure values for the compounds M310I001, M310I003, M310I004, M310I005, M310I006, M310I007, M310I008, M310I009, M310I010, M310I011, M310I013, M310I017, M310I018, M310I019, M310I021, M310I024, M310I025 and M310I026 turned out to be below 1.5 µg/kg bw/day, the trigger value of Cramer Class III substances.

Based on these data, a long-term intake of residues of these metabolites is unlikely to present a public health concern and they can be assumed to be not relevant for consumer safety.

NEDI calculations

NEDI calculations were not required as ADI utilizations for all 18 metabolites were below 100%.

Acute Reference Dose (ARfD) and Dietary Exposure Calculation

NESTI calculations

Exposure calculation for metabolites

To address the relevance of the alpha-cypermethrin metabolites for the human consumption, the Threshold of Toxicological Concern-Concept (TTC-Concept) was applied, which is considered by EFSA to be "the most appropriate tool for evaluating the toxicological relevance of pesticide metabolites" (Scientific Opinion on Evaluation of the Toxicological Relevance of Pesticide Metabolites for Dietary Risk Assessment, EFSA Journal 2012;10(07):2799).

Acute exposure was assessed for the following 18 compounds:

Metabolite
M310I001
M310I003
M310I004
M310I005
M310I006
M310I007
M310I008
M310I009
M310I010
M310I011
M310I013
M310I017
M310I018
M310I019
M310I021
M310I024
M310I025
M310I026

These calculations were done using the EFSA PRIMo calculator. For each metabolite, the parent/metabolite ratios derived from the respective metabolism studies as discussed in section 6.9.1 were used for multiplication with the parent residues (HRs) from the supervised field trials. The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculation are given in the supplemental information document (DocID 2014/1314800) for each metabolite.

1. M310I001

For metabolite M310I001 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.016
- ruminants muscle: 0.03
- ruminant liver: 0.78
- ruminant kidney: 4.03
- ruminant fat: 0.02
- poultry muscle: 2.63
- poultry liver: 0.01*
- eggs: 1.83

* absolute value which will not be multiplied with HR values

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-25: Results of the acute exposure calculations for metabolite M310I001 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	30.9	poultry meat	adults/general
2nd	29.5	poultry meat	children
3rd	20.2	scarole	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

2. M310I003

For metabolite M310I003 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- ruminant kidney: 1.58
- poultry liver: 0.00054*
- eggs: 0.93

* absolute value which will not be multiplied with HR values

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-26: Results of the acute exposure calculations for metabolite M310I003 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	5.9	bovine kidney	children
2nd	2.7	bovine kidney	adults/general
3rd	2.3	birds´ eggs swine kidney	children adults/general

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

3. M310I004

For metabolite M310I004 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- ruminant liver: 0.86
- ruminant kidney: 12.95

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-27: Results of the acute exposure calculations for metabolite M310I004 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	48.8	bovine kidney	children
2nd	22.0	bovine kidney	adults/general
3rd	18.4	swine kidney	adults/general

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

4. M310I005

For metabolite M310I005 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.031

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-28: Results of the acute exposure calculations for metabolite M310I005 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	39.1	scarole	children
2nd	24.7	kale	children
3rd	15.6	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

5. M310I006

For metabolite M310I006 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.032

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-29: Results of the acute exposure calculations for metabolite M310I006 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	40.4	scarole	children
2nd	25.5	kale	children
3rd	16.1	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

6. M310I007

For metabolite M310I007 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.057

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-30: Results of the acute exposure calculations for metabolite M310I007 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	72.0	scarole	children
2nd	45.5	kale	children
3rd	28.6	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

7. M310I008

For metabolite M310I008 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.057

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-31: Results of the acute exposure calculations for metabolite M310I008 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d

2nd	45.5	kale	children
3rd	28.6	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

8. M310I009

For metabolite M310I009 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.07

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-32: Results of the acute exposure calculations for metabolite M310I009 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	88.4	scarole	children
2nd	55.8	kale	children
3rd	35.1	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

9. M310I010

For metabolite M310I010 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.003
- ruminant liver: 0.44
- ruminant kidney: 5.06
- milk: 0.37

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-33: Results of the acute exposure calculations for metabolite M310I010 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	19.1	bovine kidney	children
2nd	9.2	milk and milk products	children
3rd	8.6	bovine kidney	adults/general

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

10. M310I011

For metabolite M310I011 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.07
- ruminant liver: 0.19
- ruminant kidney: 1.75

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-34: Results of the acute exposure calculations for metabolite M310I011 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	88.4	scarole	children
2nd	55.8	kale	children
3rd	35.1	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

11. M310I013

For metabolite M310I013 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.006

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-35: Results of the acute exposure calculations for metabolite M310I013 using default variability factors (IESTI 1)

1st	101	scarole	children
2nd	63.8	kale	children
3rd	40.1	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

18. M310I026

For metabolite M310I026 the parent/metabolite ratios were as follows (for details see chapter 3.2 of the supplemental information document (DocID 2014/1314800)):

- all plants: 0.003

Applying the ARfD of 0.005 mg/kg bw/d, representing the trigger value for Cramer class III, leads to the following results:

Table 6.9.1-42: Results of the acute exposure calculations for metabolite M310I026 using default variability factors (IESTI 1)

Most critical commodities	Trigger: 0.005 mg/kg bw/d		
	ARfD utilization [%]	Commodity	Population
1st	3.8	scarole	children
2nd	2.4	kale	children
3rd	1.5	spinach	children

The detailed input values for the acute risk assessment and the results of the EFSA PRIMo calculations are given in in the supplemental information document (DocID 2014/1314800).

Conclusion: Acute risk assessments for the metabolites according to the TTC Concept

According to the TTC (Threshold of Toxicological Concern) concept for metabolites the acute risk assessments for the 18 alpha-cypermethrin metabolites were performed.

Their potential toxicological relevance is discussed in the dossier section KCA 5.8.1. All metabolites are by weight of evidence or by direct investigation not genotoxic and not neurotoxic and thereby fall under the trigger value of Cramer Class III substances.
The calculated maximum acute exposure values for the compounds M310I001, M310I003, M310I004, M310I005, M310I006, M310I007, M310I008, M310I009, M310I010, M310I011, M310I013, M310I018, M310I019, M310I021, M310I024 and M310I026 turned out to be below 5 µg/kg bw/day.

For metabolites M310I017 and M310I025 ARfD utilizations slightly above the trigger value were observed but by weight of evidence the toxicity data (see KCA 5.8.1) do not indicate a relevant concern for acute toxicity at the respective exposure level.
Based on these data, a short-term acute intake of residues of these metabolites is unlikely to present a public health concern and they can be assumed to be not relevant for consumer safety.

CA 6.10 Other studies

No other/special studies are deemed necessary. The studies and information provided in the previous sections are considered adequate and sufficient.

CA 6.10.1 Effect on the residue level in pollen and bee products

The objective of these studies shall be to determine the residue in pollen and bee products for human consumption resulting from residues taken up by honeybees from crops at blossom.

The representative uses of this dossier are cereals, oil seed rape, leafy brassica, lettuce and cucumber. Cereals are generally considered to be of low attractiveness to honey bees for pollen collection (although not fully excluded) and collection of nectar is not relevant (EFSA, 2013). Moreover, cereals are considered to have no melliferous capacity. Lettuce and leafy brassica vegetables are harvested before flowering, hence these crops are not relevant regarding potential exposure of bees to residues. The pollen/nectar from cucumber and courgette cultivated in greenhouses is assumed to have a negligible contribution to the total pollen/nectar foraged by honeybees for several reasons: Greenhouses represent an enclosed in-door system, often with limited direct access for honey bees and other pollinators. For that reason, often commercially bread bumble bees are specifically introduced into greenhouses to perform the pollination activity on crops such as cucurbits, tomatoes, peppers, etc., grown in greenhouses. Furthermore, when considering that the representative use on oilseed rape - which is cultivated over a much larger field area (the EU cucumber production area (greenhouse plus field) represents only 2% of the EU oil seed rape production area) - and which is treated during flowering – the oil seed rape use represents the realistic worst-case scenario with regard to the foraging by bees in view of honey production.
Due to the lack of an appropriate guidance document, but driven by the fact that oil seed rape is a fodder crop for honey bees the residue in pollen and derived bee products was evaluated. Studies were conducted to determine the effects of BAS 310 I on bees and to derive ecotoxicological endpoints. In these studies, residues of alpha-cypermethrin were determined in pollen and nectare and in honey. These studies are summarized in Document M-CP, Section 10 chapter CP 10.3.1 of this dossier. As expected from the low water solubility and the non-systemicity of alpha-cypermethrin these studies demonstrate that a transfer of residue from flowers into honey is insignificant. The consumer risk in honey consumption resulting from the uses of alpha-cypermethrin is therefore considered as negligible.

In the application, the study with the title “Determination of residues of BAS 310 55 I in nectar, pollen and flowers of winter oil seed rape after one application in Germany 2013”, Mack P., 2014, BASF DocID 2014/1000203, is listed as reference no. KCA 6.10.1/1. In deviation from this order, this study is not summarized in this section (CA 6.10.1), but in CP 10.3.1 (report CP 10.3.1.6/7).

Tier 1 Summaries of the Supervised Field Residue Trials for the Representative Crops

- **Cucumber**

Northern Europe

RESIDUE DATA SUMMARY FROM SUPERVISED TRIALS (SUMMARY)

Active substance (common name)	Alpha-cypermethrin	**Commercial Product (name)**	-
Crop/crop group:	Cucumber (fruiting vegetables, cucurbits edible peel)	**Producer of commercial product**	BASF SE
Responsible body for reporting (name, address)	BASF AG, 67056 Ludwigshafen	**Indoor/Glasshouse/Outdoor**	Glasshouse
Country	Denmark, France, Germany, The Netherlands	**Other active substance in the formulation**	None
Content of active substance (g/kg or g/L)	100 g/L	**(common name and content)**	
Formulation (e.g. WP)	SC (BAS 310 41 I)	**Residues calculated as:**	Alpha-cypermethrin

RESIDUE DATA SUMMARY FROM SUPERVISED TRIALS (SUMMARY)

Active substance (common name)	Alpha-cypermethrin	**Commercial Product (name)**	-
Crop/crop group:	Grapes/Berries and small fruits	**Producer of commercial product**	67056 Ludwigshafen, Germany
Responsible body for reporting (name, address)	BASF SE, 67056 Ludwigshafen	**Indoor/Glasshouse/Outdoor**	Outdoor
Country	France, Germany	**Other active substance in the formulation**	none
Content of active substance (g/kg or g/L)	100 g/L	**(common name and content)**	
Formulation (e.g. WP)	BAS 310 40 I (EC)	**Residues calculated as:**	Alpha-Cypermethrin (BAS 310 I)

CA 7 FATE AND BEHAVIOUR IN THE ENVIRONMENT

A concordance list of structures and designations of reference compounds used during environmental fate studies is given below. During the registration history of alpha-cypermethrin several different code systems were used for the designation of cypermethrin isomers and metabolites. Some of the structures and codes in Table 7-1 were only used in studies that are no longer considered valid for the evaluation of alpha-cypermethrin.
The already peer-reviewed studies as well as the new studies were performed using cyclopropyl-ring and benzyl-ring ^{14}C-labelled alpha-cypermethrin.

"RP xxxxx" or or "RPxxxxx" or "RP0xxxxx"
Independent from these format differences, the last 5 digit "xxxxx" are unique for every compound

CA 7.1 Fate and behaviour in soil

Alpha-cypermethrin is the cis-2 isomer of cypermethrin. In the past many studies performed with cypermethrin were submitted to support the registration of alpha-cypermethrin. In the current approach it was tried to rely on studies performed with alpha-cypermethrin wherever possible.

CA 7.1.1 Route of degradation in soil

Many studies were performed with cypermethrin or alpha-cypermethrin during its registration history. An overview is given in Table 7-1. Most of them were no longer considered as relevant, due to high overdosing, insufficient duration or no longer state of the art identification techniques.

The degradation of alpha-cypermethrin was addressed by the following studies, which were no longer considered valid:

1. The degradation of the insecticide WL 43467 in soil under laboratory conditions (Standen 1976, AL-620-008, published by Roberts 1977, AL-905-062)
In this study, the degradation of cypermethrin and its isomers WL 43481 (both cis isomers) and WL 42641 (both trans isomers) were studied in three soils, two from Spain and one UK soil. The study was conducted with both labels and under aerobic and anaerobic conditions. The main route of degradation was the cleavage of the ester linkage forming DCVA (SD 44776) and 3-PBA (36750) as major metabolites. In one soil the degradation was very slow, because soil moisture was too low. A separate balance study was conducted for 182 days.
2. Further studies on the degradation of the insecticide WL 43467 (cypermethrin) in soil under laboratory conditions (Standen 1978, CY-620-003).
The same soils were used as in Standen (1976) but the study was prolonged to 1 year. No intermediate samples were taken. In a second experiment an additional UK soil was used to investigate the degradation of cis-DCVA (WL 43480) and trans-DCVA (WL 42640). It was incubated for 56 days and a dicarboxylic acid was identified as degradation product.

The studies of Standen (1976) and Standen (1978) were also submitted in the application for zeta-cypermethrin. These were evaluated by EFSA (EFSA Scientific Report (2008) 196, 1-119) and it was concluded that these studies should not be relied on for regulation. In the study no material balance is available, as no volatiles were trapped and samples were only taken at 4 intervals.

3. Degradation and leaching behaviour of the pyrethroid insecticide cypermethrin in soil (Sakata et al. 1986, published literature, CY-620-012)
The study was conducted with benzyl- or cyclopropyl- ^{14}C labelled cis and trans isomers of cypermethrin. Two experiments were described; a degradation in two acidic Japanese soils and a column leaching experiment in four Japanese soils. The comparison of cis and trans isomers shows that trans isomers degrade faster that cis isomers.
The study of Sakata (1985) was considered as supportive information. No information on the history of the soils was given. As the study was not conducted under GLP, no raw data are available and not all results were included in the publication.

The following studies were already not regarded in the existing Annex 1 listing due to their poor quality or because they did not follow current guidelines (Alpha-cypermethrin - Annex B - pages 387-389):

4. Degradation of pyrethroid optical isomers in soils (Sakata et al., 1992, published literature, AL-905-078)
5. The metabolism of WL 43467 (Cypermethrin) in lettuce and soil under outdoor conditions (Wright, 1977; AL-790-002)

6. The degradation of the pyrethroid insecticides WL 85871 (FASTAC) and WL 43481 in soil (McMinn, 1983; AL-620-005)

7. The bioavailability and further degradation of bound residues arising from WL 43867 (Standen 1978,)

8. Soil percolation studies with WL 43467 (Noble, 1976; AL-620-009)

9. Persistence of five pyrethroid insecticides in sterile and natural mineral and organic soil (Chapman et al. 1981, published literature)

10. Metabolism of alphamethrin (Alphaguard 25% EC M/M) in soil (Raghunahan, 1989, Gharda)

11. Studies on the persistence of alphamethrin (Alphaguard 10% EC M/M) in water (Raghunahan, 1991, Gharda)

CA 7.1.1.1 Aerobic degradation

Report:	CA 7.1.1.1/1 Michel, A., Hassink, J., 2014 a Metabolism of BAS 310 I in Soil under Aerobic Conditions 2014/1000641
Guidelines:	OECD 307, EPA 835.4100, SETAC Procedures for assessing the environmental fate and ecotoxicity for pesticides (March 1995)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Report:	CA 7.1.1.1/2 Hassink J., 2015 a Report amendment no. 1 to final report: Metabolism of BAS 310 I in soil under aerobic conditions 2015/1107644
Guidelines:	EPA 835.4100, OECD 307, BBA IV 4-1, SETAC Procedures for assessing the environmental fate and ecotoxicity for pesticides (March 1995)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

The amendment to the report contains KinGUI graphs of the parameter estimation section that were missing in the final report.

Executive Summary

The objective of this study was to investigate the rate of degradation of cyclopropane-1-^{14}C-labeled-alpha-cypermethrin (cyclopropane label) and benzyl-^{14}C-labeled-alpha-cypermethrin (benzyl label) in soil, to propose a degradation pathway under aerobic conditions and to define potentially occurring metabolites.

Each test item was incubated aerobically in a loamy sand (sandy loam, according to USDA) soil at 20ºC and 50% maximum water holding capacity (pF 2.5) in the dark for 120 days. The nominal application rate was 0.3 mg kg^{-1} dry soil. Soil aliquots were weighed into test vessels and placed into an incubation cabinet. A closed incubation system with continuous aeration was used with an attached trapping system for the determination of volatile compounds. Absorption solutions were removed at each sampling event.

At about 60 DAT and at the end of the incubation period after 120 days the microbial biomass was determined by the substrate induced respiration method.

Soil samples were taken at 0, 1, 3, 7, 10, 14, 31, 59, 92 and 120 days after treatment (DAT) for the benzyl label and at 0, 1, 3, 7, 10, 14, 31, 63, 91 and 122 DAT for cyclopropane label. At sampling times 0 and 60 DAT, soil samples were worked up in duplicate. The soil samples were extracted four times with acetonitrile/water (7/3, v/v). The extracts were analyzed by LSC and HPLC. The remaining soil after extraction was combusted, in order to determine the amount of non-extractable soil bound residues. A full material balance was provided for each sampling interval.

The amount of extractable radioactivity continuously decreased from 97.8% TAR at day 0 to 9.7% TAR after 122 days of incubation for the cyclopropane label and from 98.1% TAR at day 0 to 9.1% TAR after 120 days of incubation for the benzyl-^{14}C-label. The non-extractable radioactive residues (NER) increased from 2.2% TAR on day 0 to a maximum of 48.7% TAR after 122 days of incubation for the cyclopropane label and from 1.9% TAR on day 0 to a maximum of 47.4% TAR after 120 days of incubation for the benzyl-^{14}C-label. Mineralization to $^{14}CO_2$ reached a total of 33.9% TAR after 122 days of incubation for the cyclopropane label and 34.0% TAR for the benzyl-^{14}C-label. Other volatile compounds could not be detected in significant amounts at any time. The material balance ranged from 78.9 to 100.0% TAR for the cyclopropane label and from 88.2 to 103.3% TAR for the benzyl-^{14}C-label.

The NER fraction was further characterized for one replicate from each sampling. Upon extraction with NaOH and water, about 8.6% TAR of the NER remained unextractable from the soil treated with the cyclopropane label and 13.4% TAR remained unextractable from the soil treated with the benzyl-^{14}C-label. This portion of unextractable radioactivity was assigned to the humin fraction. The alkali-soluble radioactivity was further fractionated by precipitation with concentrated HCl to distinguish between acid-insoluble humic acids and acid-soluble fulvic acids. For the cyclopropane label, 19.9% of TAR could be assigned to the fulvic acid fraction at the end of the incubation. For the benzyl-^{14}C-label, a maximum of 18.2% of TAR could be assigned to the fulvic acid fraction after 60 days. At 90 DAT, 7.0% TAR and 9.4% TAR were assigned to the humic acids fraction for the cyclopropane label and the benzyl label, respectively. The fulvic acid fraction was partitioned with ethyl acetate for three exemplary samples (10, 63 and 122 DAT (cyclopropane label), 10, 59 and 120 DAT (benzyl label)). A maximum of about 9.0% and 5.6% of the fulvic acid fraction were soluble in the ethyl acetate phase at 60 DAT for the cyclopropane label and the benzyl label, respectively.

Besides the parent compound, two metabolites DCVA (3-(2,2-dichlorovinyl)-2,2-dimethyl cyclopropanecarboxylic acid) and M310I017 were observed. Parent compound and the metabolites were positively identified by time-of-flight mass spectrometry with electrospray ionization (ESI-Q-TOF). For the metabolite DCVA, the identification was confirmed by comparison of retention times with reference compounds.

The parent compound decreased continuously from 96.7% TAR at 0 DAT to 4.2% TAR after 122 days of incubation (for the cyclopropane label) and from 96.2% TAR at 0 DAT to 2.7% TAR after 120 days of incubation (for the benzyl label).

The metabolite DCVA was only observed in the extracts of the soil spiked with the cyclopropane label. It was first observed on day 3 after application, increased to about 13.6% TAR at 7 DAT and decreased to 4.9% TAR at 14 DAT. The metabolite M310I017 was observed with both labels. For the soil spiked with cyclopropane label, it was first detected at day 1 after application, increased to max. 8.4% TAR at 7 DAT and declined to 0.3% TAR at the end of the study. For the soil spiked with benzyl label, it was first detected at day 3 after application, increased to max. 7.5 % TAR at 7 DAT and declined to 2.0% TAR at the end of the study.

Kinetic evaluation was performed following the recommendations of the FOCUS Kinetics workgroup in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. The $DegT_{50}$/$DegT_{90}$ values for alpha-cypermethrin and its metabolites, DCVA, and M310I017 were determined as summarized in the table below (Table 7.1.1.1-1).

Table 7.1.1.1-1: Trigger and Modeling Endpoints for alpha-cypermethrin, DCVA, and M310I017 (non-GLP)

Compound	Label	Trigger endpoints			Modeling endpoints	
		Best-fit model	$DegT_{50}$ [d]	$DegT_{90}$ [d]	Best-fit model	$DegT_{50}$ [d]
alpha-cypermethrin	Cyclopropane-^{14}C	DFOP	3.1	42.2	FOMC	14.5[a]
	Benzyl-^{14}C	FOMC	3.9	43.5	FOMC	13.1[a]

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS-Code: BAS 310 I (alpha-cypermethrin)
Chemical name: Racemate of (S)-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Molecular formula: $C_{22}H_{19}Cl_2NO_3$
Molar mass: 416.3 g mol^{-1} (unlabeled)

Label 1 (cyclopropane label)
Label: cyclopropane-1-^{14}C
Batch No.: 986-1046
Specific radioactivity of a.s.: 4.9 MBq mg^{-1}
Radiochemical purity: 98.2%
Chemical purity: 93.6%

Label 2 (benzyl label)

Label:	benzyl-^{14}C
Batch No.:	775-0401
Specific radioactivity of a.s.:	4.94 MBq mg^{-1}
Radiochemical purity:	96.1%
Chemical purity:	93.7%

2. Soil

The German soil LUFA 5M from LUFA (Landwirtschaftliche Untersuchungs- und Forschungsanstalt, Speyer, Germany) was used in this study. It was sampled from 0-20 cm depth. The soil was passed through a 2 mm sieve and stored for no longer than three months at 4°C before use. The soil characteristics are summarized in Table 7.1.1.1-2.

Table 7.1.1.1-2: Characteristics of soil LUFA 5M

Soil designation	**LUFA 5 M** **12/1651/03** (Germany, Origin: LUFA Speyer)
DIN Particle size distribution [%]	
Sand 0.063 – 2 mm	54.9
Silt 0.002 – 0.063 mm	32.9
Clay < 0.002 mm	12.2

B. STUDY DESIGN

1. Experimental conditions

The test substance was applied at a nominal concentration of 0.08 mg alpha-cypermethrin per kg dry soil which corresponds to a field application rate of 30 g a.s. ha^{-1} (calculated on the basis of an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g cm^{-3}). Because of the low specific radioactivity of the test items and to ensure a better detection of possible degradation products, the amount of test item applied was increased to 0.3 mg test item kg^{-1} dry soil.

Before application the soil was readjusted to 50% of the respective maximum water holding capacity (MWHC). After application to bulk soil, portions of 100 g soil (dry weight basis) were filled into test vessels. The actual application rate was 0.31 mg kg^{-1} for the cyclopropane-1-^{14}C-labeled alpha-cypermethrin (cyclopropane label) and 0.29 mg kg^{-1} for the benzyl-^{14}C-labeled alpha-cypermethrin (benzyl label). The mean value of the sum of extractable (ERR) and non-extractable radioactive residues (NER) at day 0 in 100 g dry soil was set to 100% TAR (total applied radioactivity).

For incubation, all test vessels were connected in line with aeration tubes in the soil metabolism apparatus. During the study, samples were continuously aerated with a slight stream of moistened synthetic air. For removing carbon dioxide, the air was passed through a bottle with NaOH before passing the test vessels. For trapping of volatiles possibly evolving from soil during the incubation, test vessels were connected to three gas washing flasks containing 50 mL ethylene glycol, 50 mL 0.5 M H_2SO_4, and 50 mL 0.5 M NaOH. The treated soils were incubated at 20 ± 2°C in the dark.

To determine the microbial biomass at 0, 60 and 120 days after treatment, three additional soil portions (1 kg dry soil equivalents, 50% MWHC) were incubated under the same conditions as the ^{14}C-treated samples. The first series was incubated without additional treatment. A second series was treated with 300 µL acetonitrile (ACN; without test item). A third series was treated with 280 µL of the specific application solution containing the unlabeled test item.

2. Sampling

Sampling dates were 0, 1, 3, 7, 10, 14, 31, 63, 91 and 122 days after treatment (DAT) for the cyclopropane labeled test item and 0, 1, 3, 7, 10, 14, 31, 59, 92 and 120 DAT for the benzyl labeled test item. At each sampling date two replicate samples were collected. One soil sample was completely worked up, the second replicate was stored in a freezer. On day 0 and day 60 two soil samples were worked up and two were stored.

Besides day 0, the volatile trapping solutions were sampled and replaced by new flasks with fresh solutions. The sampled trapping solutions were measured for radioactivity by LSC.

3. Description of analytical procedures

For the determination of ERR, the 100 g (dry weight basis) soil samples were consecutively extracted four times with 120 mL acetonitrile (ACN)/water (7/3, v/v) by mechanical shaking for 1 h. After centrifugation, the four ACN/water-extracts were pooled and analyzed by liquid scintillation counting (LSC).

Radio-HPLC was used to show the purity of the test items and to investigate the metabolism of the cyclopropane- and the benzyl-labeled test item. HPLC system 1 was used to quantify the test item and the metabolites, HPLC system 3 was applied for the separation of cis and trans isomers, and HPLC system 5 was used for the separation of enantiomers. The HPLC system 4 was used for the analysis of the water phase separated from the ethyl acetate for the characterization of the fulvic acids fraction.

Depending on the subsequent used HPLC-method, different sample workups were performed.

To determine the metabolite pattern, aliquots of the soil extracts were concentrated (rotary evaporator T ≈ 35°C). Afterwards, the residues were diluted with ACN and analyzed by radio-HPLC (HPLC system 1). Separation of cis and trans isomers, as well as enantiomers of alpha-cypermethrin was performed on HPLC system 3 and 5, respectively. For this, aliquots of the soil extracts were evaporated to dryness (rotary evaporator T ≈ 35°C), redissolved in ACN/water (7/3, v/v) and analyzed by LSC and radio-HPLC.

The soil residues remaining after extraction were air-dried, homogenized by means of a small mill, and three aliquots were combusted in an oxidizer. The evolved $^{14}CO_2$ from each combusted aliquot was trapped in Oxysolve C-400 scintillator and measured by LSC to determine the amount of the non-extractable residues (NER).

The fraction of NER was further characterized by NaOH extractions (0.5 M NaOH, three times). NaOH extracts were processed to determine the distribution of radioactivity to the humin, humic, and fulvic acid fractions. The humic acid fraction and the fulvic acid fraction were analyzed by LSC. The fulvic acid fraction was further partitioned with ethyl acetate. Concentrated ethyl acetate phases were analyzed by HPLC. The remaining radioactivity in the soil residues was determined by combustion analyses (humin fraction). Further details are given in the report.

The fulvic acid fraction was partitioned three times with ethyl acetate. After pooling, the ethyl acetate phase was analyzed by LSC.

The microbial biomass in the soil samples treated with and without solvent was determined at 0, 60 and 120 DAT. The method was based on the determination of oxygen consumption upon addition of glucose. The microbial biomass declined over the incubation phase. However, the results demonstrate that the soil was still viable and microbially active at days 60 and 120 (end) of the study.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values was performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006) "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 2.0, 434 pp.*].

The software package KinGUII (version 2.2014.224.1704) was used for parameter fitting [*SCHÄFER, D., MIKOLASCH, M., RAINBIRD, P., HARVEY, B. (2007) KinGUI: A new kinetic software tool for evaluations according to FOCUS Degradation Kinetics. In: Del Re, A.A.M. et al. (Eds.): Proceedings of the XIII Symposium on Pesticide Chemistry, Piacenza, 2007, p. 916-923*., *WITT, J., GAO, Z., MEYER, H. (2014) KinGUII, Version 2.2014.224.1704 Bayer CropScience AG*]. The error tolerance and the number of iterations of the optimization tool were set to 0.00001 and 100, respectively.

For each data set, the kinetic models proposed by the FOCUS Kinetics guidance document were tested in order to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO), the Gustafson-Holden model (FOMC), and bi-exponential (DFOP) kinetics are already implemented in KinGUI. The Goodness-of-fit was evaluated by visual assessment, χ^2 minimum error, and type-I-error rate (t-test) [for details see Chapter 6.3 in FOCUS (2006)].

Where available, replicate measurements were considered for the parameter estimation. The initial concentration of the applied test item was set to the material balance recovered at day 0. The χ^2 value for the kinetic model was calculated as recommended by FOCUS, considering the average of replicate measurements. For the individual parameters, the t-test statistics were based on number of individual measurements.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues and the overall mass balances are presented in Table 7.1.1.1-3. The mass balance ranged from 78.9% TAR to 100.0% TAR and from 88.2% TAR to 103.3% TAR for the cyclopropane label and the benzyl label, respectively.

B. EXTRACTABLE AND BOUND RESIDUES

The amount of extractable radioactive residues continuously decreased from 97.8% TAR at 0 DAT to 9.7% TAR at 122 DAT for the cyclopropane label and from 98.1% TAR at 0 DAT to 9.1% TAR at 120 DAT for the benzyl label.

The amount of non-extractable residues increased from 2.2% TAR immediately after treatment to 48.7% TAR after 122 days of incubation for the cyclopropane label and from 1.9% TAR immediately after treatment to 47.4% TAR after 120 days of incubation for the benzyl label. The NER fraction was further characterized by fractionation into humins, humic and fulvic acids.

Table 7.1.1.1-3: Mass balance and distribution of radioactivity after application of ^{14}C-labeled-alpha-cypermethrin to soil [% TAR]

n.a. = Not analyzed
* No other volatiles than CO_2 were found

C. VOLATILIZATION

Carbon dioxide was the only trapped volatile degradation product found in the sodium hydroxide traps reaching 33.9% TAR and 34.0% TAR after 122 days of incubation for the cyclopropane label and the benzyl label, respectively. In sulfuric acid and ethylene glycol no significant radioactivity could be measured at any time.

D. TRANSFORMATION OF PARENT COMPOUND

Aliquots of all sample extracts were analyzed by radio-HPLC (see Table 7.1.1.1-4).

Peak assignment of alpha-cypermethrin was performed by comparison to the retention time of the application solution and by mass spectrometry (10 DAT sample). One metabolite (DCVA) was identified by mass spectrometry (10 DAT sample) and comparison of retention times to a reference item. The identification of the metabolite M310I017 was achieved by mass spectrometry. The identity of M310I017 was additionally confirmed by chromatographic comparison to a reference sample from the aerobic soil degradation study [*CA 7.1.2.1.1/4, BASF DocID 2014/1159491*].

The amount of alpha-cypermethrin decreased throughout the incubation from 96.7 % TAR at 0 DAT to 4.2% TAR at the end of the study for the cyclopropane label. For the soils spiked with benzyl label, the amount of alpha-cypermethrin decreased from 96.2% TAR at 0 DAT to 2.7% TAR at the end of the study.

The metabolite DCVA was only observed in the extracts of the soil treated with the cyclopropane label. It was detected with max. 13.6% TAR at 7 DAT and decreased to 4.9% TAR at 14 DAT.

The metabolite M310I017 was observed with both labels. For the soil samples spiked with the cyclopropane label, the amount of metabolite M310I017 increased to max. 8.4% TAR at 7 DAT and decreased to 0.3% TAR at the end of the study. For the soil samples spiked with the benzyl label, the amount of metabolite M310I017 increased to max. 7.5% TAR at 7 DAT and decreased to 2.0% TAR at 59 DAT.

DAT = Days after treatment
n.d. = Not detected
* Individual peaks < 5.0% TAR

Further HPLC analysis revealed that only the cis isomer of alpha-cypermethrin was present in the sample extracts throughout the study and that no trans isomer was formed.

No change of the enantiomeric ratio could be observed during the study irrespective of the radiolabel.

E. CHARACTERIZATION OF NON-EXTRACTABLE RESIDUES (NER)

Results of the non-extractable residues characterization performed by humic substance fractionation are given in Table 7.1.1.1-5 to Table 7.1.1.1-7.

Upon extraction with NaOH and water, about 8.6% and 13.4% of the NER remained unextractable for the cyclopropane label and the benzyl label, respectively. This portion was assigned to the humin fraction. The alkali-soluble radioactivity was further fractionated. For the cyclopropane label, 19.9% TAR could be assigned to the fulvic acids fraction (after 122 days) and maximum 7.0% TAR to the humic acids fraction at 91 DAT. For the benzyl label, 18.2% TAR could be assigned to the fulvic acids fraction (at 59 DAT) and maximum 9.4% TAR to the humic acids fraction at 92 DAT. The humic acid fraction was not further analyzed.

The fulvic acid fraction was partitioned with ethyl acetate for three exemplary samples (10, 59/63 and 120/122 days). About 9.0% and 5.6% of the fulvic acid fraction were soluble in the ethyl acetate phase at 63/59 DAT for the cyclopropane label and the benzyl label, respectively. HPLC analyses of the water phase of the fulvic acid fraction revealed the presence of one main peak and two small peaks. The main peak was found to occur with a maximum of 5.3 % TAR at 63 DAT for the cyclopropane label and 6.3% TAR at 120 DAT for the benzyl label. No further attempts were made to identify the compounds observed in the water phase of the fulvic acid.

During the extraction of NERs by NaOH, strong alkaline conditions were reached. Alpha-cypermethrin is known to be quickly hydrolyzed in alkaline conditions [*CA 7.2.1.1/1, BASF DocID 2005/1016375*]. It is therefore likely that the compounds observed by HPLC in the water phase of the fulvic acid fraction were created during the extraction by NaOH, i.e. alkaline hydrolysis.

F. KINETIC MODELING RESULTS

The degradation of alpha-cypermethrin could be best described by bi-phasic kinetic fit (FOMC or DFOP). For the metabolites DCVA and M310I017 the first-order kinetic model was selected. A summary of the $DegT_{50}$ and $DegT_{90}$ values of alpha-cypermethrin and its metabolites DCVA and M310I017 derived as trigger and modeling endpoints are given in Table 7.1.1.1-8 and Table 7.1.1.1-9. The kinetic evaluation for the metabolite was conducted by fitting the decline curve of the metabolite starting from the peak (maximum measured amount) as proposed by FOCUS. Therefore, no formation fraction could be delineated.

Table 7.1.1.1-8: Trigger endpoints for alpha-cypermethrin, DCVA, and M310I017 (non-GLP)

Compound	Label	Best-fit model	χ^2 error	type I error rate (Prob. > t)	Visual fit	$DegT_{50}$ [d]	$DegT_{90}$ [d]

III. CONCLUSION

Alpha-cypermethrin was rapidly degraded in a loamy sand soil. The fraction of non-extractable residues increased to about 48% TAR at the end of the study after 120 days. $^{14}CO_2$ was formed in amounts up to 33.9 - 34.0% TAR. No other volatile compounds were detected in significant amounts.

Two metabolites DCVA and M310I017 were confirmed with maximum concentrations of 13.6% TAR and 8.4 - 7.5% TAR, respectively. The metabolite DCVA was only observed in the extracts of soil spiked with the cyclopropane-^{14}C-label. No benzyl-specific metabolites could be identified.

According to the best fit kinetics, $DegT_{50}$ values of 3.1 days and 3.9 days were calculated as trigger endpoints for cyclopropane-1-^{14}C-labeled-alpha-cypermethrin and benzyl-^{14}C-labeled-alpha-cypermethrin, respectively. The corresponding calculated modeling endpoints were 14.5 and 13.1 days for the cyclopropane-labeled and the benzyl labeled test item, respectively.

For DCVA, a $DegT_{50}$ value of 5.2 days was calculated as trigger and modeling endpoint, according to the best fit kinetics.

For M310I017, $DegT_{50}$ values of 8.5 and 19.9 days were calculated as trigger and modeling endpoints for the experiment using the cyclopropane-labeled and benzyl-labeled test item, respectively.

The RMS BE has asked for additional kinetic evaluations on 27. Oct. 2016. The results are presented and discussed below.

Report:	CA 7.1.1.1/3 Anonymous, 2016 a Response to RMS BE - Request concerning kinetic re-evaluations – Alpha-cypermethrin 2016/1324158
Guidelines:	none
GLP:	no

RMS: RMS notes that the Notifier performed a separate kinetic assessment for each label. In peer review, it is common practice to handle residuals from the same soil with different radiolabelled positions as replicate values. Please Notifier consider that residue data from two tested labels from the same soil have to be processed as replicates, for the determination of the kinetic parameters of alpha-cypermethrin and its metabolites.

BASF response: A kinetic evaluation was performed by processing the residue data of the two tested labels as replicates. The results are summarized in Table 7.1.1.1-10 and the corresponding Kingui fits are presented in Appendix 1. in the original response document. The trigger and modeling endpoints (DT_{50} = 3.8 d, DT_{90} = 45.7 d, modeling DT_{50} = 13.8 d, FOMC model) are comparable with those derived by performing a separate kinetic assessment for each label (geomean DT_{50} = 3.5 d, geomean DT_{90} = 42.8 d, geomean modeling DT_{50} = 13.8 d). Therefore, the endpoints presented in the dossier under CA 7.1.1.1/1 are considered adequate.

CA 7.1.1.2 Anaerobic degradation

Report:	CA 7.1.1.2/1 Staudenmaier H., Kuhnke G., 2014 a Anaerobic soil metabolism of alpha-cypermethrin (BAS 310 I) 2013/1386602
Guidelines:	OECD 307 (2002), EPA OPPTS 835.4200
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The anaerobic soil metabolism of alpha-cypermethrin (BAS 310 I) was investigated in a German loamy sand soil (according to the German soil classification scheme DIN) in the laboratory. The nominal application rate was 0.3 mg ^{14}C-labeled alpha-cypermethrin per kg dry soil. Two different labeling positions, benzyl-U-^{14}C and cyclopropane-1-^{14}C, were tested in separate experiments. A mixture of ^{14}C- and ^{13}C-labeled test items (1/1) was applied at an exaggerated rate to obtain samples allowing for the identification of unknown metabolites. After application, the treated soil was incubated in the dark under aerobic conditions at 20°C at a moisture content close to pF 2.5. A closed incubation system with continuous aeration was used.

After 9 days (approximately one half-life of the test item) the soil was covered by a water layer of about 1-2 cm depth and the incubation system was flushed with nitrogen in order to establish anaerobic conditions. The establishment of anaerobic conditions was monitored by measuring the oxygen content, the redox potential, and the pH of the test system at each sampling time from 9 days after treatment (DAT) onwards. The degradation of the test item was followed until 120 DAT. Samples were taken at 0, 1, 3, 6, 8, 10, 14, 27, 45, 62, 90 and 120 DAT. Volatiles were collected in traps attached to the incubation system.

The soil samples were extracted four times with acetonitrile/water and twice with acetonitrile. During the anaerobic phase for the first extraction, acetonitrile was added to the soil-water-slurry to obtain an acetonitrile/water ratio of 1/1 (v/v). This extraction was followed by three extractions with acetonitrile/water (7/3, v/v) and two extractions with acetonitrile. The individual extracts were analyzed by means of liquid scintillation counting (LSC) and the combined extracts by means of High Performance Liquid Chromatography (HPLC). The remaining soil after extraction was combusted in order to determine the amount of non-extractable residues. The latter were further characterized by subsequent NaOH treatment of samples from 3 DAT onwards.

The amount of parent compound decreased continuously from 95.1% of the total applied radioactivity (TAR) and 99.5% TAR at the beginning to 13.0% TAR and 11.1% TAR at 120 DAT with the benzyl and cyclopropane label, respectively. With each label, one prominent label specific metabolite was detected: M310I011 (3-PBA) with the benzyl label and M310I001 (DCVA) with the cyclopropane label. M310I011 increased from 1.5% TAR at day 0 to 30.0% TAR at 120 DAT (end of incubation). M310I001 increased from 0.9% TAR at day 0 to 55.6% TAR at 120 DAT. The label specific metabolite M310I013 was detected with the benzyl label up to 2.2% TAR. Two further metabolites were detected with both labels: M310I022 and M310I017. M310I022 was found from 62 DAT onwards with maximal amounts of 2.9% TAR for the benzyl label and 4.3% TAR for the cyclopropane label at 120 DAT. M310I017 was found from 1 DAT onwards. It reached its maximum at 8 DAT with 7.0% TAR for both the benzyl and the cyclopropane label and was found in amounts of 0.9% TAR (benzyl label) and 1.1% TAR (cyclopropane label) at the end of incubation.

Formation of CO_2 (mineralization) was observed throughout the study reaching 8.7% TAR for the benzyl label and 7.4% TAR for the cyclopropane label after 120 days. No other volatile compounds were detected in significant amounts throughout the incubation period of 120 days.

Non-extractable radioactive residues (NER) were formed with maximum amounts of 31.9% TAR (benzyl label) and 15.1% TAR (cyclopropane label) after 120 days of incubation. The non-extractable radioactive residues were further characterized by fractionation into fulvic acids, humic acids, and humins. Upon extraction with NaOH roughly one fifth (cyclopropane label) to one third (benzyl label) of the NER were assigned to the humin fraction. The NaOH released radioactivity was attributed in a ratio of about 3:2 (benzyl label) and 2:3 (cyclopropane label) to the humic acid and the fulvic acid fraction, respectively.

Chiral analysis of selected extracts showed that both enantiomers of alpha-cypermethrin were degraded at a similar rate. The ratio between the two enantiomers of alpha-cypermethrin was only very slightly shifted towards the R-enantiomer over time.

Kinetic analyses and calculations of DT_{50} and DT_{90} values were performed following the recommendations of the FOCUS Kinetics workgroup. For alpha-cypermethrin, $DegT_{50}$ values accounted for 48.7 and 48.1 days, the $DegT_{90}$ values for 280.0 and 159.7 days for the benzyl (FOMC) and for the cyclopropane label (SFO), respectively. For the metabolite M310I017 the DT_{50} was calculated to 36.1 and 26.5 days, the DT_{90} to 120.0 and 169.3 days for the benzyl (SFO) and the cyclopropane label (FOMC), respectively. No decline was observed for the metabolites M310I001 and M310I011, and consequently no DT_{50} values could be derived from this study.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS code:	BAS 310 I (alpha-cypermethrin)
Reg. No.:	4078193
Chemical name (IUPAC):	racemate of (S)-cyano-3-phenoxybenzyl (1R,3R) 3 (2,2 dichlorovinyl)-2,2-dimethyl cyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S) 3 (2,2 dichlorovinyl) 2,2 dimethyl cyclopropanecarboxylate
Molar mass:	416.3033 g mol^{-1} (unlabeled)

Benzyl-label

Position of radiolabel:	benzyl-U-^{14}C
Specific radioactivity:	4.64 MBq mg^{-1}
Chemical purity:	93.4%
Radiochemical purity:	97.5% (radio-HPLC)
Batch No.:	775-0501

Cyclopropane-^{14}C-label

Position of radiolabel:	cyclopropane-1-^{14}C
Specific radioactivity:	4.7 MBq mg^{-1}
Chemical purity:	95.8%
Radiochemical purity:	98.9% (radio-HPLC)
Batch No.:	986-2015

Phenoxy-^{13}C-label

Position of radiolabel:	Phenoxy-1,2,3,4,5,6-^{13}C
Chemical purity:	95.1%
Batch No.:	1025-1034

Cyclopropane-^{13}C-label

Position of radiolabel:	cyclopropane-1-^{13}C
Chemical purity:	97.7%
Batch No.:	990-1024

2. Soil

The soil used (LUFA 5M) was a loamy sand soil (according to the German soil classification scheme DIN). After sampling from the field, the soil was allowed to dry at room temperature for one day and then sieved though a 2 mm sieve before use. After moistening to about 10 g per 100 g moist soil, the soil was stored at about 4°C. Prior to the application, the soil was acclimatized at ambient temperature, adjusted to a soil moisture of approximately 40% of the maximum water holding capacity (MWHC) and stored in the incubation chamber (20°C, dark) until application. The soil characteristics are summarized in Table 7.1.1.2-1.

Table 7.1.1.2-1: Characteristics of soil LUFA 5M

Designation	**LUFA 5M**
Origin	Mechtersheim, Rhineland-Palatinate, Germany
DIN particle size distribution [%]	
sand 0.063 – 2 mm	52.4
silt 0.002 – 0.063 mm	34.6
clay < 0.002 mm	13.0
textural class	loamy sand
USDA particle size distribution [%]	
sand 0.050 – 2 mm	59.7
silt 0.002 – 0.050 mm	27.4
clay < 0.002 mm	13.0
textural class	sandy loam
Total organic carbon [%]	2.03
CEC [$cmol^+ kg^{-1}$]	11.4
pH ($CaCl_2$) [-]	7.3
pH (H_2O) [-]	7.9
MWHC [g 100 g^{-1} dry soil]	27.0
Water retention at pF 2.0 [$g_{soil\ moisture}\ g^{-1}$ dry soil]	0.158
Water retention at pF 2.5 [$g_{soil\ moisture}\ g^{-1}$ dry soil]	0.150
Bulk density [kg L^{-1}]	1348
Microbial biomass [mg C 100 g^{-1} dry soil]	24.0

MWHC = Maximum water holding capacity

B. STUDY DESIGN

1. Experimental conditions

Generally, four applications were performed. Two applications with ^{14}C-benzyl-labeled and ^{14}C-cyclopropane-labeled test item were both performed at a nominal concentration of 0.3 mg a.s. per kg dry soil. To obtain samples allowing for the identification of unknown metabolites, soil was also treated at an exaggerated rate of about 3 mg test item per kg dry soil in additional experimental setups. The application solutions contained 1:1 mixtures of ^{14}C- and ^{13}C-labeled test item. Selected samples were worked up and the extracts subjected to LC-MS/MS for mass spectrometric identification of metabolites.

Prior to treatment with test item, the soil was checked for moisture content and re-adjusted to approximately 40% MWHC. Portions of 100 g soil (dry weight basis) were then filled into test vessels. The samples were incubated in the dark at a temperature of 20 ± 2°C and were connected to a continuous flow-through (CO_2-free synthetic air) system with traps for the collection of volatile organics (ethylene glycol and 0.5 M H_2SO_4) and CO_2 (0.5 M NaOH) during the aerobic phase of the incubation.

Test vessels containing the treated soil samples were switched to anaerobic conditions after 9 days of aerobic incubation by flooding each test vessel with 50 mL deionized water (forming a 1-2 cm water layer over the soils) and changing the flow-through gas to nitrogen instead of synthetic air. All incubation vessels were further kept in the dark at 20 ± 2ºC. During anaerobic incubation, the redox potentials (soil and water phases), the pH, and the dissolved oxygen in the water layer were determined at each sampling interval. Throughout the study, the water content of the soil was monitored periodically by weighing, and water was added when needed.

2. Sampling

Sampling times were 0 (no sampling of volatiles), 1, 3, 6, 8, 10, 14, 27, 45, 62, 90 and 120 days after treatment (DAT) for the soils treated at 0.3 mg a.s. kg^{-1} application rate.

At each sampling time two replicate vessels with soil were sampled (three replicate samples at 0, 62 and 120 DAT). At 10 DAT (benzyl label) and 1 DAT (cyclopropane label), reserve samples for were worked up like the regular samples. Moreover, at each sampling time except day 0, the flasks of the corresponding trapping system for volatiles were sampled as well and replaced with flasks containing fresh trapping solutions.

For the soils treated at the higher application rate of 3 mg a.s. kg^{-1} one replicate of each trial was sampled at 9, 35, 84 and 127 DAT. The trapping flasks were replaced as described above.

3. Description of analytical procedures

Aerobic incubation phase
Prior to work-up, the moisture of the samples was re-adjusted to the original content (close to pF 2.5). Soil samples were consecutively extracted with 4 x 100 mL acetonitrile/water (7/3, v/v) and 2 x 100 mL acetonitrile on a laboratory shaker (30 min). After each extraction step, the sample was centrifuged (15 min). Aliquots of each supernatant were measured by LSC.

Anaerobic incubation phase
For extraction during the anaerobic phase, the soil water slurry was extracted by adding acetonitrile to obtain an acetonitrile/water ratio of 1/1 (v/v). The slurry was extracted on a laboratory shaker for 30 min, the sample was centrifuged and the supernatant transferred into a 100 mL volumetric flask. Further extractions with 3 x 100 mL of acetonitrile/water (7/3, v/v) and 2 x 100 mL of acetonitrile followed. Aliquots of each extract were measured by LSC.

For HPLC, the acetonitrile/water and acetonitrile extracts were combined, concentrated to dryness by means of a rotary evaporator (40°C) and subjected to radio-HPLC.

To determine the amount of non-extractable residues, the extracted soil was dried in a drying oven at 60°C and aliquots thereof were combusted. The evolved $^{14}CO_2$ was measured by LSC.

The fraction of NER was further characterized by NaOH extractions (0.5 M NaOH, three times) of selected samples (from 3 DAT to 120 DAT). NaOH extracts were analyzed by LSC and processed to determine the distribution of radioactivity to the humin, humic, and fulvic acid fraction. The humic acid fraction and the fulvic acid fraction were analyzed by LSC. The fulvic acid fraction was further partitioned with ethyl acetate. Each ethyl acetate and water phase was measured by LSC. The ethyl acetate phases were combined, concentrated, and analyzed by LSC and HPLC. The remaining radioactivity in the soil residues was determined by combustion analyses (humin fraction). Further details are given in the report.

Aliquots of the ethylene glycol, 0.5 M H_2SO_4 or 0.5 M NaOH trapping solutions were subjected to LSC measurement.

Soil samples treated with an exaggerated rate of test item were worked up as described above for samples with a lower application rate. Combined soil extracts from 9, 35 and 84 DAT (benzyl-^{14}C- and phenoxy-^{13}C-labeled test item) and from 9 and 35 DAT (cyclopropane-^{14}C- and cyclopropane-^{13}C-labeled test item) were subjected to LC-MS/MS analysis.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints). Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values were performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006) "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 1.0, November 2011, 436 pp*].

The software package KinGUII (version 2.2014.224.1704) was used for parameter fitting [*SCHÄFER, D., MIKOLASCH, M., RAINBIRD, P., HARVEY, B. (2007)*; *WITT, J., GAO, Z., MEYER, H. (2014)*]. The error tolerance and the number of iterations of the optimization tool were set to 10^{-6} and 100, respectively.

For each data set, the kinetic models proposed by the FOCUS Kinetics guidance document were tested in order to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO), the Gustafson-Holden model (FOMC), and bi-exponential (DFOP) kinetics as already implemented in KinGUI. The Goodness-of-fit was evaluated by visual assessment, χ^2 minimum error, and type-I-error rate (t-test).

II. RESULTS AND DISCUSSION

A. TEST CONDITIONS

From 9 DAT to the end of the experiment the redox potential in the soil layer and the water phase of both experiments (exaggerated and lower rate) decreased continuously ranging from 161.6 to 270.9 mV at 9 DAT to a range of -178.7 to -350.8 mV at 120 DAT. The O_2 content in the water phase diminished quickly from 6.41/5.77 mg L^{-1} at 9 DAT to 0.34/0.50 mg L^{-1} at 10 DAT. The pH of the water phase increased during the experiment from 8.13/8.10 to 9.18 in both experimental setups. The development of these parameters demonstrated that anaerobic conditions were established during the experiment.

B. MASS BALANCE

Overall recovery of radiolabeled material averaged 94.1% TAR for the benzyl label and 98.7% TAR for the cyclopropane label. The distribution of radioactivity in extractable residues (ERR), non-extractable residues (NER), CO_2, and other volatiles is shown in Table 7.1.1.2-2 and Table 7.1.1.2-3.

C. EXTRACTABLE AND BOUND RESIDUES

The amount of extractable radioactive residues decreased from its initial percentage of > 99% TAR at 0 DAT to 51.4% TAR (benzyl label) and to 73.9% TAR (cyclopropane label) at 120 DAT. The decrease of the ERR can be mainly attributed to the aerobic phase of the incubation.

The different extractability in the two radiolabels was mirrored in the formation of non-extractable residues. Significant amounts of NER were formed in the soil treated with the benzyl label which increased continuously to 31.9% TAR after 120 days of incubation. In the samples treated with the cyclopropane label, lower amounts of NER were observed which increased to a maximum of 15.1% TAR at 120 DAT.

Table 7.1.1.2-2: Distribution of radioactivity and material balance after application of benzyl-U-^{14}C-labeled alpha-cypermethrin to soil LUFA 5M [% TAR]

D. VOLATILISATION

Formation of CO_2 (mineralization) was observed throughout the study reaching 8.7% TAR for the benzyl label and 7.4% TAR for the cyclopropane label after 120 days. Although mineralization was observed in both, the aerobic and the anaerobic phases of incubation, the formation of CO_2 markedly slowed down during the anaerobic phase. No other volatile compounds were detected in significant amounts throughout the incubation period of 120 days.

E. TRANSFORMATION OF PARENT COMPOUND

The summarized results of radio-HPLC analyses are presented in Table 7.1.1.2-4 and Table 7.1.1.2-5.

The extracted amount of parent compound decreased from 95.1% TAR and 99.5% at the beginning to 13.0% TAR and 11.1% TAR at 120 DAT with the benzyl and cyclopropane labels, respectively. The degradation was fast during the aerobic phase of the experiment, reaching 48.9% TAR for the benzyl label and 52.7% TAR for the cyclopropane label at 10 DAT. However, it slowed down during the anaerobic phase.

With each label, one prominent label specific metabolite was detected: M310I011 (3-PBA) with the benzyl label and M310I001 (DCVA) with the cyclopropane label. Both metabolites occurred already at 0 DAT, and their concentrations increased further until 120 DAT, seeming to reach a plateau. The concentration of M310I011 increased from 1.5% TAR at day 0 to 30.0% TAR at 120 DAT (end of incubation). The concentration of M310I001 increased from 0.9% TAR at day 0 to 55.6% TAR at 120 DAT. The label specific metabolite M310I013 was first detected at 27 DAT (benzyl label) and found in concentrations up to 2.2% TAR.

Two further metabolites were detected with both labels: M310I022 and M310I017. M310I022 was found from 62 DAT onwards with maximum amounts of 2.9% TAR (benzyl label) and 4.3% TAR (cyclopropane label) at 120 DAT. M310I017 was found from 1 DAT onwards. It reached its maximum at 8 DAT with 7.0% TAR for both the benzyl and cyclopropane label and was found in amounts of 0.9% TAR (benzyl label) and 1.1% TAR (cyclopropane label) at the end of incubation.

Exclusion of trans-isomers of cypermethrin

Selected extracts (benzyl and cyclopropane label; 0, 8, 62 and 120 DAT) were investigated using a second reverse-phase HPLC system for the presence of trans isomers of cypermethrin. No noticeable amounts of trans isomers of cypermethrin were detected in the soil extracts, i.e. no conversion of the cis isomers to trans isomers occurred in the soil. The detailed results are presented in the report.

Investigation of the isomerization of cis isomers

Alpha-cypermethrin is a mixture of two enantiomers. In order to investigate the ratio of enantiomers over time a chiral HPLC method was used to analyze soil extracts from 0, 8, 27, 62 and 120 DAT. The data showed that both enantiomers of alpha-cypermethrin were degraded at a similar rate. The ratio between the two enantiomers of alpha-cypermethrin was only very slightly shifted towards the R-enantiomer over time. The detailed results are presented in the report.

F. CHARACTERIZATION OF NON-EXTRACTABLE RESIDUES (NER)

From 3 DAT to 120 DAT, NER were further characterized by NaOH treatment and subsequent fractionation into fulvic acids, humic acids, and humins. Results are shown in Table 7.1.1.2-6 and Table 7.1.2.1.1-7.

Table 7.1.1.2-6: Characterization of non-extractable residues in soil treated with benzyl-U-^{14}C-alpha-cypermethrin [% TAR]

G. KINETIC MODELING RESULTS

The kinetic evaluation was performed according to FOCUS in order to derive trigger endpoints for alpha-cypermethrin and its degradation products. As a decline of residues was observed only for M310I017, it was the only metabolite which could be included in the kinetic evaluation. The kinetic analysis was based on the decline of the measured residues under anaerobic incubation conditions. Trigger endpoints for the metabolites M310I001 and M310I011 could not be estimated since no decline of the measured residues was observed.

The resulting $DegT_{50}$ and $DegT_{90}$ values for alpha-cypermethrin and the DT_{50} and DT_{90} values for M310I017 are summarized in Table 7.1.1.2-8 and Table 7.1.1.2-9.

Table 7.1.1.2-8: Trigger endpoints for alpha-cypermethrin

Compound	Label	Kinetic model	χ^2 error	$DegT_{50}$ [d]	$DegT_{90}$ [d]
Alpha-cypermethrin	Benzyl	FOMC	2.8	48.7	280.0
	Cyclopropane	SFO	2.9	48.1	159.7

Table 7.1.1.2-9: Trigger endpoints for metabolites of alpha-cypermethrin

Compound	Label	Kinetic model	χ^2 error	DT_{50} [d]	DT_{90} [d]
M310I017	Benzyl	SFO[a]	5.4	36.1	120.0

M310I011		-	-	Derivation of endpoints not possible	

[a] Evaluation of metabolite decline

III. CONCLUSION

Alpha-cypermethrin degraded fast under aerobic conditions followed by a slightly slower degradation under anaerobic conditions. Significant amounts of non-extractable radioactive residues were formed in the soil treated with the benzyl label which increased continuously to 31.9% TAR after 120 days of incubation. In the samples treated with the cyclopropane label, lower amounts of non-extractable radioactive residues were observed which increased to a maximum of 15.1% TAR at 120 DAT. $^{14}CO_2$ was formed in moderate amounts up to 8.7% TAR. No other volatile compounds were detected in significant amounts.

Several metabolites were formed. The most prominent label specific metabolites were M310I011 (benzyl label) and M310I001 (cyclopropane label) reaching 30.0% TAR and 55.6% TAR, respectively at the end of the study. The metabolites M310I017 and M310I022 were found with both labels at up to 7.0% TAR and 4.3% TAR, respectively.

Using a chiral HPLC method it was shown that both enantiomers of alpha-cypermethrin were degraded at a similar rate.

$DegT_{50}$ values for the benzyl and the cyclopropane labeled alpha-cypermethrin were calculated to be 48.7 and 48.1 days and $DegT_{90}$ values were estimated to be 280.0 and 159.7 days according to the best fit kinetics. For the metabolite M310I017, best fit kinetic calculations resulted in DT_{50} values of 36.1 and 26.5 days and DT_{90} values of 120.0 and 169.3 days. No decline was observed for the metabolites M310I001 and M310I011 and therefore no DT_{50} values could be derived from this study.

The RMS BE has asked for additional kinetic evaluations on 27. Oct. 2016. The results are presented and discussed below.

Report:	CA 7.1.1.2/1 Anonymous, 2016 a Response to RMS BE - Request concerning kinetic re-evaluations – Alpha-cypermethrin 2016/1324158
Guidelines:	none
GLP:	no

RMS: RMS notes that the Notifier performed a separate kinetic assessment for each label. In peer review, it is common practice to handle residuals from the same soil with different radiolabelled positions as replicate values. Please Notifier consider that residue data from two tested labels from the same soil need to be processed as replicates for the active substance and its metabolites.

BASF response: A kinetic evaluation was performed by processing the residue data of the two tested labels as replicates. The results are summarized in Table 7.1.1.2-10 and the corresponding Kingui fits are presented in Appendix 2 in the original response document. The endpoints (DT_{50} = 46.8 d, DT_{90} = 222 d, FOMC model) are comparable with those derived by performing a separate kinetic assessment for each label (geomean DT_{50} = 48.4 d, geomean DT_{90} = 211.5 d). Therefore, the endpoints presented in the dossier are considered adequate.

Table 7.1.1.2-10: Statistical and visual assessment of kinetic models for degradation of alpha-cypermethrin in soil under anaerobic condition

Kinetic model	χ^2 [%]	p (t-test)	Visual assessment	$DegT_{50}$ [d]	$DegT_{90}$ [d]
SFO	3.0	k: <0.01	good	51.4	170.7
FOMC	1.9	β: <0.1	good	46.8	222.0
DFOP	2.0	k1: <0.01 k2: <0.01 g: <0.01	good	46.6	191.6

CA 7.1.1.3 Soil photolysis

Studies already submitted and peer reviewed:

1. Takahashi N. (1985), Photodegradation of the pyrethroid insecticide cypermethrin in water and on soil surfaces
Photodegradation of cypermethrin was investigated on three Japanese soils using cypermethrin labelled in the cyclopropyl- the cyano- and the benzyl position. Treated soils were exposed to natural sunlight for 7 days. No balance could be obtained and the soils were drying during the experiment, so that an influence on metabolite degradation could not be excluded. The study was not conducted according to OECD guideline and examples of raw data are missing. Though a lot of effort was undertaken, the study should not be included in the evaluation.

2. Hall, J.S. et al. (1981) Cypermethrin: Photodegradation on a soil surface
The test was carried out with mixtures of cis and trans cypermethrin isomers. Treated soil plates were exposed to natural sunlight during fine weather periods and protected with a polythene shelter during rainfall. The shelter allowed the transmission of UV radiation from sunlight. The study was rejected because of its poor quality in the evaluation.

3. Van Dijk A. et al. (1993) ^{14}C- Alpha-cypermethrin: Study of its photodegradation on soil
The study was performed with alpha-cypermethrin labelled in the benzyl ring only. The treated soil was exposed to artificial sunlight (wavelength above 290 nm) for 30 days during a 12 hour day and night cycle. Dark control samples were also analysed. The irradiated samples showed a DT_{50} of 31 days compared to 193 days of the dark control. The main metabolite detected was 3-PBA with traces of 3-PBAldehyde.

Table 7.1.1.3-1: List of soil photolysis studies in soil performed with (alpha-) cypermethrin

DocID	Parent compound	Soil	Application rate [mg kg^{-1}]	Incubation temperature	Irradiation period [hours]	Remark
CY-905-038	Cypermethrin	Light clay Sandy loam Sandy clay loam	1.1 µg/cm³	outside temperature	1 month (natural sunlight)	Takahashi et al. 1985 Literature

GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Report:	CA 7.1.1.3/2 Hassink J., 2015 b Report Amendment No. 1 - Soil photolysis of BAS 310 I 2015/1107645
Guidelines:	EPA 161-3, EPA 835.2410, Draft OECD Guideline: Phototransformation of Chemicals in Soil Surfaces (Jan. 2002), SETAC Procedures for assessing the environmental fate and ecotoxicity for pesticides (March 1995)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

The amendment to the report contains KinGUI graphs of the parameter estimation section that were missing in the final report.

Executive Summary

A soil photolysis was conducted with cyclopropane-1-^{14}C-labeled-alpha-cypermethrin (cyclopropane label) and benzyl-^{14}C-labeled-alpha-cypermethrin (benzyl label) to investigate their behavior in soil under the influence of light.

The overall mean values for the material balance in the photolysis and the dark control were in the range of 95.1 - 118.8% of the total applied radioactivity (TAR). Carbon dioxide was the only volatile degradation product trapped. It reached 5.4% TAR after 15 days in the photolysis test and 7.6% TAR in the dark control for the cyclopropane label. For the benzyl label, it reached 1.9% TAR after 15 days in the photolysis test and 6.7% TAR in the dark control.

The sample extractability for the photolysis test differed from the dark control. At the end of the study, 15.0% TAR and 10.8% TAR of the cyclopropane and benzyl label, respectively, were not extractable from the illuminated soil samples.. At the end of the incubation of the dark control samples, about 12.4% TAR and 17.3% TAR of the cyclopropane and benzyl label, respectively, were non-extracted. The alkali-soluble radioactivity amounted to 11% TAR 15 days after treatment (DAT) in the photolysis and was further fractionated to distinguish between acid-insoluble humic acids and acid-soluble fulvic acids. The major part of the radioactivity could be assigned to the fulvic acid fraction (max. 8.4% TAR at 15 DAT for the cyclopropane label and 4.6% TAR at 15 DAT for the benzyl label). In the dark control samples, the amount of non-extractable residues reached 12.4% TAR and 17.3% TAR for the cyclopropane label and the benzyl label, respectively, after 15 days. It was confirmed that the alkali-soluble fraction consisted of radioactive material mainly assigned to the fulvic fraction (6.1% TAR at 15 DAT for the cyclopropane label and 5.9% TAR for the benzyl label).

The concentration of the cyclopropane label declined to 65.5% TAR in the course of the photolysis experiment under continuous irradiation and to 74.5% TAR in the dark control samples. The concentration of the benzyl label declined in the photolysis experiment to 64.1% TAR within 15 days and to 55.7% TAR in the dark control samples.

Aliquots of all samples were analyzed by radio-HPLC. One metabolite was observed in the photolysis study with the cyclopropane label as well as in the corresponding dark control samples. It accounted for 5.4% TAR at 15 DAT in the irradiated samples and reached a maximum of 10% TAR at 10 DAT in the dark control samples. This metabolite was also observed in the aerobic soil metabolism study [*CA 7.1.1.2, BASF DocID 2014/1000641*], and was identified by MS measurement as DCVA. Structure elucidation is fully described in the final report of the aerobic soil metabolism study. No other degradation products with more or equal 5% TAR occurred in the photolysis and the dark controls. No modification of the enantiomeric ratio and no formation of the trans isomer of alpha-cypermethrin were observed during the study.

Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values (non-GLP) for alpha-cypermethrin in soil was performed following the recommendations of the FOCUS Kinetics workgroup. The analysis was conducted by non-linear regression methods employing the software tool KinGUII. The following $DegT_{50}$ and $DegT_{90}$ values used as trigger endpoints were calculated (Table 7.1.1.3-2).

Table 7.1.1.3-2: **Trigger endpoints for alpha-cypermethrin**

Test system	Label	Best-fit model	χ^2 error	Trigger endpoints	
				$DegT_{50}$ [d]	$DegT_{90}$ [d]
Irradiated	Cyclopropane-1-^{14}C	SFO	3.2	29.7	98.6
	Benzyl-^{14}C-label	DFOP	3.7	27.6	119.8
Dark control	Cyclopropane-1-^{14}C	SFO	4.1	30.9	102.6
	Benzyl-^{14}C	DFOP	5.0	No reliable endpoints derived	

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS-Code:	BAS 310 I (alpha-cypermethrin)
Registry No.:	4078193
Chemical name:	Racemate of (S)-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Molecular formula:	$C_{22}H_{19}CI_2NO_3$
Molar mass:	416.3 g mol^{-1} (unlabeled)

Label 1 (cyclopropane label)

Label:	cyclopropane-1-^{14}C
Batch No.:	986-1046
Specific activity of a.s.:	4.9 MBq mg^{-1}
Radiochemical purity:	98.2%
Chemical purity:	93.6%

Label 2 (benzyl label)

Label:	benzylring-U-^{14}C
Batch No.:	775-0401
Specific activity of a.s.:	4.94 MBq mg^{-1}
Radiochemical purity:	96.1%
Chemical purity:	93.7%

2. Soil

The study was conducted with two soil samples classified as sandy loam (USDA) and originated from the Landwirtschaftliche Untersuchungs- und Forschungsanstalt (LUFA) Speyer, South Western Germany. The sampling depth was 0-20 cm. The soil was passed through a 2 mm sieve, remoistened to approximately 8-12% soil moisture and then stored at about 4°C in the dark no longer than three months before use. An overview of the soil parameters is listed in Table 7.1.1.3-3.

Table 7.1.1.3-3: Characteristics of soil LUFA 5M used for soil photolysis study with ^{14}C-alpha-cypermethrin

Soil designation	**LUFA 5M 12/1651/04** Germany (Origin LUFA Speyer)	**LUFA 5M 12/1651/05** Germany (Origin LUFA Speyer)
DIN 4220 Particle size distribution [%]		
sand 0.063 – 2 mm	52.4	54.1
silt 0.002 – 0.063 mm	34.6	31.7
clay < 0.002 mm	13.0	14.2
textural class	loamy sand	loamy sand
USDA Particle size distribution [%]		
sand 0.050 – 2 mm	59.7	58.4
silt 0.002 – 0.050 mm	27.4	27.4
clay < 0.002 mm	13.0	14.2
textural class	sandy loam	sandy loam
Organic C [%]	2.03	2.18
pH [H_2O]	7.9	8.0
pH [$CaCl_2$]	7.3	7.4
cation exchange capacity [$cmol^+ kg^{-1}$]	11.4	8.8
Max. water holding capacity [g $100g^{-1}$ dry weight]	27.0	26.2
microbial biomass (start of study) [mg C $100g^{-1}$ dry soil]	24.0	31.1

B. STUDY DESIGN

1. Experimental conditions

Twelve and ten small steel dishes (approximately 8.8 cm x 4.3 cm x 1.2 cm) were filled with soil for photolysis test and for dark control, respectively. The dishes, which were later treated with the test item, were arranged in a rectangular bowl with a connected thermostat. The temperature of the dishes used for photolysis was adjusted and controlled by an external unit (22°C ± 1°C) while the dishes for dark control were put into an incubator at 22°C ± 1°C. The light intensity for the photolysis test group was set to 3 mW cm^{-2} (UVA range).The bowl was closed airtight with a quartz glass covering and the whole incubation device was continuously aerated with CO_2-depleted (0.5 M NaOH) and remoistened air via an air inlet and outlet.

In order to trap potentially evolving volatiles (including $^{14}CO_2$) the emergent air was bubbled through three different trapping solutions located between dish and pump: 1. NaOH (0.5 M); 2. ethylene glycol; 3. H_2SO_4 (0.5 M).

The incubation bowl for photolysis was placed under a SUNTEST CPS plus (Atlas) equipped with a Xenon lamp emitting light with a sunlight similar spectrum at a light intensity of about 3 mW cm^{-2} (UVA range). This corresponds to a clear summer day in Southern Germany (about 49°N). Wavelengths < 290 nm were filtered off to simulate natural sunlight.

To maintain the temperature especially on the quartz glass surface in order to avoid a rapid drying of the soil surface, the air space between lamp and quartz glass within the SUNTEST device was cooled by an external apparatus (Yeti, Seveso). To maintain the initial water content as constant as possible, dishes were weighed at each incubation day and the evaporated water was replaced.

The amount of test item to be applied on the soil surface was calculated based on the field application rate of 30 g ha^{-1}. If a soil layer of 1 cm and bulk density of 1.5 kg L^{-1} is assumed, the application rate corresponds to about 0.2 mg test item kg^{-1} dry soil. Because of the low specific radioactivity of the test items and to ensure a better detection of possible degradation products, the amount of test item applied was increased to 0.3 mg test item per kg dry soil, which corresponds to 9 µg of test item per dish.

2. Sampling

The sampling dates were 0, 1, 3, 7, 10 and 15 days after treatment (DAT). Two vessels were taken at each sampling time from each photolysis test system and the dark control (with exception of DAT 0, where no dark control samples were taken). At each sampling time, the respective volatile trapping solutions were removed.

3. Description of analytical procedures

Each soil sample was consecutively extracted four times with 40 mL of acetonitrile/water (7:3, v/v) by mechanical shaking for 1 h. After each extraction step, solid and extract were separated by centrifugation and filtered. The four corresponding extracts were combined and measured by liquid scintillation counting (LSC).

After the last acetonitrile/water extraction, the soil residues were air-dried and homogenized by milling. Aliquots of each sample were combusted in a sample oxidizer. Trapped $^{14}CO_2$ was analyzed by LSC.

All extracts were analyzed by radio-HPLC to determine the metabolite pattern. Prior to injection, the solvent of the extracts was completely evaporated by a rotary evaporator at 35°C. Then the residues were redissolved in a defined volume of the respective extraction solvent and subjected to HPLC analysis. Separation of cis and trans isomers, as well as enantiomers of alpha-cypermethrin was performed on two separate HPLC systems.

Non-extractable residues (NER) were found in amounts of 5-10% TAR at sampling days 3, 7, 10, and 15 in the photolysis experiment. The NER were further characterized by NaOH extraction. Samples were extracted three times with 0.5 M NaOH on a rotary shaker (270 rpm) and twice washed with water. Aliquots of the NaOH and the water extracts were analyzed by LSC. NaOH extracts and water extracts were pooled, representing together the fulvic and humic acid fraction.

Acidic precipitation (pH 1) of the humic acids from the pooled extracts was performed. After centrifugation, supernatants (fulvic acids) were analyzed by LSC. The precipitates were redissolved and measured by LSC.

The remaining soil samples after NaOH and water extraction were air-dried at room temperature, aliquots were combusted, and the formed $^{14}CO_2$ was trapped and analyzed by LSC to determine the ^{14}C residues in the humin fraction.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints). Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values was performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006)*]. The software package KinGUII (version 2.2014.224.1704) was used for parameter fitting [*Witt et al. (2014)*]. The error tolerance and the number of iterations of the optimization tool were set to 0.00001 and 100, respectively.

For each data set, the kinetic models proposed by the FOCUS Kinetics guidance document were tested to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO) and the Gustafson-Holden model (FOMC), are already implemented in KinGUI. The Goodness-of-fit was evaluated by visual assessment, χ^2 minimum error, and type-I-error rate (t-test) [for details see *Chapter 6.3 in FOCUS (2006)*].

Replicate measurements were considered for the parameter estimation. The initial concentration of the applied test item was set to the material balance recovered at day 0. The χ^2 value was calculated for the kinetic model as recommended by FOCUS, considering the average of replicate measurements. For the individual parameters, the t-test statistics were based on number of individual measurements.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

Total recoveries of radioactivity extracted from soil are summarized in Table 7.1.1.3-4 and Table 7.1.1.3-5. The overall values for the mean mass balance in the photolysis and in the dark control were for both labels in the range of 95.1 - 118.8% TAR.

Table 7.1.1.3-4: Material balance and distribution of radioactivity for the photolysis and the dark control test with cyclopropane-1-^{14}C-labeled alpha-cypermethrin [% TAR]

B. EXTRACTABLE AND BOUND RESIDUES

For the cyclopropane label, the amount of extractable radioactive residues (ERR) decreased to 92.6 and 90.6% TAR after 15 days of incubation (photolysis and dark control, respectively). For the benzyl label, the amount of ERR decreased to 87.4 and 71.2% TAR after 15 days of incubation (photolysis and dark control, respectively).

For the cyclopropane label, the amount of non-extractable residues (NER) increased from 1.7% TAR on day 0 to 15.0% TAR in the photolysis compared to 12.4% TAR in the dark control after 15 days. For the benzyl label, the amount of NER increased from 1.9% TAR on day 0 to 10.8% TAR in the photolysis compared to 17.3% TAR in the dark control after 15 days.

C. VOLATILIZATION

Carbon dioxide was the only trapped volatile degradation product. After 15 days of treatment, 5.4% TAR and 1.9% TAR of the cyclopropane- and benzyl-labeled test item, respectively, were detected in the photolysis experiments and 7.6% TAR and 6.7% TAR were detected in the dark controls. In sulfuric acid and ethylene glycol no significant radioactivity could be measured at any time.

D. TRANSFORMATION OF PARENT COMPOUND

Aliquots of all sample extracts were analyzed by radio-HPLC (see Table 7.1.1.3-6 and Table 7.1.1.3-7).

After 15 days, the amount of cyclopropane label decreased to 65.5% TAR in the photolysis and to 74.5% TAR in the dark control experiment. The benzyl label decreased to 64.1%TAR in the photolysis and to 55.7% TAR in the dark control experiment.

Several degradation products were detected in the extracts, but only 3-(2,2-dichlorovinyl)-2,2-dimethyl cyclopropanecarboxylic acid (DCVA) appeared in amounts higher than 5% TAR in extracts of soil samples treated with the cyclopropane label. It was found up to 5.4% TAR in irradiated conditions and up to 10% TAR in the dark control. All other degradation products never exceeded 5% TAR.

The identity of DCVA was confirmed by chromatographic comparison with the retention time of the reference item Reg. No. 180011 in the aerobic soil metabolism study [*CA 7.1.1.2, BASF DocID 2014/1000641*], in which DCVA was also detected in extracts of soil samples also treated with the cyclopropane labeled test item. Verification of the identification of DCVA was obtained by mass spectrometry in the mentioned study.

DAT = Days after treatment
* Individual peaks < 5.0%TAR
** Day 0 samples of the dark control are the day 0 samples of the photolysis test

Throughout the study, only one peak was observed in the chromatograms obtained by the isomer selective HPLC system. This confirms that no trans isomers were formed during the photolysis study.

Additionally, no change of the enantiomeric ratio could be observed during the study, irrespective of the radiolabel.

F. KINETIC MODELING RESULTS

The calculated $DegT_{50}$ and $DegT_{90}$ values of alpha-cypermethrin used as trigger endpoints are given in Table 7.1.1.3-8. For the metabolite DCVA no reliable endpoints could be derived.

Table 7.1.1.3-8: Trigger endpoints for alpha-cypermethrin

Test system	Label	Best-fit model	χ^2 error	Trigger endpoints	
				$DegT_{50}$ [d]	$DegT_{90}$ [d]
Irradiated	Cyclopropane-^{14}C	SFO	3.2	29.7	98.6
	Benzyl-^{14}C	DFOP	3.7	27.6	119.8
Dark control	Cyclopropane-^{14}C	SFO	4.1	30.9	102.6
	Benzyl-^{14}C	DFOP	5.0	No reliable endpoints derived	

III. CONCLUSION

Irradiation in the soil photolysis experiment with cyclopropane-1-^{14}C-labeled-alpha-cypermethrin and benzyl-^{14}C-labeled alpha-cypermethrin did not show an influence of sunlight on the degradation behavior and metabolite formation in soil. The known metabolite DCVA was observed in the soil samples treated with the cyclopropane-^{14}C-labeled alpha-cypermethrin, both, in the irradiated samples and in the dark controls.

The RMS BE has asked for additional kinetic evaluations on 27. Oct. 2016. The results are presented and discussed below.

^{14}C alpha-cypermethrin: study of its photodegradation on soil (Van Dijk *et al.*, 1993) BASF DocID: AL-620-010

RMS: Please Notifier perform a kinetic assessment according to FOCUS kinetics guidance document (2006) for the data from Van Dijk.

BASF response: A kinetic evaluation was performed according to FOCUS kinetics guidance document (2006) for the data from Van Dijk et al. (1993). The results are summarized in Table 7.1.1.3-9 and Table 7.1.1.3-10 and the corresponding Kingui fits are presented in Appendix 3 in the original response document. The endpoints (DT_{50}: 34.1 and 177.9 d for irradiated and dark control test system, SFO model) are comparable with those derived in the original study (DT_{50}: 31 and 193 d for irradiated and dark control test system). For this reason and taking into account that kinetic evaluation according to FOCUS is not formally required for soil photolysis studies, the endpoints of the original study are considered still valid.

Table 7.1.1.3-9: Statistical and visual assessment of kinetic models for soil photolysis of alpha-cypermethrin, irradiated test system

Kinetic model	χ^2 [%]	p (t-test)	Visual assessment	$DegT_{50}$ [d]	$DegT_{90}$ [d]
SFO	5.5	k: < 0.01	acceptable	34.1	113.3
FOMC	6.0	β: < 0.01	acceptable	34.1	113.3
DFOP	6.9	k1: < 0.01 k2: < 0.05 g: < 0.01	acceptable	34.1	113.3

CA 7.1.1.3/1 Michel, A., Hassink, J. (2014b). "Soil Photolysis of BAS 310 I". BASF DocID: 2014/1000642

RMS: RMS notes that the Notifier performed a separate kinetic assessment for each label. In peer review, it is common practice to handle residuals from the same soil with different radiolabelled positions as replicate values. Please Notifier consider that residue data from two tested labels from the same soil need to be processed as replicates, and please Notifier perform a new kinetic assessment.

BASF response: A kinetic evaluation was performed by processing the residue data of the two tested labels as replicates. The results are summarized in Table 7.1.1.3-11 and Table 7.1.1.3-12 and the corresponding Kingui fits are presented in Appendix 4**Fehler! Verweisquelle konnte nicht gefunden werden.** in the original response document. The endpoints (DT_{50}: 26.9 and 25.1 d for irradiated and dark control test system, SFO) are comparable with those derived by performing a separate kinetic assessment for each label (geomean DT_{50}: 28.6 d for irradiated test system; DT_{50}: 30.9 d for dark control test system). Therefore, the endpoints presented in the dossier are considered adequate.

CA 7.1.2 Rate of degradation in soil

CA 7.1.2.1 Laboratory studies

The studies listed in Table 7.1.2.1-1 were evaluated and peer reviewed in the registration process.

1. Andre (1989): Versuchsbericht zum Verbleib von Pflanzenschutzmitteln in Boden gemäß BBA-Richtlinien Teil IV, 4-1

Andre (1990a) Determination of the stability of Cyperkill 40 in a sand soil and

Andre (1990b) Determination of the stability of Cyperkill 40 in a loamy sand soil

The three trials reported by Andre 1989, 1990a and 1990b were submitted by Mitchell Cotts and are available for BASF. The studies were not conducted with alpha-cypermethrin but with a mixture of cis and trans isomers that were separately quantified. The application rates a highly exaggerated (6 kg a.s. ha^{-1} more than 100 fold overdosed) and not agricultural soils were used, but forest soils. Therefore these studies are not considered suitable for the determination of the DT_{50} of alpha-cypermethrin.

Table 7.1.2.1-1: List of laboratory degradation studies in soil performed with (alpha-) cypermethrin

DocID	Parent compound	Soil	Application rate [mg kg^{-1}]	Incubation temperature	Incubation period [days]	Remark
Andre, 1989, 1990a, 1990b	Cypermethrin	Sandy loam Sand Loamy sand	8.0	20-22°C		Submitted by Mitchell Cotts
AL-620-008	Cypermethrin; mixture of all cis isomers of cypermethrin; mixture of all trans isomers of cypermethrin	Sandy clay Sandy loam Clay	2.5	25±2°C (aerobic and anaerobic)	160	Standen 1976
AL-620-013	Alpha-cypermethrin	Sandy loam	0.3 1.5	10±2°C 20±2°C 20±2°C	120	Gedik, Keirs 2001

2. The degradation of the insecticide WL 43467 in soil under laboratory conditions (Standen 1976 AL-620-008, published by Roberts 1977, AL-905-062)
In this study, the degradation of cypermethrin and its isomers WL 43481 (both cis isomers) and WL 42641 (both trans isomers) were studied in three soils, two from Spain and one UK soil. The study of Standen (1976) was also submitted in the application for zeta-cypermethrin. These were evaluated by EFSA (EFSA Scientific Report (2008) 196, 1-119) and it was concluded that these studies should not be relied on for regulation. In the study no material balance is available, as no volatiles were trapped and samples were only taken at 4 intervals.
3. Gedik L. and Keirs D.C. (2001) [^{14}C]-Alpha-cypermethrin (BAS 310 I): Degradation in soil under aerobic conditions
This study was peer reviewed but a kinetic re-evaluation and an amendment describing the attempt for the identification of an unknown metabolite of the study were performed for this submission. Therefore the study will be resubmitted.

CA 7.1.2.1.1 Aerobic degradation of the active substance

Report:	CA 7.1.2.1.1/1 Gedik L.,Keirs D.C., 2001 a [14C]-Alphacypermethrin (BAS 310 I): Degradation in soil under aerobic conditions AL-620-013
Guidelines:	EEC 91/414 Annex II 7.1.1.1.1, SETAC Europe Part 1 Section 1.1 (March 1995), EEC 95/36 of 14 July 1995 amending 91/414/EEC, OECD Draft Guideline for aerobic and anaerobic transformation in soil (October 1999)
GLP:	yes (certified by United Kingdom Department of Health, UK)

Executive Summary

The objective of this study was to investigate the rate of breakdown of ^{14}C-alpha-cypermethrin in a sandy loam soil under aerobic conditions at two temperatures (20°C and 10°C). The rate of evolution of volatiles and the profile of degradation products was also investigated.

A freshly collected sample of a typical agricultural soil was obtained from within the UK for use on the study. Soil samples were treated with ^{14}C-alpha-cypermethrin at a rate equivalent to 0.307 mg kg^{-1} soil. The maximum anticipated field application rate for alpha-cypermethrin is 30 g a.s. ha^{-1} equivalent to 0.03 mg kg^{-1}. However, as the specific activity of alpha-cypermethrin was low, the application rate was increased to 0.3 mg kg^{-1} in order to facilitate the detection of alpha-cypermethrin and its degradation products. The samples were incubated in the dark at a soil moisture of 50% of the maximum water holding capacity and a temperature of 20 ± 2°C (Group A) or 10 ± 2°C (Group B) for up to 120 days under aerobic conditions. Ethanediol and sodium hydroxide were used to collect non-specific volatiles and $^{14}CO_2$, respectively. Traps were sampled and replenished at regular intervals throughout the study. Duplicate samples were collected for analysis of total radioactivity at zero time (immediately after application of test substance) and at 3, 7, 14, 28, 42, 70 and 120 days of incubation. Samples were extracted with acetonitrile : water (70:30, v/v) and analyzed by HPLC.

The mean overall recovery of applied radioactivity ranged from 93% to 103% other all samples. The total levels of solvent extractable radioactivity declined over the incubation period in both groups from a maximum of 98% of the total applied radioactivity (TAR) at zero time to 12% at day 120 at 20°C and from 100% to 36% TAR at 10°C. As the total levels of extractable radioactivity decreased with time, concomitant increases of $^{14}CO_2$ and non-extractable residues were observed over the course of the study. These accounted for 51% and 37% TAR, respectively at study termination at 20°C and 32% and 34% TAR at 10°C. Radioactivity recovered in the ethanediol traps and apparatus washings were low (less than 1% TAR).

Following extraction, the organic matter from day 120 samples incubated at both temperatures was fractionated into humin, fulvic acid, and humic acid. The radioactivity associated with the humin, fulvic acid, and humic acid accounted for means of 19, 5 and 6% TAR in soil samples incubated at 20°C, respectively. The corresponding values in soil samples incubated at 10°C were 17, 6 and 6% TAR.

The test item was rapidly degraded at each temperature. Alpha-cypermethrin quantitatively accounted for the TAR at zero time and these levels subsequently decreased to a mean of 7.5% at 20°C and 26.7% TAR at 10°C at day 120.
Low levels of CL 206128 (3-PBA), three unknown components, and polar material were also extracted from the soil. Two other minor unknown components (<1% TAR) were associated with the fulvic acid fraction of the organic matter extracted from Group B samples.

In addition to parent compound, low levels of CL 206128 (3-PBA) were detected in samples at day 7 in both groups accounting for less than 9% TAR. A minor unknown component, designated A, was detected in all samples after day 3. At 20°C, levels of this component accounted for a maximum of 5.1% TAR in a single day 7 replicate (mean value of 4.9% TAR) and subsequently decreased to a mean value of 1.7% TAR at study termination. Unknown A accounted for a maximum of 8.1% TAR in a single 10°C replicate at day 14 and decreased to a mean value of 5.3% TAR at day 120. Two other minor components, designated B and C, and polar material were detected at intervals throughout the incubation period in both groups each accounting for less than 5% TAR.

HPLC analysis of the fulvic acid fractions following fractionation of the organic matter indicated the presence of a polar component in samples from both groups. Two minor components, designated D and E, were also detected in the samples from Group B accounting for less than 1% TAR. Alpha-cypermethrin was not detected in any of the fulvic acid fractions.

At the time of study conduction, the rate of degradation of alpha-cypermethrin was calculated using ModelMaker v 4.0 assuming simple first-order or biphasic first-order kinetics. The DT_{50} and DT_{90} values for the degradation of alpha-cypermethrin in soil incubated at 20°C were estimated as 19 - 20 and 68 - 104 days, respectively. The corresponding values for soil incubated at 10°C were 50 - 55 and 183 - 233 days, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS code:	BAS 310 I (alpha-cypermethrin)
Reg.No.:	4078193
Chemical name (IUPAC):	A racemate comprising (S)-α-cyano-3-phenoxybenzyl(1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-α-cyano-3-phenoxybenzyl(1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Molecular weight:	416.32 g mol^{-1} (unlabeled)

Radio-labeled alpha-cypermethrin

Position of radiolabel:	Benzyl-ring-U-^{14}C
Specific radioactivity:	84.5 µCi mg^{-1}
Radiochemical purity:	99.5% (according to certificate)

97.7% (determined by radio-HPLC)
99.1% (determined by radio-TLC)

Carbon-13 labeled alpha-cypermethrin

Position of radiolabel:	Benzyl-ring-U-^{14}C / benzyl-7-^{13}C
Specific radioactivity:	27.04 µCi mg^{-1}
Radiochemical purity:	98.08% (according to certificate)

2. Soils

Top-soil samples (0-20 cm) of typical agricultural soil were used for treatment and incubation. The soils were sieved through a 2 mm sieve before use, remoistened to approximately 50% of the maximum water holding capacity, and stored in the dark at about 4°C. The soil characteristics are summarized in Table 7.1.2.1.1-1.

Table 7.1.2.1.1-1: Soil properties of soil used to investigate degradation rate of ^{14}C-alpha-cypermethrin

Soil designation	Ipswich (Levington Soil Code PT190; Inveresk Soil Code S332)
Origin	Ipswich, UK
UK Particle size distribution [%]	
Sand 0.060 – 2 mm	65.8
Silt 0.002 – 0.060 mm	26.9
Clay < 0.002 mm	7.3
Textural class	Sandy loam
USDA Particle size distribution [%]	
Sand 0.050 – 2 mm	66.6
Silt 0.002 – 0.050 mm	26.7
Clay < 0.002 mm	6.7
Textural class	Sandy loam
Total organic carbon [%]	0.9
pH (KCl)	6.5
Cation exchange capacity [meq/100g dry soil]	9.7
Maximum water holding capacity [%]	42.2
Microbial biomass (initial) [mg C/100g dry soil]	25.8
Microbial biomass at 20°C[mg C/100g dry soil]	20.3
Microbial biomass at 10°C [mg C/100g dry soil]	27.4

B. STUDY DESIGN

1. Experimental conditions

The soils were treated with ^{14}C-labeled alpha-cypermethrin at a nominal concentration of 0.307 mg kg^{-1} dry soil. After treatment, the soil in the test vessels was carefully shaken by hand in order to distribute the test item as homogeneously as possible within the soil. 100 g soil portions (dry weight equivalents) were prepared including duplicate samples at each sampling point.

The test vessels were incubated in the dark for up to 120 days at a temperature of either 20 ± 2°C (Group A) or 10 ± 2°C (Group B). Throughout the incubation period, the test vessels were continuously aerated with a slight stream of moistened, CO_2-free air. The outgoing air was led through a series of three gas-washing bottles. The first trap was a safety trap to prevent back flow, the remaining two contained trapping solutions for potential volatiles (ethanediol and 0.5M NaOH). Soil moisture was maintained at about 50% of the maximum water holding capacity for the duration of the study.

For the determination of the microbial biomass, extra test vessels with untreated soil treated with 100 µL acetonitrile and incubated as described above.

2. Sampling

Duplicate samples were taken at 0, 3, 7, 14, 28, 42, 70 and 120 days after treatment (DAT). Traps were sampled weekly up to 49 days and at each sampling occasion. Traps were also sampled at 98 days.

3. Description of the analytical procedures

The soil samples were extracted consecutively four times with about 100 mL acetonitrile : water (70:30, v/v) by shaking for about one hour.

After each extraction step, the suspension was centrifuged, the supernatant was filtered, and aliquots of each solution were radio-assayed. After removal of samples from flasks, flasks were soaked in acetone to remove any residual radioactivity. Aliquots of each apparatus wash were submitted for liquid scintillation counting (LSC).

Aliquots (about 25% by volume) of each extract were combined, concentrated, and analyzed by LSC as well as HPLC for the characterization of ^{14}C alpha-cypermethrin and its degradation products. TLC analysis of selected concentrated extracts was performed for confirmatory purposes. Procedural recoveries for sample concentration were in the range of 89 to 102% of the total applied radioactivity (TAR).

The extracted soil was dried at room temperature and aliquots were combusted to determine the amount of non-extractable radioactive residues (NER). Combustion products were trapped in Carbosorb mixed with Permaflour E+ scintillator and measured by LSC.

Trap solution aliquots and apparatus wash aliquots were analyzed by LSC as well. To confirm the presence of $^{14}CO_2$ in the trap samples, the radioactivity associated with the sodium hydroxide traps from a single soil sample from day 120 was precipitated as barium ^{14}C-carbonate. The radioactive content of the supernatant was then determined by LSC.

The organic matter from the 120 day extracted residues was exhaustively extracted, twice with 0.5 M NaOH by shaking and sonication. After centrifugation, radioactivity of the residue (humin fraction) was determined by combustion analysis. The humic acid fraction in the NaOH extracts was precipitated by acidification (pH 1) using concentrated HCl. After centrifugation, the supernatant (fulvic acid fraction) was removed. Both, the humic and the fulvic acid fractions were analyzed by LSC. The fulvic acid fractions were further analyzed by HPLC. All samples were stored at -20°C in a freezer.

4. Calculation of the degradation rate of alpha-cypermethrin

At the time of study conduction the DT_{50} and DT_{90} values for alpha-cypermethrin in the aerobic soil systems at 20°C and 10°C were calculated based on first-order kinetics. Two mathematical compartment models were developed using ModelMaker v 4.0 to describe the observed data with simple first-order kinetics (SFO) and biphasic first-order kinetics (DFOP). An actual kinetic evaluation of the study data following FOCUS recommendations [*FOCUS (2006)*] can be found in section CA 7.1.2.1.1/3 [*BASF DocID 2014/1159505*].

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the extractability of radioactive residues in the soils are presented in Table 7.1.2.1.1-2 and Table 7.1.2.1.1-3. The average material balance ranged from 93% to 101% TAR in soil samples incubated at 20°C and from 95% to 103% TAR in soil samples incubated at 10°C.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in extractable residues (ERR), non-extractable residues (NER), CO_2, and other volatiles is shown in Table 7.1.2.1.1-2 and Table 7.1.2.1.1-3, respectively. The total levels of extractable radioactivity (ERR) declined over the incubation period from a mean of 97.6% TAR at zero time to 12.2% TAR at 120 DAT (20°C) and from 99.8% to 36.1% TAR (10°C), respectively.

The level of NER increased during the study from about 0.7% TAR at zero time to about 36.8% TAR at 120 DAT in samples incubated at 20°C and from about 0.4% to about 33.6% TAR at 120 DAT in samples incubated at 10°C. After fractionation of the organic matter, the NER fraction was split up into humin, fulvic acid, and humic acid fraction accounting for 18.8, 5.2, and 6.0% TAR at 20°C, respectively, and 16.6, 5.6 and 5.7% TAR at 10°C, respectively. Results of the fractionation are presented in Table 7.1.2.1.1-4.

C. VOLATILIZATION

Besides the formation of NER, the formation of CO_2 was an important degradation pathway of alpha-cypermethrin. Hence, the fraction of $^{14}CO_2$ accounted for means of 51.4% and 31.8% TAR for soil samples incubated at 20°C and 10°C, respectively. Other radioactive residues recovered in the ethanediol traps were negligible (less than 1% TAR).

D. TRANSFORMATION OF PARENT COMPOUND

All combined soil extracts were analyzed by radio-HPLC. The results obtained with this system are summarized in Table 7.1.2.1.1-5 and Table 7.1.2.1.1-7.

HPLC analysis of the soil extracts indicated that alpha-cypermethrin was rapidly degraded at each temperature. Alpha-cypermethrin quantitatively accounted for the applied radioactivity at zero time and these levels subsequently decreased to a mean of 7.5% TAR at 20°C and 26.7% TAR at 10°C, respectively, after 120 days of incubation. In addition to parent material, low levels of CL 206128 (3-PBA) were detected in samples at 7 DAT in both groups accounting for less than 9% TAR. A minor unknown component, designated A, was detected in all samples after 3 DAT. At 20°C, levels of this component accounted for a maximum of 4.9% TAR in a single 7 DAT replicate and subsequently decreased to a mean value of 1.7% TAR at study termination. Unknown A accounted for a maximum of 8.1% TAR in a single 10°C replicate at 14 DAT and decreased to a mean value of 5.3% TAR at 120 DAT. Two further minor components, designated B and C, and polar material were detected at intervals throughout the incubation period in both groups each accounting for less than 5% TAR.

TLC analysis of soil extracts from 7 DAT and 120 DAT confirmed the results obtained by HPLC.

HPLC analysis of the fulvic acid fractions following fractionation of the organic matter indicated the presence of a polar component in samples from both groups. Two minor components, designated D and E, were also detected in the sample from Group B accounting for less than 1% TAR. Alpha-cypermethrin was not detected in any of the fulvic acid fractions.

Calculation of the degradation rates

Using simple first-order kinetics, the predicted concentrations after 40 days are below the measured values, even though the overall r^2 values were relatively high. Using biphasic first-order kinetics significantly improved the fit, as all time points could be well described. The r^2 values with biphasic kinetics were higher than with simple first-order kinetics, and the residuals were evenly distributed with time. Therefore, first-order DT_{50} values of 19.3 d at 20°C and 49.9 d at 10°C, and DT_{90} values of 104.0 d at 20°C and 233.0 d at 10°C, obtained from the biphasic fits were preferred (Table 7.1.2.1.1-9**:**).

Table 7.1.2.1.1-9: Estimated first-order DT_{50} and DT_{90} values of alpha-cypermethrin optimized with ModelMaker 4.0*

Temperature	Kinetic model	DT_{50} [d]	DT_{90} [d]	r^2
20°C	Simple first-order	20.6	68.3	0.987
	Biphasic first-order	19.3	104.0	0.997
10°C	Simple first-order	54.9	182.5	0.962
	Biphasic first-order	49.9	233.0	0.982

* calculated at the time of study conduction; an actual kinetic evaluation of the study data following FOCUS recommendations [FOCUS (2006) "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 1.0 (November 2011), 436 pp.] can be found in section CA 7.1.2.1.1/3.

III. CONCLUSION

Under the conditions of the study, alpha-cypermethrin degraded quickly in a sandy loam soil at two incubation temperatures. $^{14}CO_2$ was the principal degradation product detected and accounted for ca 51% and ca 32% TAR in soils incubated at 20°C and 10°C, respectively. Low levels of CL 206128 (3-PBA), three unknown components, and polar material were also extracted from the soil.

The DT_{50} and DT_{90} values for the degradation of alpha-cypermethrin in soil incubated at 20°C were estimated as 19 - 20 and 68 - 104 days, respectively. The corresponding values for soil incubated at 10°C were 50 - 55 and 183 - 233 days.

In conclusion, based on the results of this study and the estimated DT_{50} data, it is unlikely that alpha-cypermethrin will persist in soil.

Report:	CA 7.1.2.1.1/2 Singh M., 2003 a Isolation and identification of an unknow metabolite A of Alphacypermethrin (BAS 310 I) found in the Inveresk study 399307 (Degradation in soil under aerobic conditions) 2003/5000474
Guidelines:	EEC 91/414 Annex II 7.1.1.1.1
GLP:	yes (certified by United States Environmental Protection Agency)

Executive Summary

An aerobic degradation study was conducted by INVERESK RESEARCH using ^{14}C-alpha-cypermethrin for about 120 days [*CA 7.1.2.1.1/1, BASF DocID 2001/7001614 (AL-620-013)*]. The test soil was sandy loam and was supplied and characterized by Levington Agriculture (lpswich, UK). One of the metabolites, designated as unknown metabolite A, was a minor degradation product in both experiments (10°C and 20°C) and declined over time. The maximum amount of unknown A found in the 20°C experiment was 4.85% TAR at 7 DAT. The maximum amount of unknown A found in the 10°C experiment was 8.14% TAR, but was in excess of 5% TAR at several sampling intervals. Therefore, an attempt was made to isolate and identify the unknown metabolite A. Based on the chromatographic characteristics and the MS/MS data, the unknown metabolite A has been assigned the molecular formula $C_{22}H_{19}0_4NCl_2$ (Nominal Molecular Weight 432). The proposed chemical structure is shown in the discussion section.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Substance

No test substance was applied to the test soils in this study. Soil samples extracted and analyzed in this study for the identification of the unknown metabolite A were generated in the aerobic degradation study of alpha-cypermethrin [*CA 7.1.2.1.1/1, BASF DocID 2001/7001614 (AL-620-013)*].

2. Soil

The soil samples extracted in this study were generated in the aerobic degradation study of ^{14}C-alpha-cypermethrin [*CA 7.1.2.1.1/1; BASF DocID 2001/7001614 (AL-620-013)*]. Additionally, some of the unused extracts from this study were also utilized for the isolation of unknown metabolite A.

B. STUDY DESIGN

1. Description of analytical procedures

Extraction

The soil samples available for extraction, were split almost equally and transferred into four centrifuge tubes. The samples were then extracted with a mixture of acetonitrile and water (70/30, v/v; ~150 mL). Each extraction was performed by shaking the soil and the solvent mixture for about one hour at 300 rpm followed by centrifugation for 15 minutes. Three additional extractions were performed following this procedure. The supernatants from all four extractions were combined, measured and aliquots of the combined supernatant were assayed by liquid scintillation counting (LSC) to determine the amount total radioactivity available for the isolation of the unknown A and to track the material balance during further processing of the combined extract.

Isolation

The acetonitrile/water extract was concentrated on a rotary evaporator to remove most of the acetonitrile. Then, the aqueous solution was transferred to a separatory funnel and extracted with ethyl acetate (3x). The ethyl acetate extracts were combined and measured. Aliquots (3x) of the combined ethyl acetate extracts and aqueous layers were assayed by LSC to estimate the amount of radioactivity present in the ethyl acetate fraction and the aqueous fraction. Next, the ethyl acetate extract was concentrated on a rotary evaporator to almost dryness. The residual material was dissolved in acetonitrile. The acetonitrile solution was loaded on a pre-conditioned silica gel column and successively eluted with n-hexane, acetonitrile, and ethyl acetate. All eluants (n-hexane, acetonitrile, and ethyl acetate) were measured and assayed by LSC to determine the amount of the radioactivity in each eluant. Most of the radioactivity was found in the acetonitrile eluant.
The unprocessed acetonitrile/water extracts, received from INVERESK RESEARCH, were also processed in the same manner as described above.

The acetonitrile eluates obtained as mentioned above were washed with n-hexane to remove the majority of parent material (alpha-cypermethrin) present in the acetonitrile eluate. Next, the acetonitrile fraction was concentrated to approximately 5.0 mL.

ldentification of the isolated unknown metabolite A by mass spectrometry

An aliquot of the isolated ^{14}C-unknown A was analyzed by mass spectrometry (APCI, LC-MS/MS positive ion mode).

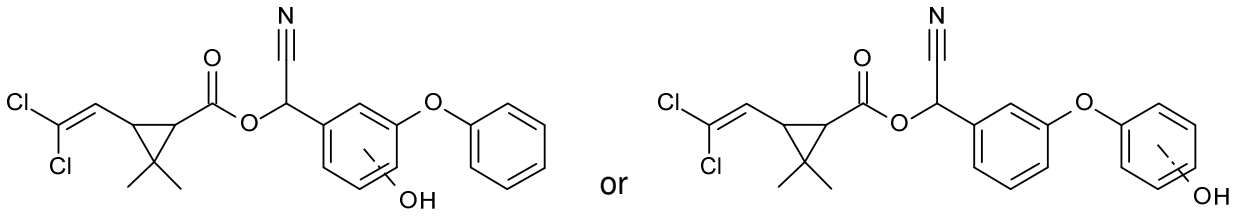
II. RESULTS AND DISCUSSION

A. STORAGE STABILITY

For the identification work, samples (both extracts and unextracted soil samples) generated in the aerobic degradation study [*CA 7.1.2.1.1/1; BASF DocID 2001/7001614 (AL-620-013)*] were used in this study. The soil extract was analyzed by HPLC after and before storage of about 2 years. The HPLC results show no change in the profiles. Therefore, the unknown metabolite A was stable during the storage period.

B. IDENTIFICATION OF THE UNKNOWN METABOLITE A

The identity of the degradation product unknown A found in the study was established by a combination of HPLC data and mass spectrometric analysis. The chromatographic data suggest that the unknown metabolite A has all the structural features of alpha-cypermethrin and no cleavage of either the ester bond or ether bond in alpha-cypermethrin has taken place. These conclusions are also supported by mass spectroscopy data.
The MS/MS data for the isolated unknown metabolite A is consistent for the following structures:



III. CONCLUSION

The metabolite unknown A, found in the aerobic degradation of alpha-cypermethrin, is a mono hydroxylation product of alpha-cypermethrin. Hydroxylation has taken place at one of the carbon atoms in the diphenoxy ether moiety of alpha-cypermethrin. The position could not be confirmed by MS. As in the recent metabolism studies, a metabolite with the hydroxylation in the para position of the phenyl ring was identified (M310I017), it seems likely that metabolite A has the same structure and is identical to M310I017.

Report:	CA 7.1.2.1.1/3 Sachers S., 2014 a Kinetic evaluation of aerobic soil degradation of BAS 310 I - alpha-cypermethrin: Determination of trigger and modeling endpoints according to FOCUS 2014/1159505
Guidelines:	FOCUS Kinetics (2006) SANCO/10058/2005 version 1.0 of Nov. 2011
GLP:	no

Executive Summary

The degradation behavior of the insecticide alpha-cypermethrin (BAS 310 I) in soil has been investigated in a laboratory study under aerobic degradation conditions with one soil at two different temperatures (10°C and 20°C). The purpose of this evaluation was to analyze the degradation kinetics of alpha-cypermethrin observed in the study according to current guidance of the FOCUS workgroup on degradation kinetics.

The appropriate kinetic models to derive trigger and modeling endpoints were identified considering the procedures and kinetic models proposed by the FOCUS kinetics guidance.

The best-fit model to derive trigger endpoints was selected based on a visual and statistical assessment. Normalization of $DegT_{50}$ values suitable for modeling to reference moisture was not necessary as the soil moisture at study conditions was higher than the reference moisture.

The kinetic evaluation showed that the DFOP model provided the best fit to the measured data for alpha-cypermethrin incubated at 10°C while the SFO model was appropriate for derivation of modeling endpoints. For the experiment conducted at 20°C the FOMC model provided the best fit and was also appropriate for derivation of modeling endpoints.

Best-fit $DegT_{50}$ as well as $DegT_{90}$ values, derived for the use as trigger endpoints, were calculated as 48.1 and 228.7 days at 10°C and 18.3 and 84.8 days at 20°C, respectively. Modeling $DegT_{50}$ values were calculated as 54.7 days at 10°C and 25.5 days at 20°C.

I. MATERIAL AND METHODS

The degradation of alpha-cypermethrin in one soil at two different temperatures [see *CA 7.1.2.1.1/1, BASF DocID 2001/7001614 (AL-620-013)*] was analyzed taking into account the current guidance of the FOCUS workgroup on degradation kinetics [*FOCUS (2006)*].

Kinetic modeling strategy

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. The best-fit model was selected based on visual and statistical assessment and the corresponding $DegT_{50}$ and $DegT_{90}$ values are reported as trigger endpoints. Appropriate $DegT_{50}$ values for use in environmental fate models were derived depending on the kinetic model.

Kinetic models included in the evaluations

For each data set, the kinetic models proposed by FOCUS Kinetics [*FOCUS (2006)*] were tested in order to identify the best-fit model, i.e. single first order (SFO) kinetics, the Gustafson-Holden model (FOMC), and the bi-exponential (DFOP) kinetics. The respective model descriptions and corresponding equations for calculating endpoints ($DegT_{50}$, $DegT_{90}$) are shown in the FOCUS Kinetics guidance [*FOCUS (2006)*].

A kinetic model is considered appropriate if the residuals are randomly distributed around zero, the χ^2 error indicates a sufficient quality of the fit (e.g. value is ideally < 15% but may be higher if the visual fit represents the degradation behavior well), and the estimated degradation parameters differ significantly from zero.

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures, as recommended by the FOCUS Kinetics guidance [*FOCUS (2006)*].

Data handling and software for kinetic evaluation

The experimental data were derived from the study report [*CA 7.1.2.1.1/1, BASF DocID 2001/7001614 (AL-620-013)*] and the initial concentration of alpha-cypermethrin was set to the material balance. For all samplings, duplicate measurements were considered for the parameter estimation.

The software package KinGUI version 2.2014.224.1704 was used for parameter fitting. The error tolerance and the number of iterations of the optimization tool (IRLS) were set to $1x10^{-6}$ and 100, respectively.

Normalization to reference conditions

According to FOCUS, $DegT_{50}$ values suitable for modeling should be normalized to reference moisture at field capacity (pF 2) if the experiment was conducted at a lower soil moisture.

In the evaluated study the actual soil moisture of 21.1 g per 100 g dry soil (i.e. 50% of the maximum water holding capacity (MWHC) of 42.2 g per 100 g dry soil) is higher than the reference soil moisture of 19 g per 100 g dry soil (moisture at pF 2 of a sandy loam of according to FOCUS. Hence, further normalization of the calculated $DegT_{50}$ suitable for modeling was not necessary.

Experimental data

The kinetic evaluation was conducted for one aerobic laboratory soil degradation study [see *CA 7.1.2.1.1/1, BASF DocID 2001/7001614 (AL-620-013)*]. Detailed soil characteristics in each trial are reported in the cited study.

The test soil treated with benzyl ring-U-^{14}C labeled alpha-cypermethrin at a nominal application rate of 0.3 mg kg^{-1} dry soil, corresponding to 300 g a.s. ha^{-1} (i.e. tenfold of the maximum recommended field application rate), was incubated under dark aerobic conditions at two temperatures (20ºC and 10°C, respectively) and 50% MWHC for 120 days. Soil samples were taken at 0, 3, 7, 14, 28, 42, 70 and 120 days after treatment (DAT).

The measured data as well as resulting datasets submitted to kinetic analysis are given in Table 7.1.2.1.1-10**:** .

II. RESULTS AND DISCUSSION

The kinetic evaluation showed that the DFOP model provided the best fit to the measured data for alpha-cypermethrin incubated at 10°C while the SFO model was appropriate for derivation of modeling endpoints. For the experiment conducted at 20°C, the FOMC model provided the best fit and was also appropriate for derivation of modeling endpoints.

A summary of the calculated trigger and modeling endpoints for alpha-cypermethrin is given in Table 7.1.2.1.1-11 and Table 7.1.2.1.1-12.

Table 7.1.2.1.1-11: Trigger endpoints for alpha-cypermethrin

Study	Incubation temperature [°C]	Best-fit model	$\chi 2$ error	p (t-test)	Visual fit	$DegT_{50}$ [d]	$DegT_{90}$ [d]

III. CONCLUSION

Trigger and modeling endpoints were derived for alpha-cypermethrin in a laboratory degradation study at two different temperatures.

The kinetic evaluation revealed that the DFOP model provided the best fit to the measured data for alpha-cypermethrin incubated at 10°C while the SFO model was appropriate for derivation of modeling endpoints. For the experiment conducted at 20°C, the FOMC model provided the best fit and was also appropriate for derivation of modeling endpoints.

Best-fit $DegT_{50}$ as well as $DegT_{90}$ values, derived for the use as trigger endpoints, were calculated as 48.1 and 228.7 days at 10°C and 18.3 and 84.8 days at 20°C, respectively. Modeling $DegT_{50}$ values were calculated as 54.7 days at 10°C and 25.5 days at 20°C.

Report:	CA 7.1.2.1.1/4 Michel, A., Hassink, J., 2014 b Rate of degradation of alpha-cypermethrin (BAS 310 I) in soil under aerobic conditions 2014/1159491
Guidelines:	OECD 307, EPA 835.4100, SETAC Procedures for assessing the environmental fate and ecotoxicity for pesticides (March 1995)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The degradation rate of alpha-cypermethrin (BAS 310 I) was investigated under aerobic conditions in three German soils (Li10, LUFA 2.2, and LUFA 2.3).

The soils were treated with cyclopropane-1-^{14}C-labeled-alpha-cypermethrin and benzyl-^{14}C-labeled-alpha-cypermethrin at a nominal rate of 0.3 mg kg^{-1} dry soil. Soil aliquots were incubated in the laboratory in the dark under aerobic conditions with soil moistures between 40% and 50% of the maximum water holding capacity (MWHC) and a temperature of 20°C ± 2°C. An incubation system with continuous aeration was used with an attached trapping system for the determination of volatile compounds. The microbial biomass was determined by the substrate induced respiration method before the start of the study, after 71 and 136 days of incubation.

Samples were taken 0, 1, 3, 7, 10, 14, 60, 87 and 120 days after treatment (DAT). All soil samples were worked up in duplicate. The soil samples were extracted four times with ACN/H_2O/HCOOH (700/300/1, v/v/v) and the individual extracts analyzed by liquid scintillation counting (LSC). The combined extracts were then concentrated and analyzed by LSC and high performance liquid chromatography (HPLC). The remaining soil after extraction was combusted in order to determine the amount of non-extractable soil bound residues. Additionally, the amount of formed volatiles was determined for each sampling point except on day 0. A full mass balance was provided for each sampling interval.

The amount of extractable radioactivity continuously decreased in the aerated soils to 27.9%, 39.9%, and 16.6% TAR after 120 days of incubation for the soils Li10, LUFA 2.2, and LUFA 2.3, respectively. The amount of non-extractable radioactive residues (NER) increased during the study from 0.6%, 1.5%, and 1.3% TAR at day 0 to 32.2%, 23.5%, and 34.8% TAR after 120 days of incubation for the soils Li10, LUFA 2.2, and LUFA 2.3, respectively. Mineralization reached a total of up to 48.8% TAR after 120 days. The mass balance ranged from 88.3% to 111.0% TAR.

The NER fraction was further characterized exemplarily for one replicate at 60 DAT and 120 DAT. After 120 days, 7.0%, 3.8%, and 7.8%, TAR remained unextractable for the soil Li10, LUFA 2.2, and LUFA 2.3 respectively. This portion of unextractable radioactivity was assigned to the humin fraction. The alkali-soluble radioactivity was further fractionated by precipitation with concentrated HCl. After 120 days, 10.8% TAR (Li10), 10.5%TAR (LUFA 2.2), and 14.9% TAR (LUFA 2.3) could be assigned to the fulvic acids fraction and 14.1% TAR (Li10), 7.9%TAR (LUFA 2.2), and 6.8% TAR (LUFA 2.3) to the humic acids fraction.

The humic acid fraction was not further analyzed. The fulvic acid fraction was partitioned with ethyl acetate for two exemplary samples (60 and 120 days). At 120 DAT, about 6.9% and 3.3% TAR (Li10), 5.3% and 4.3% TAR (LUFA 2.2), and 8.1% and 6.7% TAR (LUFA 2.3) of the fulvic acid fraction were soluble in the water phase and the ethyl acetate phase, respectively.

The parent compound decreased continuously from 99.4%, 98.5%, and 98.7% TAR at day 0, to 20.8%, 30.1%, and 10.5% TAR at the end of the incubation for the soils Li10, LUFA 2.2, and LUFA 2.3 respectively.

One metabolite was observed in the soil extracts, at maximum amounts of 5.8, 5.9, and 5.3% TAR in soils Li10, LUFA 2.2 and LUFA 2.3, respectively. The maxima were reached between 10 and 30 days after application, with a decrease thereafter. This metabolite was identified by mass spectrometry (MS) and nuclear magnetic resonance (NMR) measurements as M310I017.

Kinetic evaluation was performed following the recommendations of the FOCUS Kinetics workgroup in order to derive trigger and modeling endpoints. The following $DegT_{50}$ and $DegT_{90}$ values were calculated (Table 7.1.2.1.1-13 to Table 7.1.2.1.1-16):

Table 7.1.2.1.1-13: Trigger endpoints for alpha-cypermethrin

Soil	Compound	Best-fit model	χ^2 error	$DegT_{50}$ [d]	$DegT_{90}$ [d]

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS-Code: BAS 310 I (alpha-cypermethrin)
Chemical name: Racemate of (S)-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Molecular formula: $C_{22}H_{19}Cl_2NO_3$
Molar mass: 416.3 g mol^{-1} (unlabeled)

Label 1 (cyclopropane label)
Label: cyclopropane-1-^{14}C
Batch No.: 986-2101
Specific activity of a.s.: 4.71 MBq mg^{-1}
Radiochemical purity: 96.9%
Chemical purity: 91.8%

Label 2 (benzyl label)
Label: benzyl-1-^{14}C
Batch No.: 775-0601
Specific activity of a.s.: 4.74 MBq mg^{-1}
Radiochemical purity: 99.5%
Chemical purity: 96.1%

2. Soils

Three German agricultural soils (Li10, LUFA 2.2, and LUFA 2.3) were used for treatment and incubation. The soils were sieved through a 2 mm sieve before use and stored at about 4°C in the dark no longer than 3 months before use. The soil characteristics are summarized in Table 7.1.2.1.1-17.

Table 7.1.2.1.1-17: Properties of soils used for investigation of alpha-cypermethrin degradation rates under aerobic conditions

Soil designation	**Li10 Limburgerhof 13/1680/04** (Germany)	**LUFA 2.2 Mechtersheim 13/736/04** (Germany)	**LUFA 2.3 Hanhofen 13/570/04** (Germany)

Microbial biomass (day 136) [mg C $100g^{-1}$ dry soil]	7.1	13.1	12.4

B. STUDY DESIGN

1. Experimental conditions

The soils were adjusted to about 40% (Li10), 45% (LUFA 2.2), and 50% (LUFA 2.3) of the maximum water holding capacity (MWHC) and treated at a nominal application rate of 0.08 mg alpha-cypermethrin per kg dry soil which corresponds to a field application rate of 30 g a.s. ha^{-1} (calculated on the basis of an equal distribution in the top 2.5 cm soil layer and a soil density of 1.5 g cm^{-3}). Because of the low specific radioactivity of the test items and to ensure a better detection of possible degradation products, the amount of test item applied was increased to 0.3 mg test item kg^{-1} dry soil.

After application to bulk soil, portions of 100 g soil (dry weight basis) treated with either benzyl-^{14}C-labeled test item (Li10) or cyclopropane-^{14}C-labeled test item (LUFA 2.2 and LUFA 2.3) were filled into test vessels. The number of vessels was sufficient to allow duplicate sampling at each sampling time and to keep a limited number of reserve vessels.

The vessels were incubated in the dark for 120 days at a temperature of 20°C ± 2°C. Throughout the incubation period, the test vessels were continuously aerated with a slight stream of moistened synthetic air. The outgoing air was led through a series of gas-washing bottles containing trapping solutions for potential volatiles (ethylene glycol, 0.5 M H_2SO_4, 0.5 M NaOH). The water content of the soils was monitored throughout the incubation period by weighing the sampled vessels and evaporated water was replaced.

2. Sampling

Sampling times for the three soil types Li10, LUFA 2.2 and LUFA 2.3 were 0, 1, 3, 7, 10, 14, 30, and 60, 87, and 120 days after treatment (DAT).

At each sampling time, two replicate vessels with soil were removed from the incubation cabinet. Besides day 0, the volatile trapping solutions were sampled and replaced by new flasks with fresh solutions. The sampled trapping solutions were measured for radioactivity by liquid scintillation counting (LSC).

3. Description of the analytical procedures

The soils were consecutively extracted four times with 120 mL acetonitrile/water/formic acid (700/300/1, v/v/v) by shaking for about one hour. After each extraction, the suspension was centrifuged, filtered, and aliquots of each solution were radioassayed.

The four acetonitrile/water/formic acid extracts were combined and concentrated to dryness, re-dissolved in the extraction solvent and analyzed by LSC. Aliquots of the combined extracts were analyzed by LSC. After an additional concentration step, HPLC was performed to obtain the metabolite pattern. Separation of cis and trans isomers, as well as enantiomers of alpha-cypermethrin was performed on two separate HPLC systems.

In order to identify the peak of the unknown metabolite at about 74 min, fraction collection was performed with replicate 2 of the 10 DAT sample. Additionally, also the parent peak was isolated. After two steps of concentration to dryness and redissolving, both fractions were measured by LSC, radio-HPLC, and HPLC-MS.

Furthermore, samples of rat feces from a rat metabolism study [*CA 5.1.1/2, BASF DocID 2013/1086630*] were extracted twice with 150 mL acetonitrile by shaking for 30 min. After centrifugation and combination of the two extracts, aliquots were analyzed by LSC. Aliquots were concentrated to dryness, redissolved in ACN/H_2O/HCOOH (7/3/1, v/v/v) and analyzed by LSC. Fraction collections were performed as described in detail in the study report. The fractions were combined, concentrated, and analyzed by LSC, HPLC, MS and NMR.

The extracted soil was dried under the fume hood at room temperature and afterwards grounded in an analytical mill. Aliquots were combusted in order to determine the amount of non-extractable radioactive residues. The evolved $^{14}CO_2$ from each combusted aliquot was trapped in an Oxysolve C-400 scintillator and measured by LSC.

The fraction of NER was further characterized by NaOH extractions (0.5 M NaOH, three times). NaOH extracts were processed to determine the distribution of radioactivity to the humin, humic, and fulvic acid fractions. The humic acid fraction and the fulvic acid fraction were analyzed by LSC. The fulvic acid fraction was further partitioned with ethyl acetate. Concentrated ethyl acetate phases were analyzed by HPLC. The remaining radioactivity in the soil residues was determined by combustion analyses (humin fraction). Further details are given in the report.

The microbial biomass in the soil samples treated with and without solvent was determined before the start of the study, at 61 and 137 DAT. The method was based on the determination of oxygen consumption upon addition of glucose. In all three soils, the microbial biomass declined over the incubation phase. However, the results demonstrate that the soils were still viable and microbially active after 71 and 136 days.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints). Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values was performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006) "Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration" Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 2.0, 434 pp.*].

The software package KinGUII (version 2.2014.224.1704) was used for parameter fitting [*SCHÄFER, D., MIKOLASCH, M., RAINBIRD, P., HARVEY, B. (2007*, *WITT, J., GAO, Z., MEYER, H. (2014)*]. The error tolerance and the number of iterations of the optimization tool were set to 0.00001 and 100, respectively.

For each data set, the kinetic models proposed by the FOCUS Kinetics guidance document were tested in order to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO), the Gustafson-Holden model (FOMC), and bi-exponential (DFOP) kinetics are already implemented in KinGUI. The Goodness-of-fit was evaluated by visual assessment, χ^2 minimum error, and type-I-error rate (t-test) [for details see Chapter 6.3 in *FOCUS (2006)*].

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The detailed results on the radioactive residues in the soils are presented in Table 7.1.2.1.1-18 to Table 7.1.2.1.1-20. The material balance throughout the incubation period ranged from 98.8 to 111.0% TAR for soil Li10, from 100.0 to 104.8% TAR for soil LUFA 2.2 and from 88.3 to 103.9% TAR for soil LUFA 2.3.

B. EXTRACTABLE AND BOUND RESIDUES

The distribution of radioactivity in extractable residues (ERR), non-extractable residues, CO_2 and other volatiles for each soil is shown in Table 7.1.2.1.1-18 to Table 7.1.2.1.1-20.

The amount of extractable radioactivity decreased steadily in the aerated soils to 27.9%, 39.9%, and 16.6% TAR at the end of the incubation for the soils Li10, LUFA 2.2, and LUFA 2.3, respectively.

The non-extractable radioactive residues (NER) increased during the study from 0.6%, 1.5%, and 1.3% TAR on day 0 to 32.2%, 23.5%, and 34.8% TAR after 120 days of incubation for the soils Li10, LUFA 2.2, and LUFA 2.3, respectively.

* No other volatiles than CO_2 were found

C. VOLATILIZATION

Mineralization reached a total of up to 48.8% TAR after 120 days of incubation (in soil Li10). No other volatiles than $^{14}CO_2$ occurred.

D. TRANSFORMATION OF PARENT COMPOUND

All combined soil extracts were analyzed by radio-HPLC. The results are summarized in Table 7.1.2.1.1-21 to Table 7.1.2.1.1-23.

Considering all three soils, the concentration of alpha-cypermethrin decreased throughout the incubation period from 99.4%, 98.5%, and 98.7% TAR at day 0, to 20.8%, 30.1%, and 10.5% TAR at the end of the incubation for the soils Li10, LUFA 2.2, and LUFA 2.3, respectively.

Several degradation products were detected in the extracts but only one peak appeared in amounts higher than 5% TAR. The unknown metabolite eluting after 74 min was present in the soil extracts in amounts of max. 5.8%, 5.9%, and 5.3% TAR in soils Li10, LUFA 2.2, and LUFA 2.3, respectively. The maxima were reached between 10 and 30 days after application with a decrease thereafter.

The unknown peak at around 74 min was isolated via HPLC fraction collection and MS analysis was performed. MS analysis identified the unknown substance as the product of the hydroxylation of alpha-cypermethrin on the benzyl ring. However, it did not provide information on the exact position of the hydroxylation (ortho, meta, or para position).

Since a hydroxylated metabolite was identified in the rat metabolism study [*CA 5.1.1/2, BASF DocID 2013/1086630*], the corresponding rat sample was newly extracted and the hydroxylated metabolite was isolated by fraction collection. The collection was analyzed by HPLC-MS and NMR, and it could be confirmed that the hydroxylation is located on the para position of the benzyl ring (M310I017). The identification of M310I017 in the soil extracts was confirmed for each soil by co-chromatography with an exemplary soil extract (10 DAT, replicate 1).

TAR = Total applied radioactivity
* individual peaks < 3% TAR

Throughout the study, only one peak was observed in the chromatograms containing only cis isomers. This confirmed that no trans isomers were formed during the study.

Separation of enantiomers was performed by chiral HPLC. A change of the enantiomeric ratio from 1.0 to 1.5, 2.3, and 2.0 could be observed in the soils Li10, LUFA 2.2, and LUFA 2.3, respectively. The results of the determination of the R/S ratio of the CN-bearing carbon atom of alpha-cypermethrin are presented in Table 7.1.2.1-24, as well as in the study report.

E. CHARACTERIZATION OF NON-EXTRACTABLE ("BOUND") RESIDUES

Summaries of bound residue fractionating following extraction by NaOH and H_2O are given in Table 7.1.2.1.1-25 to Table 7.1.2.1.1-27.

After 120 days of incubation, 10.8% TAR could be assigned to the fulvic acids fraction and 14.1% TAR to the humic acids fraction in soil Li10. On soil LUFA 2.2, 10.5% TAR could be assigned to the fulvic acids fraction and 7.9% TAR to the humic acids fraction. On soil LUFA 2.3, 14.9% TAR could be assigned to the fulvic acids fraction and 6.8% TAR to the humic acids fraction at 120 DAT.

About 5.5%, 3.2%, and 7.8% TAR remained unextractable for the soils Li10, LUFA 2.2, and LUFA 2.3 after 60 days. After 120 days, 7.0%, 3.8%, and 7.8% TAR remained unextractable for the soil Li10, LUFA 2.2, and LUFA 2.3, respectively. This portion of unextractable radioactivity was assigned to the humin fraction.

The ethyl acetate phase was further analyzed by HPLC. The main peak was found to occur with a maximum of 5.5% TAR at 60 DAT for the cyclopropane-1-^{14}C-labeled-alpha-cypermethrin on soil LUFA 2.3. No further attends were made to identify the compounds observed in the water phase.

Table 7.1.2.1.1-25: Characterization of bound residues [% TAR]

Soil	DAT	NER*	ERR II			NER II (Humins)	Sum ERR II + NER II*
			NaOH	H_2O	Total		
Li10	60 [rep 2]	29.9	21.0	0.8	21.8	5.5	27.3
Li10	120 [rep 2]	32.1	24.3	1.0	25.3	7.0	32.3

III. CONCLUSION

Alpha-cypermethrin degraded in aerobic soils with DT_{50} values of 28.3, 35.0 and 24.3 days in the soils Li10, LUFA 2.2, and LUFA 2.3, respectively. At the same time the fraction of non-extractable residues increased reaching between 23.5 and 34.8% TAR at the end of the study after 120 days. $^{14}CO_2$ was formed in significant amounts (between 36.9% and 48.8% TAR).

The metabolite M310I017 was observed with maximum concentrations in the range 5.3% - 5.9% TAR. The metabolite M310I017 was observed in the extracts of all three soils. Some enantioselectivity was observed in the degradation with fater degradation of the R enantiomer.

Normalization of laboratory degradation endpoints to reference conditions

Since for environmental fate modeling soil $DegT_{50}$ values at reference conditions (temperature of 20°C and soil moisture at field capacity, i.e. pF2) are required, the modeling endpoints ($DegT_{50}$) reported in CA 7.1.1.1/1 [*BASF Doc ID 2014/1000641*], CA 7.1.2.1.1/4 [*BASF Doc ID 2014/1159491*], and CA 7.1.2.1.2 [*CLASS T. and DORN U. (2003)*] were normalized following the recommendations of FOCUS [*FOCUS (2012): Generic Guidance for Tier 1 FOCUS Ground Water Assessments, version 2.1 (Dec. 2012), 64 pp.*]. Since the laboratory studies were performed at 20°C, a temperature correction was not necessary. The soil moisture normalization was performed using the moisture dependency equations by Walker as described in Equation 7.1.2.1.1-1.

Equation 7.1.2.1.1-1: Calculation of the moisture correction factor according to Walker

$$f_{moist} = \begin{cases} \left(\frac{\theta_{act}}{\theta_{ref}}\right)^{0.7} & if \quad \theta_{act} < \theta_{ref} \\ 1 & if \quad \theta_{act} \geq \theta_{ref} \end{cases}$$

with:	f_{moist}	moisture correction factor	[-]
	θ_{ref}	reference soil moisture at field capacity (pF2, 10 kPa)	[g / 100 g dry soil]
	θ_{act}	actual soil moisture during incubation	[g / 100 g dry soil]

For [*BASF Doc ID 2014/1000641*] and [*BASF Doc ID 2014/1159491*], the actual soil moisture and the reference moisture were taken from the study reports. For Class and Dorn [*CLASS T. and DORN U. (2003)*], the actual soil moisture was taken from the study report and the reference soil moisture was derived from FOCUS [*FOCUS (2012)*]. The normalized $DegT_{50}$ values were calculated by multiplying the $DegT_{50}$ values at study conditions by the correction factor f_{moist} as described in Equation 7.1.2.1.1-2.

Equation 7.1.2.1.1-2: Calculation of the $DegT_{50}$ at reference conditions (20°C, pF2)

$$DegT_{50,ref} = DegT_{50,act} \times f_{moist}$$

with:	$DegT_{50,ref}$	normalized $DegT_{50}$	[d]
	$DegT_{50,act}$	$DegT_{50}$ at study conditions	[d]
	f_{moist}	moisture correction factor	[-]

Parameters included in the normalization procedure and the resulting normalized $DegT_{50}$ values for modeling are summarized in Table 7.1.2.1.1-32.

Table 7.1.2.1.1-32: Normalization of alpha-cypermethrin $DegT_{50}$ values to reference conditions

Study	Soil	Kinetic model	θ_{act}	θ_{ref}	f_{moist}	$DegT_{50,act}$ [d]	$DegT_{50,ref}$ [d]

CA 7.1.2.1.2 Aerobic degradation of metabolites, breakdown and reaction products

Report: CA 7.1.2.1.2/1
Sacchi R.R., 2015 a
Rate of Degradation of 3-Phenoxybenzoic Acid (Reg. No. 130213) (metabolite of BAS 310 I) on European Soils at 20 ± 2ºC under aerobic conditions
2015/3003981

Guidelines: INMETRO NIT DICLA- 035 Rev. 02 (Sep. 2011), OECD 307 (2002), POP-PA.1006, EPA 835.4100

GLP: yes
(certified by Instituto Nacional de Metrologia, Normalizacao e Qualidade Industrial - INMETRO, Rio de Janeiro, Brazil)

Executive Summary

The objective of this study was to examine the aerobic degradation of 3-PBA (3-phenoxybenzoic acid, metabolite of alpha-cypermethrin, BAS 310 I) in three soils.

According to the USDA scheme, the soils were characterized as sandy loam (LUFA 5M), and loamy fine sand (LUFA 2.2, Li 10). Prior to application, the soil samples were acclimatized for 15 days and adjusted to 40% of their maximum water holding capacities.

The application rate (based on dry soil weight) of 3-PBA was 0.16 mg kg^{-1}. Assuming a soil depth of 2.5 cm and a soil density of 1.5 g cm^{-3} this corresponds to a theoretical field application rate of about 60 g ha^{-1}. The soil was filled into incubation flasks which were then placed in thermostated cabinet set to 20°C in the dark. Loss of soil water was controlled by weighing and re-adjusted with distilled water if necessary. The dosed soil samples were incubated for various intervals up to 14 days prior to extraction.

The analytical method was validated and revealed a limit of quantification (LOQ) of 0.001 mg kg^{-1} (0.6% of the initially applied residue (AR)) and a limit of detection (LOD) of 0.0003 mg kg^{-1} (0.1% AR) for 3-PBA.

Procedural recoveries were analysed together with treated samples.The mean recovery values were found to be within the acceptable ranged from 70 % to 120 % for all soils tested.

The residues observed for the analyte (expressed as mg kg^{-1}) in the incubated soil samples were fitted by using the software package KinGUI. The kinetic models employed for this evaluation were described by FOCUS Kinetics workgroup. The trigger endpoints for 3-PBA in the three soils examined were in the range of 0.3 to 1.7 days ($DegT_{50}$) and 2.6 to 5.5 days ($DegT_{90}$). The modeling endpoints for ETU were in the range of 0.8 to 1.7 days ($DegT_{50}$).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test compound: 3-PBA (Reg No.130213)
Chemical name (IUPAC): 3-Phenoxybenzoicacid
Batch No.: AC12251-34
Molar mass: 214.2 g mol^{-1}
Molecular formula: $C_{13}H_{10}O_3$
Purity: 100%

2. Soil

Three field-fresh soils were used in the study. The soils were kept under aerobic conditions and the evaporated water was added if necessary. The soil characteristics are summarized in Table 7.1.2.1.2-1.

Table 7.1.2.1.2-1: Characteristics of three soils

B. STUDY DESIGN

1. Experimental conditions

Soil samples were adjusted to 40% of their maximum water holding capacities and incubated at room temperature in the dark for 15 days prior to application.

The application rate (based on dry soil weight) of the analyte dosed to soil was 0.16 mg kg^{-1}. Assuming a soil depth of 2.5 cm and a density of 1.5 g cm^{-3} this rate correspond to a theoretical field application rate of about 60 g ha^{-1}. This rate was chosen under consideration of a reasonable good detectability in the present study.
One kg of each soil (dry soil) was treated with 1.0 mL of the treatment solution containing 0.160 mg 3-PBA). Samples were homogenized, and 50 g (dry weight based) were filled into test vessels. These were sealed with special caps with air inlet and outlet tubes. The samples were incubated in the dark at a temperature of (20 ± 2)°C and were aerated with a slight stream of moistened and CO2 free air. Loss of soil water was controlled by weighing and was re-adjusted with distilled water if necessary.

The treated soil samples were incubated for various intervals up to 14 days prior to extraction. Additionally, untreated moist bulks of soil were kept in the thermostated cabinet.

2. Sampling

Soil samples were removed from the thermostated cabinet for subsequent extraction after 0, 1, 3, 7, 9, and 14 days of incubation. Six samples were taken at time zero to prove the homogeneous distribution of the test substance in the soils. Duplicate samples were taken at all other sampling times.

3. Description of analytical procedures

BASF Analytical Method R0034/01 (BASF DocID 2015/7000103) was used for analysis. 5 g aliquots of the samples were extracted consecutively twice with 25 mL acetonitrile/water (70:30, v/v) on a laboratory shaker at 400 rpm for about 30 minutes. After each extraction step, the sample was centrifuged for 5 minutes at 4000 rpm and the supernatant was decanted into a 50 mL disposable centrifuge tube. An aliquot (10%) from the combined extract was evaporated to dryness using nitrogen at about 50ºC and then dissolved in methanol/water (20:80, v/v) with 0.1% formic acid. The concentrated extracts were sonicated for about 1-2 minutes and vortexed for about 15 seconds to ensure that all residues was dissolved. Prior to LC-MS/MS analysis, concentrated extracts were transferred into a HPLC vial using a syringe filter

The analytical method achieves a limit of quantification (LOQ) of 0.001 mg kg^{-1} and a limit of detection (LOD) of 0.0003 mg kg^{-1} for 3-PBA.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values was performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006)*].

The software package KinGUI (version 2.2012.320.1629) was used for parameter fitting [*SCHÄFER et al. (2007)*].

Modeling strategy

The kinetic models employed for this evaluation were described by FOCUS [*FOCUS (2006)*].

Trigger endpoints were derived from the kinetic model that provides the best fit to the measured data, generally indicated by the lowest χ^2 - error. Modeling endpoints were derived preferably from the SFO model. If the SFO model is not appropriate, pragmatic procedures were used to derive conservative pseudo-SFO degradation rates from the FOMC model by dividing $DegT_{90}$ by 3.32.

The appropriateness of the distinct kinetic model to describe soil degradation was tested by visual assessment. Furthermore, a kinetic model was considered appropriate for deriving trigger or modeling endpoints of χ^2 – error value was low (ideally below 15%).

Experimental data used for kinetic analysis

The experimental data were derived from the study reports and adjusted according to FOCUS [*FOUCS (2006)*].

The datasets submitted to kinetic analyses are given in Table 7.1.2.1.2-2.

II. RESULTS AND DISCUSSION

The three soils were incubated at (20 ± 2)°C and soil moisture of approximately 40 % of the maximum water holding capacity. A nominal application rate of 0.160 mg a.i./kg dry soil was used. The extractable residues at day 0 and ranged from 0.104 to 0.154 mg/kg dry soil. This corresponds to mean recovery values at day 0 of 94.2 %, 64.0 % and 73.8 % for Li10, LUFA 2.2 and LUFA 5M, respectively. The low recovery obtained for two soils is deemed to be caused by the very fast degradation of the compound, which already started during the sample preparation and application process. The degradation in each soil was followed for 14 days.
Procedural recoveries were determined for each soil and sampling date from day 1 onwards in triplicate. Overall mean recoveries were 93% (Li10), 97% (LUFA 2.2) and 99% (LUFA 5M). A potential matrix effect was investigated and was found to be below 20% in all cases.

Residues of the test item extracted from soil after given incubation periods are summarized in Table 7.1.2.1.2-3.

The calculated degradation parameters and kinetic endpoints of 3-PBA for use as triggers for additional work and for modeling are summarized in the following tables (Table 7.1.2.1.2-4 and Table 7.1.2.1.2-5).

For the evaluated soil degradation experiments, the visual assessment and the goodness-of-fit statistics show plausible fits. Therefore, the resulting $DegT_{50}$ / DT_{50} values can be considered reliable.

III. CONCLUSION

The objective of the study was to examine aerobic degradation of 3-PBA (metabolite of alpha-cypermethrin) in three soils. The trigger endpoints for 3-PBA in the six soils examined were in the range of 0.3 to 1.7 days ($DegT_{50}$) and 2.6 to 5.5 days ($DegT_{90}$). The modeling endpoints for 3-PBA were in the range of 0.8 to 1.7 days ($DegT_{50}$).
It could be demonstrated that 3-PBA is rapidly degraded in soil.

Executive Summary

The objective of this study was to examine the aerobic degradation of cis-DCVA (cis-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylic acid, metabolite of alpha-cypermethrin, BAS 310 I) in three soils.

According to the USDA scheme, the soils were characterized as sandy loam (LUFA 5M), and loamy fine sand (LUFA 2.2, Li 10). Prior to application, the soil samples were acclimatized for 15 days and adjusted to 40% of their maximum water holding capacities.

The nominal application rate (based on dry soil weight) of cis-DCVA was 0.160 mg kg^{-1}. Assuming a soil depth of 2.5 cm and a soil density of 1.5 g cm^{-3} this corresponds to a theoretical field application rate of about 60 g ha^{-1}. The soil was filled into incubation flasks, which were does individually and were then placed in thermostated cabinet set to 20°C in the dark. Loss of soil water was controlled by weighing and re-adjusted with distilled water if necessary. The dosed soil samples were incubated for various intervals up to 31 or 41 days prior to extraction.

The analytical method was validated and revealed a limit of quantification (LOQ) of 0.001 mg kg^{-1} (0.6% of the initially applied residue (AR)) and a limit of detection (LOD) of 0.0003 mg kg^{-1} (0.1% AR) for cis-DCVA.

Procedural recoveries were analysed together with treated samples.The mean recovery values were found to be within the acceptable ranged from 70 % to 110 % for all soils tested.

The residues observed for the analyte (expressed as mg kg^{-1}) in the incubated soil samples were fitted by using the software package KinGUI. The kinetic models employed for this evaluation were described by FOCUS Kinetics workgroup. The trigger and modeling endpoints for cis-DCVA in the three soils examined were in the range of 4.7 to 13.5 days ($DegT_{50}$) and 15.7 to 45.0 days ($DegT_{90}$).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test compound:	cis-DCVA (Reg No. 4080830)
Chemical name (IUPAC):	cis-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane-carboxylic acid
Batch No.:	AC12717-65
Molar mass:	209.01 g mol^{-1}
Molecular formula:	$C_8H_{10}Cl_2O_2$
Purity:	99.5%

2. Soil

Three field-fresh soils were used in the study. The soils were kept under aerobic conditions and the evaporated water was added if necessary. The soil characteristics are summarized in Table 7.1.2.1.2-6.

Table 7.1.2.1.2-6: Characteristics of three soils

B. STUDY DESIGN

1. Experimental conditions

Soil samples were adjusted to 40% of their maximum water holding capacities and incubated at room temperature in the dark prior to application.

The application rate (based on dry soil weight) of the analyte dosed to soil was 0.16 mg kg^{-1}. Assuming a soil depth of 2.5 cm and a density of 1.5 g cm^{-3} this rate correspond to a theoretical field application rate of about 60 g ha^{-1}. This rate was chosen under consideration of a reasonable good detectability in the present study.
50 g (dry weight based) of soil were filled into test vessels. The soil in each vessel was treated with 50 µL of a solution containing 0.160 µg/mL cis-DCVA. The soil in the vessels was mixed to achieve a homogenous distribution of the test compound in the soil. Then these vessels were sealed with special caps with air inlet and outlet tubes. The samples were incubated in the dark at a temperature of (20 ± 2)°C and were aerated with a slight stream of moistened and CO_2 free air. Loss of soil water was controlled by weighing and was re-adjusted with distilled water if necessary.

The treated soil samples were incubated for various intervals up to 41 days prior to extraction. Additionally, untreated moist bulks of soil were kept in the thermostated cabinet.

2. Sampling

Soil samples were removed from the thermostated cabinet for subsequent extraction after 0, 1, 3, 7, 10, 21, 31 and 41 days (LUFA 2.2 only 31 days) of incubation. Three samples were taken at time zero to prove the homogeneous distribution of the test substance in the soils. Duplicate samples were taken at all other sampling times.

3. Description of analytical procedures

BASF Analytical Method R0034/01 (BASF DocID 2015/7000103) was used for analysis. 5 g aliquots of the samples were extracted consecutively twice with 25 mL acetonitrile/water (70:30, v/v) on a laboratory shaker at 400 rpm for about 30 minutes. After each extraction step, the sample was centrifuged for 5 minutes at 4000 rpm and the supernatant was decanted into a 50 mL disposable centrifuge tube. An aliquot (10%) from the combined extract was evaporated to dryness using nitrogen at about 50ºC (in water bath) and then re-dissolved in methanol/water (20:80, v/v) with 0.1% formic acid. The concentrated extracts were sonicated for about 1-2 minutes and vortexed for about 15 seconds to ensure that all residues was dissolved. Prior to LC-MS/MS analysis, concentrated extracts were transferred into a HPLC vial using a syringe filter (0.45 µm PTFE). Some of the samples were diluted with methanol/water (20:80, v/v) and 0.1% formic acid to reach lower concentrations falling into the range of the calibration curve.

The analytical method achieves a limit of quantification (LOQ) of 0.001 mg kg^{-1} and a limit of detection (LOD) of 0.0003 mg kg^{-1} for cis-DCVA.

4. Calculation of the degradation rate

Kinetic evaluation was performed in order to derive degradation parameters as triggers for additional work (trigger endpoints) as well as modeling endpoints. Kinetic analysis and calculation of $DegT_{50}$ and $DegT_{90}$ values was performed following the recommendations of the FOCUS Kinetics workgroup [*FOCUS (2006)*].

The software package KinGUI (version 2.2012.320.1629) was used for parameter fitting [*SCHÄFER et al. (2007)*].

Modeling strategy

The kinetic models employed for this evaluation were described by FOCUS [*FOCUS (2006)*].

Trigger endpoints were derived from the kinetic model that provides the best fit to the measured data, generally indicated by the lowest χ^2 - error. Modeling endpoints were derived from the SFO model.

The appropriateness of the distinct kinetic model to describe soil degradation was tested by visual assessment. Furthermore, a kinetic model was considered appropriate for deriving trigger or modeling endpoints of χ^2 – error value was low (ideally below 15%).

Experimental data used for kinetic analysis

The experimental data were derived from the study reports and adjusted according to FOCUS [*FOUCS (2006)*].

The datasets submitted to kinetic analyses are given in Table 7.1.2.1.2-7.

II. RESULTS AND DISCUSSION

The three soils were incubated at (20 ± 2)°C and soil moisture of approximately 40 % of the maximum water holding capacity. A nominal application rate of 0.160 mg a.i./kg dry soil was used. The extractable residues at day 0 were found to be higher than the nominal concentration and ranged from 0.170 to 0.176 mg/kg dry soil. This corresponds to mean recovery values at day 0 of 107.2 %, 108.4 % and 109.1 % for Li10, LUFA 2.2 and LUFA 5M, respectively. The degradation in each soil was followed for 41 days, with the exception of LUFA 2.2 soil, which was only followed for 31 days.
Procedural recoveries were determined for each soil and sampling date from day 1 onwards in triplicate. Overall mean recoveries were 93% (Li10), 97% (LUFA 2.2) and 99% (LUFA 5M). A potential matrix effect was investigated for all soils and was found to be below 10% in all cases.

Residues of the test item extracted from soil after given incubation periods are summarized in Table 7.1.2.1.2-8.

The calculated degradation parameters and kinetic endpoints of cis-DCVA for use as triggers for additional work and for modeling are summarized in the following table (Table 7.1.2.1.2-9)

For the evaluated soil degradation experiments, the visual assessment and the goodness-of-fit statistics show plausible fits. Therefore, the resulting $DegT_{50}$ / DT_{50} values can be considered reliable.

Table 7.1.2.1.2-9: cis-DCVA trigger and modeling endpoints

Soil	Kinetic model	χ^2 error [%]	$DegT_{50}$ [d]	$DegT_{90}$ [d]
Li 10	SFO	12.16	13.5	44.96
Lufa 2.2	SFO	4.1	4.7	15.7
Lufa 5M	SFO	12.53	11.1	36.8

Normalization of laboratory degradation endpoints to reference conditions

Since for environmental fate modeling soil $DegT_{50}$ values at reference conditions (temperature of 20°C and soil moisture at field capacity, i.e. pF2) are required, the modeling endpoints ($DegT_{50}$) reported in CA 7.1.1.1/1 [*BASF Doc ID 2014/1000641*], CA 7.1.2.1.1/4 [*BASF Doc ID 2014/1159491*], CA 7.1.2.1.2/1 [BASF Doc ID 2015/3003981] and CA 7.1.2.1.2/2 [BASF Doc ID 2015/3003982] were normalized as described in CA 7.1.2.1.1.

Parameters included in the normalization procedure and the resulting normalized $DegT_{50}$ values for modeling are summarized in Table 7.1.2.1.2-10.

Table 7.1.2.1.2-10: Normalization of alpha-cypermethrin metabolites M310I017, DCVA, and 3-PBA $DegT_{50}$ values to reference conditions

CA 7.1.2.1.3 Anaerobic degradation of the active substance

Information on the rate of degradation under anaerobic conditions is provided in CA 7.1.1.2: Staudenmaier H. Kuhnke G., 2014: Anaerobic soil metabolism of alpha-cypermethrin (BAS 310 I) 2013/1386602.

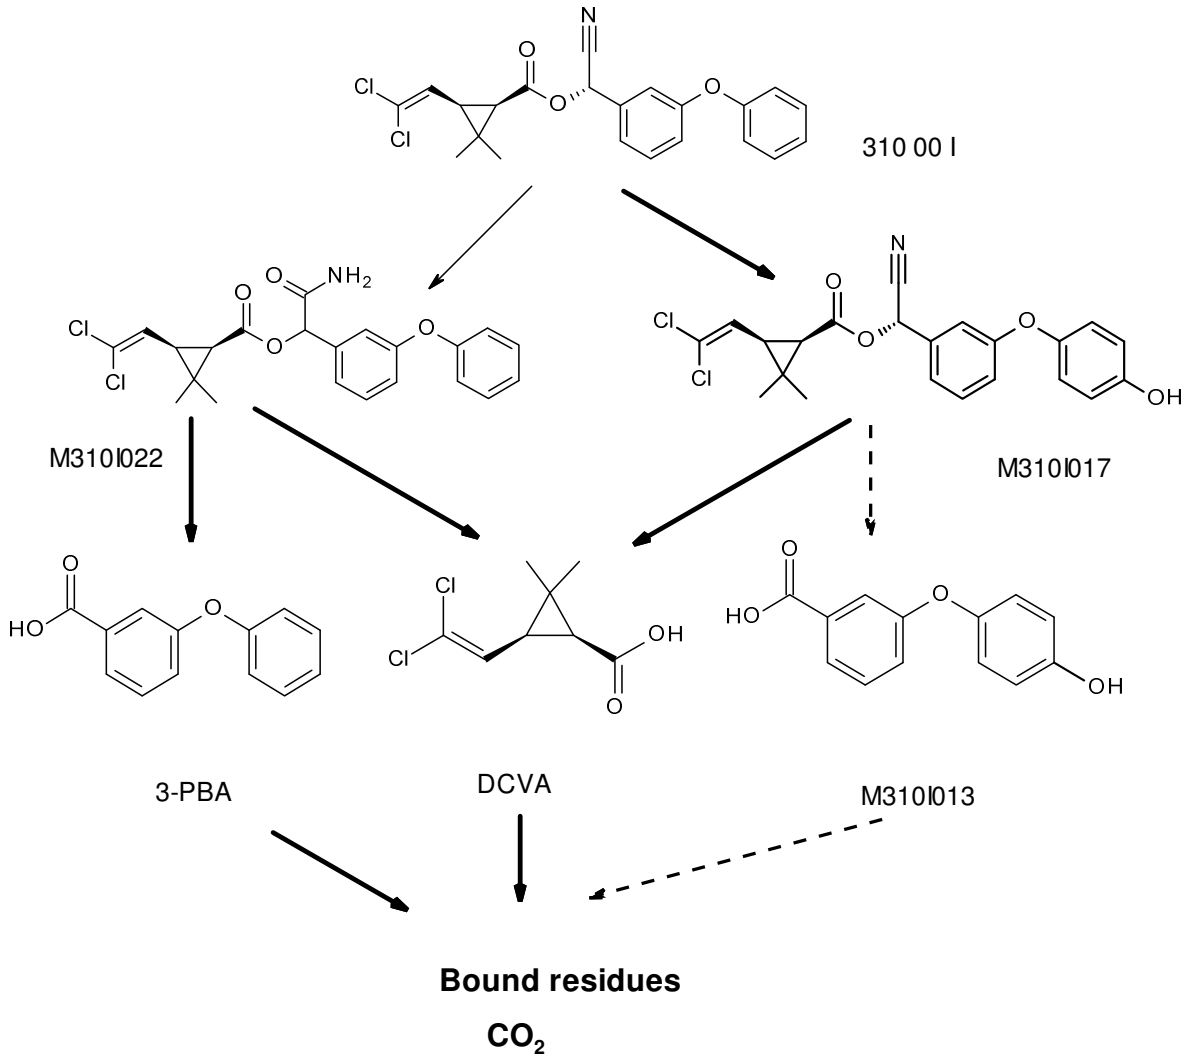
CA 7.1.2.1.4 Anaerobic degradation of metabolites, breakdown and reaction products

No study was performed for metabolites. Information on the rate of degradation of metabolite M310I017 under anaerobic conditions is provided in CA 7.1.1.2: Staudenmaier H. Kuhnke G., 2014: Anaerobic soil metabolism of alpha-cypermethrin (BAS 310 I) 2013/1386602. DCVA and 3-PBA are also aerobic metabolites and information on their aerobic egradation is available. No metabolites specific to anaerobic conditions were detected.

Metabolic pathway of alpha-cypermethrin in soil

Based on the aerobic and anawerobic metabolism studies, as well as the soil photolysis the following route of degradation is proposed for alpha-cypermethrin:

Figure 7.1.2.1.4-1: Route of degradation of alpha-cypermethrin in soil



CA 7.1.2.2 Field studies

Numerous field dissipation studies were conducted either with cypermethrin or alpha-cypermethrin. An overview is presented in Table Table 7.1.2.2-1. These studies were no longer considered adequate and new field trials were performed. The study on six sites in the EU was conducted according to new guidance using a sand cover to exclude photolytic effects or volatilization. This study was used to derive modelling endpoints. To obtain a more realistic picture of the behaviour of alpha.cypermethrin in soil for persistence endpoints, a study conducted in the US was submitted.

Trials performed with alpha-cypermethrin
(All trials non GLP.)
1. Forbes S. (1983) Analysis of soil from UK for residues of WL 85871 - Soil persistence trial - First year
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a sandy clay soil in Reculver (UK). Application done in August. Poor quality report, method not suitable to determine 10% of initial, therefore data are not suitable to derive endpoints.

2. Forbes S. (1983) Analysis of soil from UK for residues of WL 85871 - Soil persistence trial - Second year
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a sandy clay soil in Reculver (UK). Second application at the same site. Application done in August. Poor quality report, only 5 data points, therefore data are not suitable to derive endpoints.

3. Forbes S. (1985) Analysis of soil from UK (Reculver) for residues of FASTAC (WL 85871) - Soil persistence trial - Third year
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a sandy clay soil in Reculver (UK). Third application at the same site. Application done in August. Samples were shipped at ambient temperature. Poor quality report. Therefore data are not suitable to derive endpoints.

4. Bosio P.G. (1983) Residues of WL 85871 and metabolites in soil from UK treated with FASTAC - 1981/82 trials -
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a loam in Hoath (UK). Application done in August. Poor quality report, only three values above LOQ, metabolites not detected. Therefore data are not suitable to derive endpoints.

5. Forbes S. (1983) Analysis of soil from UK (Hoath) for residues of FASTAC (WL 85871) - Soil persistence trial - Second year -
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a loam in Hoath (UK). Application done in August, second application to the same site. Poor quality report, only five values above LOQ. Therefore data are not suitable to derive endpoints.

6. Forbes S. (1983) Analysis of soil from UK (Hoath) for residues of FASTAC (WL 85871) - Soil persistence trial - third year -
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a loam in Hoath (UK). Application done in August, third application to the same site. Poor quality report, inconsistent resukts in the three trial years. Therefore data are not suitable to derive endpoints.

7. Forbes S. (1983) Analysis of soil from UK (Coates) for residues of WL 85871 - Soil persistence trial - Second year year
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a now described as silty clay soil in Coates (UK). Second application after one year on the same site. Poor quality of report. The soil is not well described, therefore data are not suitable to derive endpoints.

8. Coveney P. C. (1986) Analysis of soil from UK (Coates) for residues of WL 85871 - Soil persistence trial - Third year
Short description of a highly overdosed (0.5 kg ha^{-1}) dissipation trial in a peat soil in Coates (UK). Application done in June. Poor quality report. The soil is not well described, therefore data are not suitable to derive endpoints.

CA 7.1.2.2.1 Soil dissipation studies

Report:	CA 7.1.2.2.1/1 Geschke, S., 2015 Freezer Storage Stability of the Diastereomeric Forms of BAS 311 I and its Metabolites 3-Phenoxybenzoic acid and DCVA (Cis and Trans Isomers) in Soil ~~2015/1249075~~ 2015/1249074
Guidelines:	EC guideline 7032/VI/95 rev. 5 OECD 506 (2007) EPA guideline OPPTS 860.1380
GLP:	yes

Executive Summary

In the present study, the storage stability of cypermethrin isomers cis 1, cis 2, trans 3 and trans 4) and its metabolites 3-phenoxybenzoic acid and DCVA (cis and trans isomers) was investigated by fortifying untreated soil samples (six different soil types) with the test items and analysing the samples after different periods of storage (0, 30, 60, 120, 240, 360, 630, and 720 days) in the deep-freezer.

Description of the Analytical Method

Residues of cypermethrin isomers were extracted with 0.1 % formic acid in acetonitrile. An aliquot of the extract was evaporated to dryness and reconstituted in 0.1 % formic acid in acetonitrile/demineralized water (1:1, v/v) prior analysis by HPLC with MS/MS detection.
Residues of 3-phenoxybenzoic acid (3-PBA) and DCVA isomers cis and trans were extracted twice with acetonitrile/ demineralized water (70:30, v/v). An aliquot of the extracts was evaporated to dryness and reconstituted in 0.1 % formic acid in methanol/ demineralized water (20:80, v/v) prior to analysis by HPLC with MS/MS detection.

Untreated soil control samples were analyzed for residues of the analytes. Residues were below the limit of detection (< 30 % of LOQ).

Analysis of Storage Stability Samples for cypermethrin isomers (values reported as % of initial)

~~After~~ During 727 days of storage, 80 % to 100 % of the initial concentration of cypermethrin isomer cis 1 was found in spiked soil samples fortified with the mixture of the cis isomers. In case of the cis 2 isomer the range was 79% to 103%.

~~After~~ During 727 days of storage 75% to 114% of the initial concentration of the trans 3 isomer was found in samoles spiked with a mixture of both trans isomers. In case of trans 4 isomer the range was 80% to 107%.

~~After~~ During 727 days of storage, the residues of alpha-cypermethrin ~~were~~ remained in the range of 82% to 112 % of the initial concentration.

Analysis of Storage Stability Samples for PBA and DCVA (CIS and TRANS isomers)

~~After~~ During 721 days of storage, residues ~~were still~~ remained in the range of 87 % to 118 % of the initial concentration of cis-DCVA isomer in spiked soil samples fortified with DCVA isomers. The range for the trans-DCVA isomer was 74% to 110% of the initial concentration.

~~After~~ During 721 days of storage residues of 3-PBA ~~were still~~ remained in the range of 88% to 149 % of the initial concentration of 3-PBA.

According to EC guideline 7032/VI/95 and U.S. EPA guideline OPPTS 860.1380, residues can be regarded as stable if the mean recovery at a given storage period does not fall below 70 % of the initial value. The results indicate that alpha-cypermethrin, its isomers and metabolites were stable under deep-frozen (≤ -18°C) conditions in soil for at least 727 days of storage.

B. STUDY DESIGN

1. Experimental Conditions

The storage stability of BAS 311 I (cypermethrin isomers cis-1, cis-2, trans-3, and trans-4) and its metabolites 3-phenoxybenzoic acid and DCVA (cis and trans isomers) was investigated by fortifying untreated soil samples (six different soil types) with the test items (cypermethrin cis isomers (cis-1/cis-2 = 45:55), cypermethrin trans isomers (trans-3 : trans-4 = 43.5 : 56.5), DCVA (mixture of cis/trans Isomers = 51.5:48.5), alpha-cypermethrin, and 3-PBA) and analysing the samples after different periods of storage (cis I, cis II, trans III, trans IV, and alpha-cypermethrin: 0, 31, 62, 122, 241, 361, 634, and 727 days; DCVA and 3-PBA: 0, 31, 60, 123, 241, 360, 633, and 721 days) at -18°C.

2. Description of analytical procedures

For determination of BAS 311 I (cypermethrin isomers cis-1, cis-2, trans-3, and trans-4) and its metabolites 3-PBA and DCVA (cis and trans isomers), soil samples were analysed by method R0034/01. The limit of quantification (LOQ) was 0.001 mg kg^{-1} for each analyte.

Determination of cypermethrin isomers cis-1, cis-2, trans-3, and trans-4

Residues of cypermethrin isomers cis-1, cis-2, trans-3, and trans-4 were extracted with 0.1% formic acid in acetonitrile. An aliquot of the extract was evaporated to dryness and reconstituted in 0.1% formic acid in acetonitrile/demineralized water (1:1, v/v) prior analysis by HPLC-MS/MS detection.

Determination of 3-phenoxybenzoic acid (3-PBA) and DCVA isomers cis and trans

Residues of 3-phenoxybenzoic acid (3-PBA) and DCVA isomers cis and trans were extracted twice with acetonitrile/ demineralized water (70:30, v/v). An aliquot of the extracts was evaporated to dryness and reconstituted in 0.1% formic acid in methanol/ demineralized water (20:80, v/v) prior to analysis by HPLC-MS/MS detection.

The analytical method used for determination of residues of cypermethrin isomers cis-1, cis-2, trans-3, and trans-4, 3-PBA, and DCVA isomers cis and trans in soil samples was fully validated during a parallel GLP-compliant study (Geschke, 2014, S12-01863).

The method was concurrently validated with analyses of stored soil samples within the summarized study. Procedural recovery samples were obtained by fortification (10 x LOQ) of untreated soil samples with cypermethrin isomers cis-1, cis-2, trans-3, and trans-4, 3-PBA, and DCVA isomers cis and trans test items prior to extraction.

II. RESULTS AND DISCUSSION

Procedural recoveries for cypermethrin isomers cis-1, cis-2, trans-3, and trans-4

Overall mean recoveries ranged from 89% to 113% for cypermethrin isomer cis-1 for soil L120555 to L120560 at a fortification level of 0.009 mg kg^{-1} (n = 16); from 93% to 113% for cypermethrin isomer cis-2 for soil L120555 to L120560 at a fortification level of 0.011 mg kg^{-1} (n = 16); from 91% to 114% for cypermethrin isomer trans-3 for soil L120555 to L120560 at a fortification level of 0.0087 mg kg^{-1} (n = 16), and from 95% to 111% for cypermethrin isomer trans-4 for soil L120555 to L120560 at a fortification level of 0.0113 mg kg^{-1} (n = 16). The maximum relative standard deviation of 11.9% at the given fortification levels was observed for the four different isomers. The results are shown from Table 7.1.2.2.1-1 to Table 7.1.2.2.1-5.

Analysis of storage stability samples for cypermethrin isomers cis-1, cis-2, trans-3, and trans-4

After 727 days of storage, 83% (L120555), 83% (L120556), 89% (L120557), 82% (L120558), 84% (L120559) and 85% (L120560) of the initial concentration of cypermethrin isomer cis-1 was found in spiked soil samples fortified with the mixture of the cis isomers (cis-1/ cis-2 = 45:55).

After 727 days of storage, 89% (L120555), 90% (L120556), 90% (L120557), 88% (L120558), 89% (L120559) and 91% (L120560) of the initial concentration of cypermethrin isomer cis-2 was found in spiked soil samples fortified with mixture of the cis isomers (cis-1/ cis-2 = 45:55).

After 727 days of storage, 86% (L120555), 88% (L120556), 85% (L120557), 75% (L120558), 83% (L120559) and 84% (L120560) of the initial concentration of cypermethrin isomer trans-3 was found in spiked soil samples fortified with the mixture of the trans isomers (trans-3/ trans-4 = 43.5:56.5).

After 727 days of storage, 86% (L120555), 88% (L120556), 88% (L120557), 81% (L120558), 80% (L120559) and 86% (L120560) of the initial concentration of cypermethrin isomer trans-4 was found in spiked soil samples fortified with mixture of the trans isomers (trans-3/ trans-4 = 43.5:56.5).

After 727 days of storage, 89% (L120555), 90% (L120556), 86% (L120557), 88% (L120558), 88% (L120559) and 88% (L120560) of the initial concentration of cypermethrin isomer cis-2 was found in spiked soil samples fortified with the test item alpha-cypermethrin.

Recovery rates for storage samples is reported not corrected for procedural recoveries and recovery obtained at time zero is set to 100%. The results are shown from Table 7.1.2.2.1-1 to Table 7.1.2.2.1-5.

Procedural recoveries for 3-PBA and DCVA (cis and trans isomers)
Overall mean recoveries were 74% to 110% for 3-PBA for soil L120555 to L120560 at a fortification level of 0.01 mg kg^{-1} (n = 16), 75% to 100% for DCVA isomer cis for soil L120555 to L120560 at a fortification level of 0.0103 mg kg^{-1} (n = 16), and 79% to 105% for DCVA isomer trans for soil L120555 to L120560 at a fortification level of 0.0097 mg kg^{-1} (n = 16). The maximum relative standard deviation of 12.8% at the given fortification levels was observed for the three analytes. The results are shown from Table 7.1.2.2.1-6 to Table 7.1.2.2.1-8.

Analysis of Storage Stability Samples for PBA and DCVA (cis and trans isomers)
After 721 days of storage, 87% (L120555), 96% (L120556), 88% (L120557), 93% (L120558), 107% (L120559) and 93% (L120560) of the initial concentration of DCVA isomer cis was found in spiked soil samples fortified with the test item DCVA isomers (cis/ trans = 51.5:48.5).
After 721 days of storage, 75% (L120555), 82% (L120556), 91% (L120557), 88% (L120558), 87% (L120559) and 84% (L120560) of the initial concentration of DCVA isomer trans was found in spiked soil samples fortified with the test item DCVA isomers (cis/ trans = 51.5:48.5).
After 721 days of storage, 97% (L120555), 95% (L120556), 92% (L120557), 114% (L120558), 103% (L120559) and 101% (L120560) of the initial concentration of 3-PBA was found in spiked soil samples fortified with the test item 3-PBA.

Recovery rates for storage samples is reported not corrected for procedural recoveries and recovery obtained at time zero is set to 100%. The results are shown from Table 7.1.2.2.1-6 to Table 7.1.2.2.1-8.

III. CONCLUSION

According to EC guideline 7032/VI/95 and U.S. EPA guideline OPPTS 860.1380, residues can be regarded as stable if the mean recovery at a given storage period does not fall below 70% of the initial value. The results show that cypermethrin isomers cis-1, cis-2, trans-3, and trans-4 are stable under deep-frozen conditions in (≤ -18°C) soil for at least 721 days of storage.

According to EC guideline 7032/VI/95 and U.S. EPA guideline OPPTS 860.1380, residues can be regarded as stable if the mean recovery at a given storage period does not fall below 70% of the initial value. The results indicate that 3-PBA and DCVA isomers cis and trans are stable under deep-frozen (≤ -18°C) conditions in soil for at least 727 days of storage.

Report:	CA 7.1.2.2.1/2 Jacobsen B., Warren R., Robaugh D.A., Schmitt J.L., Perez S.R., Saha M., 2013a Terrestrial Field Dissipation study of the Insecticide Alpha-Cypermethrin (BAS 310 I) Following Broadcast Application of BAS 310 65 I Using a Row Crop Use Pattern 2013/7002604
Guidelines:	EPA OPPTS 835.6100
GLP:	yes (certified by United States Environmental Protection Agency, USA)

Executive Summary

The purpose of this study was to determine the mobility and persistence potential of alpha-cypermethrin (BAS 310 I) when applied under field conditions as a capsule suspension (CS) formulation to a bare soil plot. Field sites in Louisiana, Oklahoma, New York, and California were selected for this study and are geographically appropriate for the proposed use pattern of BAS 310 65 I in the U.S.. The BAS 310 65 I formulation utilized in this study is a capsule suspension formulation containing 100 g a.s. per liter.

The experiment was carried out in accordance with the terrestrial field dissipation requirements as outlined in the US EPA Fate, Transport and Transformation Test Guideline, OPPTS 835.6100: Terrestrial Field Dissipation.

At each test site, the designated treated plot received three uniform broadcast applications of BAS 310 65 I, with a targeted 7-day interval between applications, at a target rate of 28 g a.s. ha^{-1} per application, the maximum proposed label use rate. At each site there were two test plots: one treated bare soil plot and one control bare soil plot. The treated plot at each test site was divided into three replicate subplots. The plots were kept in a bare soil condition throughout the study. Rainfall was supplemented with irrigation at all four of the test sites.

The application rate was verified at each application at each test location by placing 10 environmental extraction disks in each of the three replicate subplots just prior to each application. Considering all sites, the overall mean recovery of alpha-cypermethrin (cis-2 isomer) plus the cis-1 isomer (a transformation product) from the extraction disk application monitor samples was 81% of the target (considering applications 1, 2, and 3).

Five soil core samples were taken from the soil surface to a depth of 36 inches (about 91 cm) at various times following each application and the final (third) application from each replicate subplot. Soil samples were targeted for collection at T1 (immediately after first application), T1+1, T1+3, -T2, T2, -T3, T3 and then 1, 3, 6, 10, 20, 30, 60, 90, 120, 180 and 270 days after last application (DALA). Soil cores were sectioned into segments of 0-2, 2-4, and 4-6, 6-12, 12-18, 18-24, 24-30 and 30-36 inches (about 0-5, 5-10, 10-15, 15-30, 30-46, 46-61, 61-76 and 76-91 cm). Core segments were composited by depth for each replicate subplot.

Soil samples were extracted with acetonitrile and extracts were analyzed for alpha-cypermethrin (cis-2 isomer) as well as the other cypermethrin isomers cis-1, trans-3, and trans-4 in order to evaluate potential isomer interconversion. Sample extracts were also analyzed for the soil transformation products cis- and trans-DCVA, and 3-PBA. High Performance Liquid Chromatography coupled with tandem mass spectrometry (HPLC-MS/MS) analytical method was used with a limit of quantification of 0.001 ppm and limit of detection of 0.0002 ppm for each analyte.

Analytical dry weight residue concentrations, undisturbed soil bulk density values, and segment lengths were used to calculate the mass of each analyte in the core segments on a gram per hectare basis. The metabolite values (3-PBA, cis-DCVA, and trans-DCVA) were converted to alpha-cypermethrin equivalent mass (by multiplying for the appropriate molecular weight factor). Total mass values of each analyte were used to determine the rate of dissipation of the analytes over time.

First-order (SFO) kinetic fits were selected to represent the dissipation of the sum of isomers at the California, Louisiana, and Oklahoma sites, while the biphasic FOMC model was selected for the New York site. Dissipation of the sum of isomers was rapid at all four sites. The $DisT_{50}$ values ranged from 3.4 days to 6.3 days with a median of 5.0 days, an average of 4.9 days, and a standard deviation of 1.4 days. The $DisT_{90}$ values ranged from 13.4 to 27.9 days with a median of 20.3 days, an average of 20.5 days, and a standard deviation of 5.9 days.

Metabolites 3-PBA, cis-DCVA, and trans-DCVA were observed at all four sites. Metabolite dissipation was characterized by simple calculation of the observed $DisT_{90}$. The interval between the maximum average observed level and the time at which the observed average dissipated to ≤ 10% of the maximum was determined. The maximum average observed level of 3-PBA ranged from 2.5 to 10% with an average of 6.0%. The observed $DisT_{90}$ of 3-PBA ranged from 5 to 37 days with an average of 23 days. The maximum average observed level of cis-DCVA ranged from 1.5 to 2.9% with an average of 2.1%. The observed $DisT_{90}$ of cis-DCVA ranged from 9 to 60 days with an average of 24 days. The maximum average observed level of trans-DCVA ranged from 0.2 to 1.7% with an average of 0.9%. The observed $DisT_{90}$ of trans-DCVA ranged from 1 to 9 days with an average of 6 days. The maximum average observed level of the sum of DCVA isomers ranged from 1.7 to 3.8% with an average of 3.0%. The observed $DisT_{90}$ of the DCVA isomer sum ranged from 9 to 60 days with an average of 24 days. These data indicate that the metabolites of alpha-cypermethrin were not persistent with 90% dissipation from peak average observed levels occurring within approximately one month.

Alpha-cypermethrin dissipated by aerobic soil processes and formed expected transformation products 3-PBA, cis-DCVA, and trans-DCVA at each site. Limited conversion of alpha-cypermethrin (cis-2 isomer) to other cypermethrin isomers (cis-1, trans-3, trans-4) was observed. While the cis-1 isomers were most prevalent, maximum average levels reached only 2.8 to 5.0% of the amount applied. Neither alpha-cypermethrin nor degradation products appeared to be inherently susceptible to leaching. They were not detected in soil below 2-4 inch (about 10 cm) soil depth at any of the four locations, even if site hydrologic conditions were generally favorable for leaching at all four sites. Overall, the aerobic soil transformation was the primary dissipation process in combination with a very limited leaching mobility.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test item (formulation):	BAS 310 65 I
Active ingredient:	alpha-cypermethrin (Reg. No. 4078193)
Chemical name (IUPAC):	Racemate of (S)-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Molar mass:	416.3 g mol^{-1}
Batch No.:	144315 (containing 99.3 g alpha-cypermethrin L^{-1})
Type of formulation:	CS

2. Test sites

The dissipation of alpha-cypermethrin and its metabolites 3-PBA, cis-DCVA, and trans-DCVA under field conditions was investigated at four sites in the U.S. The site characteristics including the basic soil parameters of the corresponding soil horizons are presented in Table 7.1.2.2.1-9 and Table 7.1.2.2.1-10.

The selected fields represented typical regions of agricultural practice and had been under cultivation for many years. The sampling sites were fallow prior to the study. No product containing alpha-cypermethrin had been used on the test plots in the last three years.

B. STUDY DESIGN

1. Experimental conditions

Each trial area was divided into two plots. One plot (about 47-151 m²) was used as control plot (untreated) and the second plot (about 348-557 m²) was treated with the test item. Treated plots consisted of three subplots (A, B, C) that were assigned for replicates. The size of each treated replicate (subplot) was 139.4 m^2 (R120066), 116.2 m² (R120067), 174.1 m² (R120068), and 186.1 m² (R120069), respectively. The control plot was not subdivided, but was separated from the treated plot by a buffer zone of at least 15 m width.

The product, formulated as a CS, was broadcast applied to bare soil in three applications, each at a nominal rate of 28 g a.s. ha^{-1}. Depending on the trial site, the applications were conducted from the end of Jun-2012 until the end of Jul-2012 using a calibrated boom sprayer. The actual application rates determined by quantifying the amount of spray discharged ranged from 27 to 29 g a.s. ha^{-1}. Details of the application are presented in Table 7.1.2.2.1-11.

Three methods were used to verify the application of alpha-cypermethrin at each trial site: calibrated sprayer pass time calculations, application verification device analysis, and determination of the total mass of alpha-cypermethrin present in application day soil samples. Details are given in the study report.

Table 7.1.2.2.1-11: Application parameters of field trial sites treated with alpha-cypermethrin

Trial Location	Test item/ Nominal content/ Formulation type	Application method	No. of applications	Application rate per treatment			No. of treated replicates	Application date
				Nominal [g a.s. ha^{-1}]	Actual [g a.s. ha^{-1}]	Dose verification*

No tillage was performed during the course of the study from first to last sampling and no crops were grown throughout any of the trials. The plots were kept free of vegetation via the application of glyphosate, glufosinate, and paraquat.

Climatic conditions were based on records of appropriate weather stations located at a distance of 8-88 km from each site. Irrigation was applied to supplement normal precipitation so that the plots would receive 120% of historical average rainfall for the study period.

A summary of monthly weather data (temperature and precipitation, as well as volumes of the supplementary irrigation) is presented in Table 7.1.2.2.1-12.

n.d. = Not determined

2. Sampling

Replicate soil samples were taken randomly at different sampling intervals (see Table 7.1.2.2.1-13) with a soil corer, starting one day prior to the first application until about 270 days after the last application. Fifteen cores were collected in the treated plot (5 cores for each subplot) and also 15 cores were taken from the control plot. A soil depth of up to 36 inches (~ 91 cm) was taken for each soil. Detailed sampling intervals are presented in Table 7.1.2.2.1-13.

Table 7.1.2.2.1-13: Summary of sampling intervals of the treated plots at each field trial site

Trial	Location	Sampling intervals [days]
R120066	Louisiana, USA	-T1, T1; T1+1; T1+3, -T2, T2, -T3, T3, [1, 3, 6, 10, 20, 30, 63, 91, 120, 202, 272]*
R120067	Oklahoma, USA	-T1, T1; T1+1; T1+3, -T2, T2, -T3, T3, [1, 3, 6, 10, 20, 30, 63, 92, 125, 181, 270]*
R120068	New York, USA	-T1, T1; T1+1; T1+3, -T2, T2, -T3, T3, [1, 3, 6, 10, 20, 30, 59, 90, 120, 177, 270]*
R120069	California, USA	-T1, T1; T1+1; T1+3, -T2, T2, -T3, T3, [1, 3, 6, 10, 20, 30, 59, 90, 120, 181, 269]*

T = Day of application (immediately after treatment)
-T = Day before the first application
* Sampling dates refer to the day of the last application (T3)

Samples from untreated soils were collected from the control plot on five occasions one day before the application (-T1) and 3, 10, 30 and 63 days (for trials R120066 and R120067) or 59 days (for trials R120068 and R120069) after the last application.
At each sampling interval in the treated plots, five 0-6 inches (0-15 cm) and five 6-36 inches (15-91 cm) soil cores were collected for each subplot (for a total of 15 0-6 inches and 15 6-36 inches cores), except on T1 when only 0-6 inches cores were collected, and on the day of each application (T1, T2, and T3), when a duplicate set of 0-2 inches cores was taken.

At –T1 in control plots, five 0-6 inches and five 6-36 inches cores were taken from three randomly selected sampling blocks for a total of 15 cores, while at subsequent sampling events five 0-6 inches and five 6-36 inches were selected from one randomly selected sampling block (for a total of 10 cores).
The specimens were pooled according to soil depth. Immediately after sampling and before freezing, all soil cores collected with the soil probe were segmented to 0-2, 2-4 and 4-6 inches, and 6-36 inches samples were cut into 6-inch segments and pooled by depth.

All soil specimens were placed into freezer storage at about -18°C and remained frozen until processing or analysis of the samples.

3. Description of analytical procedure

The analysis for alpha-cypermethrin, cypermethrin, trans-3, and trans-4-cypermethrin residues in soil samples and analysis for alpha-cypermethrin and cypermethrin residues in application verification and shipping verification samples was performed by Pyxant Labs Inc. (Colorado Springs, CO, USA). Analysis of the metabolites cis-DCVA, trans-DCVA, and 3-PBA was conducted by ADPEN Laboratories Inc. (Jacksonville, FL, USA).

Analysis of soil core samples for alpha-cypermethrin, cypermethrin, cis-DCVA, trans-DCVA, and 3-PBA was conducted using the BASF analytical method R0034/01. Details on the method are given in the study report.

Analysis of the application verification (AV) samples with environmental extraction disks (one of the three verification methods mentioned above) was conducted for residues of alpha-cypermethrin (cis-2 isomer) plus the cis-1 isomer, which was evident in the AV samples. The extraction disks were analyzed directly by extracting with acetonitrile on a solid phase extraction (SPE) vacuum manifold. The combined extracts were further diluted with 50:50 acetonitrile/water (v/v) with 0.1% formic acid and analyzed by HPLC-MS/MS.

For each site, three composite samples, one from each replicate treated plot, were analyzed at each sampling interval and depth. On application days (Tl, T2, and T3) three additional composite samples (0-2 inches (about 0-5 cm) depth only), one from each replicate treated plot, were also collected for analysis. Composite samples were generally analyzed once, however, selected samples were analyzed multiple times.

For alpha-cypermethrin and isomers, a 5 g soil sample was extracted by shaking once with 50 mL of 0.1% formic acid in acetonitrile. The extracts were concentrated to dryness and then diluted with 50:50 acetonitrile/water (v/v) with 0.1% formic acid. For the metabolites cis-DCVA, trans-DCVA, and 3-PBA, a 5 g soil sample was extracted by shaking twice with 25 mL acetonitrile/water (70:30, v/v). An aliquot (10%) from the combined extract was evaporated to dryness and then dissolved in methanol/water (20:80, v/v) with 0.1% formic acid.

All residues were determined using HPLC-MS/MS in the positive ion mode. The limit of quantitation was 0.001 mg kg^{-1} (ppm) and the limit of detection was 0.0002 mg kg^{-1} (ppm) for all analytes in soil. Soil results were reported on a dry weight basis for residue determination.

The shipping verification samples were analyzed for residues of alpha-cypermethrin (cis-2 isomers) plus the cis-1 isomer, according to BASF method R0034/01. The shipping verification samples (20 g each, weighed in the field) were extracted with 0.1% formic acid in acetonitrile. Following extraction, alpha-cypermethrin and cis-1 isomer residues were determined by HPLC-MS/MS.

4. Storage stability experiments

The stability of alpha-cypermethrin and its transformation products in frozen soil has been previously demonstrated in three studies [*ARCHER S. AND FORBES, S. (1985): Storage stability of FASTAC (WL85871) residues in crops and soil deep frozen at -18°C, BASF DocID 1985/7001362; HITCHINGS, E.J. (1989a): Storage stability of residues of the pyrethroid metabolite WL44607 added to soils deep frozen at -l8°C, BASF DocID 19817001056; HITCHINGS, E.J. (1989b): Storage stability of residues of the RIPCORD metabolite WL44776 added to soils deep frozen at -18°C, BASF DocID 1981/7001057*].

The freezer storage stability of alpha-cypermethrin, DCVA, and 3-PBA in soils collected from the four trial sites was evidenced in another study *[CA 7.1.2.2.1/1, BASF DocID 2014/1152598*] and will cover the interval needed for this study.

5. Kinetic evaluation

In order to generate a conservative kinetic assessment for alpha-cypermethrin (cis-2 isomer), the g ha^{-1} values for all isomers of the parent (cis-1, cis-2, trans-3, and trans-4, i.e. the cypermethrin isomers) were summed at each sampling time. The dissipation of the sum of isomers was assessed following the peak average level following the last application.

The guidance of the FOCUS work group on degradation kinetics [*FOCUS (2006*] was used as the general basis for conducting the kinetic analysis, statistical assessment, and selection of the best fit kinetic model. The software package KinGUII (version 2.2012.202.925) was used for parameter fitting. Decline of the isomer sum was evaluated using a two-parameter single first-order (SFO) model and the three-parameter first-order multi compartment (FOMC) biphasic model. Where FOMC provided a better fit, the four-parameter double first-order in parallel (DFOP) biphasic model was additionally assessed.

The goodness-of-fit of the kinetic models was assessed by visual inspection and statistical measures recommended by the FOCUS guidance. The goodness-of-fit used for the identification of the best-fit kinetic model was the χ^2 minimum error level. The kinetic endpoints ($DisT_{50}$ and $DisT_{90}$ values) are reported in Table 7.1.2.2.1-19 for the kinetic models which were selected based on statistical and visual assessment. The reliability of individual parameters was judged by means of a single-sided t-test.

II. RESULTS AND DISCUSSION

1. Application verification

The application verification samples (environmental extraction disks) were analyzed for alpha-cypermethrin (cis-2 isomer) plus the cis-1 isomers, which were evident in the samples. The application verification sample recoveries were corrected for procedural recoveries. The mean percent recovery from the application verification samples was 81% of the test item for all trial sites. Mean percent recoveries of the individual trial sites are given in Table 7.1.2.2.1-14.

Table 7.1.2.2.1-14: Summary of application verification sample recoveries (n = 3) [%]

Application No.	R120066 Louisiana	R120067 Oklahoma	R120068 New York	R120069 California
T1	109±16.0	67±2.5	77±5.5	66±10.0
T2	88±15.0	83±15	91±4.9	69±4.4
T3	85±6.9	78±3.1	77±4. 2	76±12.0

2. Residues in field soil samples

Mean procedural recoveries from control soil samples fortified with alpha-cypermethrin, cypermethrin isomers, cis-DCVA, trans-DCVA, and 3-PBA at 0.001 and 0.1 ppm were generally within the acceptable range of 70-120%. In those instances where low recoveries were obtained (typically for the trans-3 and trans-4 isomers), the sample was reanalyzed in duplicate to confirm results (the average of all three results were reported). The recovery results were not corrected as apparent residues were non-detectable in the associated control samples. A summary of the individual procedural recovery results is provided in the study report.

Field soil samples taken from different depths were analyzed to a maximum of about 272 days after the last of the three applications. The analytical results are summarized in Table 7.1.2.2.1-15 to Table 7.1.2.2.1-18. All residue values presented in these tables are related to the dry weight of the soil and were not corrected for procedural recoveries. Residue concentrations are reported according to soil depth (0-2, 2-4, 4-6, 6-12, 12-18, 18-24, 24-30 and 30-36 inches, corresponding to about 0-5, 5-10, 10-15, 15-30, 30-46, 46-61, 61-76 and 76-91 cm).

Although samples were collected to a depth of 36 inches, samples below 6-12 inches were generally not analyzed due to the absence of residues in overlying segments. Residue concentrations in samples taken prior to the application (-T1) at both sites were non-detectable (< 0.0002 ppm) and were omitted from the following tables for brevity.

Table 7.1.2.2.1-15: Residues of alpha-cypermethrin and metabolites [µg kg^{-1} dry weight] in treated soil samples (mean of three replicates) – Lousiana site (R120066)

T = Application dates
n.d. = Not detected
- = Not analyzed
* Denotes instance where the mean for all replicates is < 0.0002 ppm (< LOD), but one or two replicates contained detectable residues, the maximum of which is shown.
Values > LOD (> 0.0002 ppm), but < LOQ (< 0.001 ppm) are shown in italics.

Alpha-cypermethrin was degraded significantly in all trials. The analytical data showed that about 90% of the applied amount was degraded 20 days after the last application. Quantifiable levels (> 0.001 mg kg^{-1}) of alpha-cypermethrin were only found to a depth of 2 inches (~ 5 cm). Alpha-cypermethrin was detected in soil depths > 4 inches (~ 10 cm) in trial Louisiana, New York, and California. However, measured concentrations of alpha-cypermethrin were all < LOQ.

Limited conversion of alpha-cypermethrin (cis-2) to other cypermethrin isomers (cis-1, trans-3, trans-4) was observed. While the cis-1 isomer was most prevalent, maximum average levels reached only 2.8 to 5.0% of the amount applied.

Metabolites cis- and trans-DCVA, as well as 3-PBA were detected in the upper 2 inches (~ 0-5 cm) and sporadically in soil depths of 2-4 inches (~ 5-10 cm) up to 30 days after the last application. At trial site Louisiana the trans-4 isomer of cypermethrin, cis-, and trans-DCVA were detected in samples > 60 days after application. At trial site Louisiana, metabolite cis-DCVA was detected also in soil depths from 4 to 6 inches (~ 10-15 cm) and up to 180 days after the last application in a soil depth of 2-4 inches (~ 5-10 cm). However, concentrations of cis-DCVA > 2 inches (~ 5 cm) depth were always < LOQ.

Overall, metabolites cis- and trans-DCVA were only present in small concentrations with detected concentrations always below the LOQ. Only at trial sites Oklahoma and California concentrations above the LOQ were detected in a soil depth of 0-2 inches (~ 0-5 cm).

Considerable concentrations (> LOQ) of the metabolite 3-PBA could be observed in the upper 2 inches (~ 0-5 cm) and up to 10 days after the applications. Detectable amounts of 3-PBA could be measured up to 30 days after the last application.

Leaching was assessed by analysis of soil core samples collected at multiple sampling events following each of three applications of the test substance to a depth of 36 inches (~ 91 cm). From the results it appears that leaching of alpha-cypermethrin and its metabolites can be disregarded as major dissipation route, since the active substance seems to have no potential to appear in groundwater.

The volatilization dissipation route was not evaluated since alpha-cypermethrin is classified as "nonvolatile from moist soil" using the calculation procedure specified in the OPPTS 835.6100 guideline. A vapor pressure of 7.7 x 10^{-8} Pa at 20°C, water solubility of 0.02 mg L^{-1} at 20°C, lowest soil adsorption K_d of 26492 [*Hill, A. (1993): [Benzyl-14C] WL85871 (FASTAC): Adsorption/desorption in three soils. BASF Reg. DocID 1993/7002014*], and a molecular weight of 416.3 g mol^{-1} were used in the calculation.

Surface water run off was not evaluated. Except for the Louisiana site (silt loam) surface and near surface soil textures were generally not conducive to infiltration excess and/or saturation excess runoff (sand and sandy loam) Further, field sites were nearly level (≤ 1% slope) and the protocol dictated that irrigation be managed to avoid ponding. Therefore, it is assumed that loss of water due to runoff was minor compared to infiltration and evaporation, and runoff was not considered to be a relevant dissipation route at these sites.

3. Kinetic evaluation

The calculated $DisT_{50}$ and $DisT_{90}$ values for the sum of alpha-cypermethrin (cis-2 isomer) plus other cypermethrin isomers (cis-1, trans-3, trans-4) in soil under terrestrial field conditions for each site are reported in Table 7.1.2.2.1-19. The values are based on the total mass in the sampled soil profile (0-36 inches, about 91 cm) over time.

Kinetic models were not fit to metabolite data due to the low and/or variable levels observed. Rather, dissipation of the metabolites 3-PBA, cis-DCVA, trans-DCVA, and the sum of DCVA isomers was characterized by calculation of the observed $DisT_{90}$ value. The day of the maximum average metabolite level was subtracted from the day the average level dissipated to ≤ 10% of the maximum. This interval represents the time in which 90% dissipation occurred and is used to characterize the persistence, or lack thereof, of the metabolites. The results for the metabolites are shown in Table 7.1.2.2.1-20.

Table 7.1.2.2.1-19: Summary of the kinetic evaluation of the sum of alpha-cypermethrin (cis-2) and isomers (cis-1, trans-3, trans-4)

Test site	Kinetic model	χ^2 error [%]	Best-fit endpoints	
			$DisT_{50}$ [d]	$DisT_{90}$ [d]
Louisiana	SFO	33.8	5.9	19.6
Oklahoma	SFO	6.3	6.3	20.9
New York	FOMC	13.5	3.4	27.9
California	SFO	8.4	4.0	13.4

Table 7.1.2.2.1-20: Interval from the maximum observed metabolite level to ≤ 10% of maximum ($DisT_{90}$; mean of three replicates)

Site	**Trans-DCVA**				**DCVA Sum**			
	Max [%]*	**Max DA1A**	**≤ 10% DA1A**	**$DisT_{90}$ interval [d]**	**Max [%]**	**Max DA1A**	**≤ 10% DA1A**	**$DisT_{90}$ interval [d]**
Louisiana	1.0	15	20	5	2.7	15	24	9
Oklahoma	0.7	16	23	7	3.7	16	33	17
New York	0.2	13	14	1	1.7	13	73	60
California	1.7	15	24	9	3.8	15	24	9
Average	**0.9**	**15**	**20**	**6**	**3.0**	**15**	**39**	**24**

Max = Maximum average metabolite level of n = 3 replicates (g ha^{-1}) divided by the total target application rate of alpha-cypermethrin (84 g ha^{-1}) and multiplied by 100.

DA1A = Days after first application. Alpha-cypermethrin was applied at 0, 7, and 14 DA1A at the California, Louisiana, and New York sites and 0, 6, and 13 DA1A at the Oklahoma site. The target application rate for all applications was 28 g a.s. ha^{-1}.

For each analyte and site the day of the average maximum observed level of n = 3 replicates (Max DA1A) was subtracted from the day at which the average level dissipated to 10% or less of the maximum (≤10% DA1A). This provides the interval in which 90% of the maximum average observed level had dissipated, i.e. the observed DT_{90}. For example, the maximum average 3-PBA level at the California site was observed on 15 DA1A (8.36 g ha^{-1}). The average level dropped to ≤ 10% of the maximum by 20 DA1A (0.74 g ha^{-1}). Therefore, 90% dissipation occurred within 20 – 15 = 5 days.

The average values of n = 3 replicates was used in the calculations for each site.

III. CONCLUSION

The major route of dissipation of alpha-cypermethrin under terrestrial field conditions in the bare soil was transformation by aerobic soil metabolism processes. Expected transformation products 3-PBA, cis-DCVA, and trans-DCVA were observed at levels up to 10% of the nominal 84 g a.s. ha^{-1} total application rate.

First-order (SFO) kinetic fits were selected to represent the dissipation of the sum of isomers at the California, Louisiana, and Oklahoma sites, while the biphasic FOMC model was selected for the New York site. Dissipation of the sum of isomers was rapid at all four sites. The $DisT_{50}$ values ranged from 3.4 days to 6.3 days with a median of 5.0 days, an average of 4.9 days, and a standard deviation of 1.4 days. The $DisT_{90}$ values ranged from 13.4 to 27.9 days with a median of 20.3 days, an average of 20.5 days, and a standard deviation of 5.9 days. These results were similar to those previously reported for cypermethrin at a Louisiana and California sites where the $DisT_{50}$ values ranged from 5 to 13 days following application of much higher rates (672 g a.s. ha^{-1} total).

Metabolites 3-PBA, cis-DCVA, and trans-DCVA were observed at all four sites. The maximum average observed level of 3-PBA ranged from 2.5 to 10.0% with an average of 6.0%. The observed $DisT_{90}$ of 3-PBA ranged from 5 to 37 days with an average of 23 days. The maximum average observed level of cis-DCVA ranged from 1.5 to 2.9% with an average of 2.1%. The observed $DisT_{90}$ of cis-DCVA ranged from 9 to 60 days with an average of 24 days. The maximum average observed level of trans-DCVA ranged from 0.2 to 1.7% with an average of 0.9%. The observed $DisT_{90}$ of trans-DCVA ranged from 1 to 9 days with an average of 6 days. The maximum average observed level of the sum of DCVA isomers ranged from 1.7 to 3.8% with an average of 3.0%. The observed $DisT_{90}$ of the DCVA isomer sum ranged from 9 to 60 days with an average of 24 days. These data indicate that the metabolites of alpha-cypermethrin were not persistent with 90% dissipation from peak average observed levels occurring within approximately one month.

Site hydrologic conditions were generally favorable for leaching. However, under these favorable conditions, mean residues of alpha-cypermethrin and the metabolites were not detected in soil (LOD = 0.0002 mg kg^{-1}) below the 2-4 inch (~ 5-10 cm) soil depth at any of the four locations. Neither alpha-cypermethrin nor degradation products appeared to be inherently susceptible to leaching.

Calculation of maximum occurrences of DCVA and 3-PBA from the US field dissipation study

The metabolites DCVA and 3-PBA occurred in relevant amounts in the US field dissipation study with alpha-cypermethrin [CA 7.1.2.2.1/2, *BASF DocID 2013/*7002604]. In the following, the derivation of the maximum occurrences of the metabolites in the US field dissipation study is described.

For the US study, the residue data in g p.e. ha^{-1} (p.e. = parent equivalents) given in the kinetic evaluation report (Appendix 2 of the study) were used considering the sum of isomers of alpha-cypermethrin and DCVA.

Alpha-cypermethrin was applied at three consecutive applications with a target interval of 7 days. Maximum occurrences were calculated for all trials and for each individual application event, considering the maximum amount of metabolite residues (mean of three plots) after an individual application and the respective maximum amount of parent residues (mean of three plots). The results are summarized in Table 7.1.2.2.1-21.

Table 7.1.2.2.1-21: Maximum occurrence of alpha-cypermethrin metabolites in US field dissipation study

Metabolite	Trial	Application number	Maximum amount of metabolite [g p.e. ha^{-1}] [a]	Maximum amount of parent [g ha^{-1}] [a,b]	Maximum occurrence [%]

Hoogeweg G., 2014a
Similarity of Four United States Alpha-Cypermethrin Terrestrial Field Dissipation Trial Sites to European Conditions: A Crosswalk Exercise Using ENASGIPS v2.3
2014/7003560
Guidelines: EPA OPPTS 835.6100 - supplemental
GLP: no

Executive Summary

The objective of the project was to conduct an ecoregion comparison and GIS Crosswalk for four sites of an US terrestrial field dissipation (TFD) study [*CA 7.1.2.2.1/2, BASF DocID 2013/7002604*] and to determine which locations in Europe, if any, have similar conditions. These four sites are located in California, Louisiana, New York, and Oklahoma. All work was conducted using the Organisation for Economic Co-operation and Development (OECD) Europe – North America Soil Geographic Information for Pesticide Studies (ENASGIPS) v2.3 application. Ecoregion similarity and GIS crosswalks were conducted in support of (re)registration of alpha-cypermethrin in Europe.

ENASGIPS is a component of an OECD project titled "Harmonized International Guidance for Pesticide Terrestrial Field Dissipation Studies and Crosswalk of North American and European Eco-regions". Its goal is to maximize the use of pesticide field dissipation studies by developing harmonized international guidance for conducting the studies and identifying comparable North American and European ecoregions. The underlying premise of ENASGIPS is that the field dissipation behavior of a pesticide in a region depends primarily on environmental factors, such as soils and climate. If these environmental factors are similar between regions, then field dissipation of a pesticide is also expected to be similar in those regions.

ENASGIPS compares ecoregions based on five parameters: mean annual temperature, mean annual precipitation, mean soil pH, mean soil organic carbon, and soil texture. Depending on the properties of the pesticide of interest, not all parameters may be important for determining field dissipation and a subset of these five parameters may be used to refine the ecoregion comparison. When all five parameters are used the comparison is termed "holistic". When a subset of the parameters is used the comparison is termed "weights of evidence". With either comparison approach, ecoregions are considered similar when their weighted similarity scores are 80% or higher.

Both holistic and weights of evidence ecoregion comparisons were made for the US alpha-cypermethrin terrestrial field dissipation sites using ENASGIPS. Since alpha-cypermethrin is a synthetic pyrethroid insecticide, and pyrethroids are well known to be highly sorbed to soil solids (i.e. limited leaching potential), precipitation was considered to be of low importance for explaining the field dissipation behavior of alpha-cypermethrin. Therefore, precipitation was not included in the ecoregion comparison for the weights of evidence assessment.

Results from the holistic similarity assessment show that matching ecoregions exceeding the 80% similarity level exist in Europe for the California, New York, and Oklahoma study sites. No matching ecoregions were found for the Louisiana study site using the 80% similarity criteria in the holistic assessment.

Results from the weights of evidence similarity assessment show that for each of the four US TFD study sites 4 to 13 similar ecoregions exceeding the 80% similarity level exist in Europe.

In addition to the holistic and weights of evidence ecoregion level comparisons, a GIS crosswalk exercise was also conducted using the ENASGIPS site selection tool. Ranges of weather and soil properties were derived from the US alpha-cypermethrin terrestrial field dissipation study and other data sources. Areas in Europe that fall within the defined ranges were then identified using both the holistic approach (i.e. all five variables included) and a weight of evidence approach (i.e. precipitation excluded).

The GIS crosswalk based on all five variables indicated that California and Louisiana did not have any matching sites. For New York over 48,902,000 ha and for Oklahoma over 41,381,000 ha of matching regions were found. When areas within matching ecoregions were calculated, the values were 43,575,847 ha and 17,828,812 ha for New York and Oklahoma, respectively.

The GIS crosswalk based on the weights of evidence (precipitation not included) determined total areas of over 3,008,860 ha for California, 7,047,082 ha for Louisiana, 69,076,085 ha for New York and 20,866,423 ha for Oklahoma within matching ecoregions.

Based on the weights of evidence approach it is shown that all four US alpha-cypermethrin terrestrial field dissipation trial sites have similar ecoregions and site areas in Europe. Therefore, the results of the US terrestrial field dissipation study of alpha-cypermethrin are applicable to Europe.

I. MATERIAL AND METHODS

Site specific data from four sites of a US terrestrial field dissipation study [*CA 7.1.2.2.1/2, BASF DocID 2013/7002604*] were used in the ENASGIPS and GIS Crosswalk. The four sites were located in California, Louisiana, New York, and Oklahoma. A study summary is presented in section CA 7.1.2.2.1 Field data collected for the soils were provided at 0.15 m (6 inch) intervals. ENASGIPS topsoil data are for the 0 – 0.3 m depth. Therefore, the depth weighted average of the 0 - 0.15 m and 0.15 - 0.30 m samples were calculated. A summary of the site topsoil physical properties is provided in (Table 7.1.2.2.1-22). Full details on the site characterization can be found in the original TFD study report.

Table 7.1.2.2.1-22: Summary of the environmental conditions at the four terrestrial dissipation sites

	California	Louisiana	New York	Oklahoma
Weather				
Used NOAA Weather Station [a]	Porterville	Grand Coteau	Sodus Center	Geary
Average Temperature [ºC] study period [b]	15.6	19.1	7.9	14.9
Total Precipitation [mm] study period	106.7	1292.9	662.9	459.7
Topsoil Properties (0-0.3 m, Depth weighted average)				
Soil Series	Nord	Dundee	Oakville	Pond Creek
Texture (USDA)	Sandy loam	Silt clay loam	Sand	Sandy loam
Slope [%]	0 - 2	0 - 1	0 - 6	1 - 3
Organic matter content [%]	0.9	1.5	1.4	0.9
Soil pH	7.2	6.3	6.6	6.0

[a] Nearby NOAA weather stations were used to determine the needed climate data, because the field data did not cover a 12-month period to calculate annual averages.
[b] Study periods were 17-Jul-2012 through 26-Apr-2013 (283 days) for California, 26-Jun-2012 through 08-Apr-2013 (286 days) for Louisiana, 10-Jul-2012 through 20-Apr-2013 (284) for New York, and 27-Jun-2012 through 06-Apr-2013 (283 days) for Oklahoma. These periods represent the time from the first application through the last field sampling analyzed for alpha-cypermethrin residues.

ENASGIPS Application

ENASGIPS is a component of an OECD project to maximize the use of pesticide field dissipation studies by developing harmonized international guidance for conducting the studies and identifying comparable North American and European ecoregions [*OECD (2012) Report of the OECD Workshop on the Development of Harmonized International Guidance for Pesticide Terrestrial Field Dissipation Studies and Crosswalk of North American & European Eco-regions. Series on Pesticides. No. 68. ENV/JM/MOM(2012)11. Available at http://www.oecd.org/officialdocuments/publicdisplaydocumentpdf/?cote=env/jm/mono(2012)11&doclanguage=en. Last accessed Dec 12, 2014*]. The underlying premise of ENASGIPS is that the field dissipation behavior of a pesticide in a region depends on environmental factors, such as soils and climate. If these environmental factors are similar between regions, then field dissipation of a pesticide is also expected to be similar in those regions.

ENASGIPS consist of five individual components including:

- A tool for identifying ecoregions with similar soil and climate data
- A tool for site selection based on user defined soil, climate and crop criteria
- A tool for displaying crop density (percentage of land covered by crop) for Canada, United States and the European Union
- A tool for entering user site coordinates
- A geographic database of soil, climate and crop information

A main component of ENASGIPS is the Ecoregion Similarity Modelling (ESM). ESM's goal is to compare and identify similar ecoregions between North America and the European Union. The underlying assumption of ENASGIPS is that site specific characteristics of soil and climate play a major role in determining the behavior and fate of pesticides introduced into the environment. Principle soil factors that influence the pesticide behavior to a large extent are pH, organic carbon, and texture, although other properties such as cation exchange capacity (CEC) play a role. Climatic parameters include precipitation and temperature. A pesticide is expected to behave similarly in ecoregions that have similar soils and climate.

Depending on the properties of the pesticide of interest, not all parameters may be important for determining field dissipation and a subset of these five parameters may be used to refine the ecoregion comparison. When all five parameters are used the comparison is termed "holistic". When a subset of the parameters is used the comparison is termed "weights of evidence". With either comparison approach, ecoregions are considered similar when their weighted similarity scores are 80% or higher.

Holistic Assessment

The first step in the holistic ecoregions similarity assessment was to determine the ecoregions (henceforth referred to as root ecoregions) that overlap the four US TFD test sites. Next, for each root ecoregion the holistic ecoregions crosswalk tool was executed with a target similarity level of 80%. Eighty percent is the proposed default similarity score for use with the ENASGIPS tool as specified in the draft OECD harmonization project [*OECD (2012)*].

Weights of Evidence Assessment

The weights of evidence assessment was conducted, using the root ecoregions determined in the holistic approach. Based on the conceptual model of cypermethrins field dissipation, hypothesizing that cypermethrins remain sorbed in the topsoil compartment where biotic processes convert it to non-persistent products, the weights of evidence approach used soil texture, topsoil organic matter, pH, and temperature to determine which ecoregions in Europe matched the four root ecoregions, excluding precipitation. The target similarity level was 80%.

GIS Crosswalk

In addition to the holistic and weights of evidence ecoregion similarity assessments, ENASGIPS's Site Selection tool was used in a GIS crosswalk. Using the key parameters identified in the cypermethrins conceptual model sites in Europe were selected that adhere to specific value ranges based on the US field site characteristics. Parameters included in the weights of evidence site selection were soil texture, topsoil organic matter, pH, and temperature. A separate, holistic assessment also included precipitation (although not a major factor according to the conceptual model) to provide a complete overview of areas in Europe that are similar. Value ranges for these parameters were chosen based on values recorded at the field sites, the US Department of Agriculture Natural Resources Conservation Service (USDA NRCS) Soil Survey Geographic Database [*SSURGO: SOIL SURVEY STAFF (2013): Gridded Soil Survey Geographic (gSSURGO) Database for the Conterminous United States, United States Department of Agriculture, Natural Resources Conservation Service, available online at http://datagateway.nrcs.usda.gov/, November 2013*] and NOAA long-term annual climatic data. Table 7.1.2.2.1-23 lists the selection criteria used.

Table 7.1.2.2.1-23: Selection criteria used in the site assessment

	California		**Louisiana**		**New York**		**Oklahoma**	
Weather								
	Min	Max	Min	Max	Min	Max	Min	Max
2012-2013 Average Annual Temperature [ºC]	16.5		20.7		9.8		14.9 [a]	
Average Annual Temperature [ºC] [b]	16.1	16.9	15.0	26.4	8.8	10.9	12.5	17.3

[a] Based on the study period. NOAA does not have complete data coverage for 2012-2013 for Geary, OK

[b] Range determined by calculating the standard deviation of the annual average data for 2001-2013 and adding or subtracting one standard deviation from the 2012-2013 average.

II. RESULTS AND DISCUSSION

Ecoregion Similarity Assessment

The first step in the ecoregion similarity assessment was to determine the root ecoregions for each of the four US terrestrial field dissipation sites located in the states of California, Louisiana, New York, and Oklahoma.

As a result, field dissipation study sites were located in the "California Central Valley grasslands" ecoregion (California), in the "Mississippi Lowland forests" ecoregion (Louisiana), the "Southern Great Lakes forest" ecoregion (New York) and in the "Central and Southern mixed grasslands" ecoregion (Oklahoma). Detailed characterizations of the ecoregions are given in the study report.

Holistic Similarity

The holistic ecoregions crosswalk resulted in 14 ecoregions in Europe that have similar conditions to the root ecoregion containing the California field dissipation trial site. Similar ecoregions are located in Portugal, Spain, Southern France, Italy, Greece, Romania, and Hungary. The similarity score ranged from 81 to 100%.

The holistic ecoregions crosswalk for the Louisiana site resulted in no ecoregions in Europe that have similar conditions based on the 80% cutoff, but has 5 matching ecoregions with a 65% or greater similarity score. The similarity scores ranged from 66 to 68%.

The holistic ecoregions crosswalk for the New York site resulted in 10 ecoregions in Europe that have similar conditions. Similar ecoregions are located in France, Belgium, Netherlands, and Germany and are more representative of the coastal temperate climates. The similarity score ranged from 80 to 92%.

The holistic ecoregions crosswalk for the Oklahoma study site resulted in 7 ecoregions in Europe that have similar conditions. Similar ecoregions are located in Italy, Greece, and Romania. The similarity score ranged from 81 to 91%.

Results from the holistic similarity assessment show that matching ecoregions exist in Europe for the California, New York and Oklahoma study sites. The total area of matching ecoregions in Europe ranged from 40,710,000 ha to 158,117,000 ha. However, no matching ecoregions were found for the Louisiana study site using the 80% similarity criteria and including all five similarity parameters in the holistic assessment.

Weights of Evidence Similarity Assessment

In the weights of evidence similarity assessment soil texture, organic matter, pH, and annual average temperature were considered. These are the primary factors affecting cypermethrins field dissipation according to the conceptual model. Precipitation was excluded from the weights of evidence assessment as previously discussed.

The weights of evidence crosswalk for the California study site resulted in 10 ecoregions in Europe that are similar. Matching ecoregions are location in southern Portugal, Spain, Italy, and Greece. The similarity scores ranged from 81 to 100%.

The weights of evidence crosswalk for the Louisiana study site resulted in 4 ecoregions in Europe that are similar. Matching ecoregions are located in southern Portugal, Spain and Greece. The similarity scores ranged from 80 to 82%.

The weights of evidence crosswalk for the New York study site resulted in 13 ecoregions in Europe that are similar. Similar ecoregions are located in a wide band stretching from Northern Spain, France to Poland, Hungary and Bulgaria in the east. The similarity scores ranged from 82 to 96%.

The weights of evidence crosswalk for the Oklahoma study site resulted in 11 ecoregions in Europe that are similar. Similar ecoregion are located in the coastal Spain and France, most of Italy and Greece. The similarity scores ranged from 83 to 94%.

Results from the weights of evidence similarity assessment show that for each of the four US TFD study sites, 4 to 13 different similar ecoregions exist in Europe.

GIS Crosswalk

Using the site selection tool a GIS crosswalk was conducted for the four terrestrial field dissipation sites using the holistic approach (all variables) and the weights of evidence approach (i.e. all variables except precipitation).

Results indicate that the total area of matching land is very similar when the holistic and weights of evidence approaches are compared. The GIS crosswalk indicated that California and Louisiana did not have any matching sites using all variables. For New York over 48,902,000 ha and for Oklahoma over 41,381,000 ha of matching regions were found. When areas within matching ecoregions were calculated, the values were to 43,575,847 ha and 17,828,812 ha for New York and Oklahoma, respectively.

The GIS crosswalk based on the weights of evidence determined total areas of 3,008,860 ha for California, 7,047,082 ha for Louisiana, 69,076,085 ha for New York and 20,866,423 ha for Oklahoma within areas in matching ecoregions based on the weights of evidence approach.

Based on the holistic approach, the total area of matching areas within matching ecoregions was 89% for the New York site and 43% for the Oklahoma study sites. No matching areas were found for the California and Louisiana trial sites. Using the weights of evidence approach, 43% to 86% of the areas with matching soil and climate criteria fall within matching ecoregions for all four US terrestrial field dissipation sites.

III. CONCLUSIONS

The objective of the project was to conduct an ecoregion similarity assessment and GIS Crosswalk for four US field dissipation test sites and determine which locations in Europe, if any, have similar conditions. All work was conducted using the Organisation for Economic Co-operation and Development (OECD) Europe – North America Soil Geographic Information for Pesticide Studies (ENASGIPS) application. Ecoregion similarity and GIS crosswalks were conducted in support of (re)registration of alpha-cypermethrin in Europe.

Results from the holistic similarity assessment show the matching ecoregions exceeding the 80% similarity level exist in Europe for the California, New York, and Oklahoma study sites. No matching ecoregions were found for the Louisiana study site using the 80% similarity criteria. In the holistic similarity assessment topsoil texture, topsoil organic matter, topsoil pH, annual average temperature, and average annual total precipitation were considered.

Results from the weights of evidence similarity assessment show that for each of the four US study sites, 4 to 13 similar ecoregions exceeding the 80% similarity level exist in Europe. In the weights of evidence similarity assessment topsoil texture, topsoil organic matter, topsoil pH, and annual average temperature were considered. Precipitation was not included as it was considered unimportant for explaining field dissipation behavior of strongly sorbed cypermethrins such as alpha-cypermethrin, especially since field dissipation test sites are irrigated to supplement natural precipitation.

The GIS crosswalk indicated that California and Louisiana did not have any matching sites using all five variables in a holistic assessment. For New York 43,575,847 ha and for Oklahoma over 17,828,812 ha of matching areas were found within the matching ecoregions.

The GIS crosswalk based on the weights of evidence determined total areas of 3,008,860 ha for California, 7,047,082 ha for Louisiana, 69,076,085 ha for New York, and 20,866,423 ha for Oklahoma within matching ecoregions based on the weights of evidence approach.

Based on the weights of evidence approach it is shown that all four US alpha-cypermethrin terrestrial field dissipation trial sites have similar ecoregions and site areas in Europe. Therefore, results for the US terrestrial field dissipation study of alpha-cypermethrin are applicable to Europe.

Guidelines:	NAFTA Guidance Document for Conducting Terrestrial Field Dissipation Studies Regulatory Directive DIR2006-01 (March 2006), EPA 835.6100, EEC 1607/VI/97 rev. 2 10.06.1999, SANCO/3029/99 rev. 4 (11 July 2000), SETAC Procedures for assessing the environmental fate and ecotoxicity for pesticides (March 1995), EFSA Guidance to obtain DegT50 values in soil (2010)
GLP:	yes (certified by Staatliches Gewerbeaufsichtsamt, Hildesheim, Germany)

The amendment to the report contains corrections of typos and calculation errors.

Executive Summary

The dissipation of alpha-cypermethrin (BAS 310 I) under field conditions was investigated at six sites in Europe representative of Northern and Southern EU conditions. One trial each was performed in Northern Germany, Southern Germany, United Kingdom, Bulgaria, Spain, and in Southern France. All sites represent typical regions of agricultural practice representative for growing crops including wheat. The trial sites consisted of an untreated and a treated plot, the latter being subdivided into 3 subplots that were assigned for replicates.

The product BAS 310 55 I, formulated as a micro-emulsion (ME), was broadcast applied to bare soil in a single application at a nominal rate of 60 g a.s. ha^{-1} using a target water volume of 400 L ha^{-1}. Applications were conducted between early June and late July 2012 using a calibrated boom sprayer. The actual application rates for each trial determined by quantifying the amount of spray discharged ranged from 56 to 64 g a.s. ha^{-1}, with an average of 61 g a.s. ha^{-1}. Results from spray broth analysis for the individual trial sites revealed concentrations between 89 and 105% of the nominal value with an average of 98% across all sites. Dose verification conducted via application verification samples yielded recovery values for the individual sites ranging from 88 to 130% of the target rate and an average recovery of 109% across all sites.

Immediately after application of the test item, the plots were covered with a layer of sand of at least 3 – 5 mm depth to protect the applied product from surface processes like photolysis or volatilization, and to exclude any potential impact on the degradation of the test item caused by any of these processes. Thickness and homogeneity of the sand cover were controlled and maintained at least until the field received a total precipitation (rain and irrigation) of ≥ 10 mm. Since the sand cover remained intact until then, it was not necessary to renew it. Within the time period of up to 28 days after application, the individual plots received a total precipitation (rain and irrigation) of ≥ 10 mm (Northern Germany: 25.4 mm after 9 days, Southern Germany: 16.8 mm after 3 days, United Kingdom: 12.8 mm after 28 days, Bulgaria: 48.4 mm within 2 days, Spain: 12.7 mm within 14 days and France: 15.8 mm after 1 day).

No tillage or fertilization was performed during the course of the study and no crops were grown throughout any of the trials. The plots were kept generally free of vegetation (< 10% of weeds) via the application of glyphosate.

Rainfall was supplemented with irrigation at sites in Northern Germany (130.7 mm), Southern Germany (57.9 mm), United Kingdom (93.3 mm), Bulgaria (408.5 mm), Spain (195.1 mm) and Southern France (61.5 mm) the total water input was at least 107% of the historical average rainfall during the study period at the trial sites.

Soil residue specimens were taken at intervals up to 368 days after treatment (DAT) and down to a maximum soil depth of 50 cm. Soil cores below 10 cm depth (excepting usually the doubles) were cut into 10 cm segments. Soil segments of the same depth and subplot from a defined sampling, plot, event, and site were pooled and homogenized. A representative sub-sample of each depth was taken for residue analysis. All soil specimens were generally stored at about -18°C within a maximum of 6 hours after end of sampling, except the untreated soil specimen of one sampling from trial Germany North (L120555) and France South (L120560) which were placed into freezer storage at generally -18°C within 7 hours and 8.5 hours after end of sampling, and remained frozen until analysis.

In order to demonstrate stability of the residues in soil during storage and shipment, shipment verification specimens were prepared at selected sampling occasions by fortifying untreated soil from the field sites with a standard solution of alpha-cypermethrin. These specimens were stored and shipped under the same conditions as the actual residue specimens. Analysis of the shipping verification specimens on alpha-cypermethrin yielded average recovery values of 90-131% across all sites confirming residue stability during all storage and shipment procedures.

Soil specimens, as well as application monitors (Petri dishes) and shipping verification specimens were analyzed for cypermethrin isomers cis-1, cis-2, trans-3, and trans-4, and its metabolites 3-PBA and DCVA isomers cis and trans to the BASF analytical method R0034/01.

The analytical method of cypermethrin isomers cis-1, cis-2, trans-3, and trans-4 involved extraction of the soil with 0.1% formic acid in acetonitrile, evaporation to dryness, and reconstitution in 0.1% formic acid in acetonitrile/water (1:1, v/v). The analytical method of 3-PBA and DCVA isomers cis and trans involved two extractions of the soil with acetonitrile/water (70:30, v/v), evaporation to dryness of an aliquot of the extracts and reconstitution in 0.1% formic acid in methanol/water (20:80, v/v).

The final determination of the analytes was performed by HPLC-MS/MS with a limit of quantification (LOQ) of 0.001 mg kg^{-1} for each analyte. Field soil specimens from the treated plot were analyzed down to a depth until at least two consecutive soil segments were free of quantifiable residues (< LOQ). Analysis was performed until a maximum of 368 DAT.

No residues above 30% of the LOQ of any analyte were detected in any of the untreated control samples proving that there were no interferences of the untreated soil material with the analytical procedure used. Procedural recovery experiments performed with untreated soils spiked with the analytes at concentrations of 0.001, 0.01, and 0.5 mg kg^{-1} yielded overall mean recovery rates of 92 and 98% for the individual analytes, confirming the validity of the analytical method used in this study.

Residue values of cypermethrin isomer cis-2 and of the sum of cypermethrin isomers cis-1 and cis-2 in mg kg^{-1} dry were summed up for all depths between 0 and 50 cm analyzed and converted to µg kg^{-1} for an improved readability.

Alpha-cypermethrin degraded under field conditions in soil at all six European field sites. The total amount of the sum of cypermethrin isomers cis-1 and cis-2 residues detected in the soil profiles decreased from an average of 39 µg kg^{-1} at 0 DAT to an average of 8 µg kg^{-1} (range: 0 – 20 µg kg^{-1}) at 60 DAT. Until the end of the study at about 360 DAT, residues decreased further to concentrations equal or below LOQ at four of the six trials, which equals to about 0 µg kg^{-1}. The two trials left with residues above LOQ showed mean rates of 5 µg kg^{-1} (range: 3 – 6 µg kg^{-1}) at the end of the study. DT_{50} values are subject of a separate study and modeling report

Altogether, it can be concluded that cypermethrin isomer did not show any significant tendency to move into deeper soil layers indicating low potential for cypermethrin isomer residues to leach to groundwater in this study.

Residues of the metabolites 3-PBA and DCVA (cis isomer only) above LOQ were only found in the top 0 – 10 cm three out of six field sites (Bulgaria, Spain, and France). Residues above LOQ were exclusively found at trial sites Bulgaria and Spain.

Metabolite DCVA isomer cis was detected in small amounts reaching a maximum of 3.3 µg kg^{-1} (Bulgaria; 14 DAT) and 2.7 µg kg^{-1} (Spain; 60 DAT) on average for the three subplots. Thereafter, residues declined and were no longer detected in amounts > LOQ after 132 days at the latest.

Metabolite 3-PBA was detected above LOQ in small amounts reaching maximum amounts of 2.5 µg kg^{-1} (Bulgaria; 30 DAT) and 3.0 µg kg^{-1} (Spain; 60 DAT) on average for the three subplots. Thereafter, residues declined and were no longer detected in amounts > LOQ after 85 days at the latest.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test item (formulation):	BAS 310 55 I
Active substance (a.s.):	Alpha-cypermethrin (BAS 310 I, Reg. No. 4078193)
Chemical name (IUPAC):	Racemate of (S)-α-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-α-cyano-3-phenoxybenzyl (1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Molar mass:	416.3 g mol^{-1}
Batch No.:	101209 /(containing 49.2 g alpha-cypermethrin L^{-1})
Type of formulation:	ME

2. Test sites

The dissipation of alpha-cypermethrin under field conditions was investigated at six sites in Europe representative of Northern and Southern EU conditions. One trial each was performed in Northern Germany, Southern Germany, United Kingdom, Bulgaria, Spain, and in Southern France. The visual homogeneity of the upper soil layer was verified at the beginning of each field phase. The site characteristics are presented in Table 7.1.2.2.1-24 to Table 7.1.2.2.1-26. Soil parameters were determined at Eurofins Institut Jäger GmbH (Tübingen, Germany) from soil samples taken before application from the boundaries of the future treated subplots (SP) following segmentation according to the visually identified soil horizons.

The selected field sites represented typical regions of agricultural practice with soils representative for growing wheat that had been under cultivation for several years. The sites were generally flat without any significant slope except the site in Spain, which was flat with a slope of approximately 2.6%. The field sites have been without any pasture, trees, or vine since 2009. Before commencement of the first sampling, the soil at each trial site was prepared as fine and firm seedbed and rolled if considered necessary, but then was left fallow.

No product containing the active substance of the test item had been used on the test plots in the last three years.

B. STUDY DESIGN

1. Experimental treatments

The trial area at each site was divided into two plots, one untreated control plot (U1: size: 30 – 90 m^2) and one treated plot (treatment 2: size: 288 – 414 m^2). The treated plot consisted of three equal sized subplots SP1, SP2, and SP3 that were assigned for replicates.

The product, formulated as microemulsion (ME), was broadcast applied to bare soil in a single application at a nominal rate of 60 g a.s. ha^{-1} using a target water volume of 400 L ha^{-1}. Applications were conducted between early June and late July 2012 using calibrated boom sprayers. Treated subplots were three-fold replicated with subplot size ranging from 96 to 138 m^2. For each treated replicate, a separate spray mixture was prepared and the test item was applied to each subplot individually. Each spray mixture was visually checked for homogeneity and small aliquots of the spray mixture were taken before and after application of each individual subplot for later analysis.

The actual application rates determined by quantifying the amount of spray discharged ranged from 59 to 63 g a.s. ha^{-1} averaged over the three replicates of each treated plot. In addition, the dose was verified by means of sampling Petri dishes filled with fine untreated soil from the trial site (approximately 50 g per dish, sieved to 3.2 – 1 mm). The Petri dishes with an inner diameter of 10.8 cm were placed on the treated plot (ten in each subplot) before application. On completion of the application, the Petri dishes were closed with a lid, sealed with adhesive tape, stored chilled after collection, and placed in freezer storage within 5 hours after application. Further details of application are presented in Table 7.1.2.2.1-27 below.

Table 7.1.2.2.1-27: Application rates of plots treated with BAS 310 55 I (ME)

* Determined by calculation of the applied spray volume on the plot based on analysed a.s. density and content
** Determined by means of 10 Petri dishes filled with soil

Immediately after application of the test item and before subsequent residue soil core sampling, the control plot and the treated replicates were covered with a thin layer of sand to protect the applied product from surface processes like photolysis or volatilization, and to exclude any potential impact on the degradation of the test item caused by any of these processes. The application of sand was conducted manually or using spades until complete coverage of the soil surface was reached. Fine or medium grained sand was used. The thickness of the sand layer necessary for complete coverage of the soil was at least around 3 – 5 mm (range around: 3 - 15 mm).

Thickness and homogeneity of the sand cover were controlled and maintained at least until the field received a total precipitation (rain and irrigation) of ≥ 10 mm. Since the sand cover remained intact until then, it was not necessary to renew it. Within the time period of up to 28 days after application, the individual fields received a total precipitation (rain and irrigation) of ≥ 10 mm (Germany (North): 16.2 mm within 9 days, Germany (South): 16.8 mm within 3 days, United Kingdom: 12.8 mm within 28 days, Bulgaria: 48.4 mm within 2 days, Spain: 12.7 mm within 14 days, and France: 15.8 mm after 1 day).

No tillage or fertilization was performed during the course of the study from first to last sampling and no crops were grown throughout any of the trials. The plots were kept generally free of weeds via the application of glyphosate.

Rainfall was supplemented with irrigation at sites in Germany (North; 130.7 mm), Germany (South; 57.9 mm), United Kingdom (93.3 mm), Bulgaria (408.0 mm), Spain (170.4 mm), and France (South; 49.6 mm).

Actual weather data are based on records of appropriate weather stations located on-site. Monthly summary results on temperature, precipitation and irrigation are presented in Table 7.1.2.2.1-28.

Weather data refer to time period from start of trial (day of application) until end of trial (day of last sampling).

Historical (long-term) weather data on precipitation and average air temperature from at least 10 years (exception trial Bulgaria (L120558): 9 years) were taken from official weather stations located nearby (5.3 - 30 km distance to trial site). The historical and actual data (mean air temperature and precipitation), each averaged over the complete duration of the individual trials are presented in Table 7.1.2.2.1-29.

The actual air temperature recorded at the field sites during the study period was similar to the historic values, except for significantly lower than average temperatures in Spain. Whereas the sites in Spain and France (South) received more rain during the study period compared to the historical values, rainfall was less than the historic values in Germany (North) and Bulgaria. Due to additional irrigation, the total water input at the trial sites during the study was at least 107% of the historical average rainfall, which is considered sufficient to allow the cultivation of crops like wheat.

Table 7.1.2.2.1-29: Summary of historical and actual weather data at field trial sites corresponding to the entire trial duration (1 year)

Trial Country	T_{mean} Air [°C] (average over trial period)		Precipitation [mm] (sum over trial period)		Irrigation [mm]	Sum of actual precipitation and irrigation [mm]	% of historic precipitation

* At least over nine years
**Calculated for the respective parts of the months from day of application until day of last sampling

2. Sampling

Replicate soil residue specimens (8 cores per treated subplot and 10 or 15 per control plot (exception trial Southern Germany (L120556): 15 or 8 cores per control plot) were taken at intervals up to 368 DAT and down to a maximum soil depth of 50 cm. At day 0, immediately after application, collection of Petri dishes, and sand cover, the treated subplots were sampled down to 10 cm only. From 3 DAT the sampling depth was 50 cm. The detailed sampling intervals are presented in Table 7.1.2.2.1-30.

Table 7.1.2.2.1-30: Summary of sampling intervals of residue soil samples at each field trial site

Trial	Country	Sampling intervals [days after treatment]
S12-01863-01 L120555	Germany (North)	-0, 0, 4, 8, 13, 32, 57, 91, 138, 181, 258, 309, 368
S12-01863-02 L120556	Germany (South)	-1, 0, 3, 8, 15, 30, 66, 94, 141, 176, 239/ 240, 294, 367

S12-01863-05 L120559	Spain	-3/6, 0, 4, 7, 14, 29, 61, 85, 132, 180, 243, 292, 355
S12-01863-06 L120560	France (South)	0, 4, 8, 14, 27, 56, 97, 140, 175, 238, 306, 368

Untreated specimens were sampled from the control plot on two occasions, between zero and three days before application down to a depth of 50 cm, and after about one year to a depth of 10 cm with the exception of trial Spain (L120559), where the double samples of the first sampling of untreated specimen were taken 9 days after the corresponding main samples (6 DAT). The specimens were taken within the dedicated subsubplot of the untreated plot each time and pooled according to soil depth. The 15 cores collected at the first sampling interval were taken using a soil corer equipped with a plastic or acetate tube liner of 4.3 to 5.0 cm diameter. The cores taken after about one year were collected with a metal tube or a metal tube in tube system of minimum 7.9 and maximum 10.0 cm diameter.

Treated soil specimens were taken at 8 different spots within the randomly assigned subsubplot from each of the three treated subplots SP1 to SP3 and pooled according to subplot, timing, and depth. All soil specimens from 0-10 cm depth collected from the treated subplots were taken separately using a metal tube or a metal tube in tube system of minimum 7.9 and maximum 10.0 cm diameter which left a hole contained by a metal tube. Alternatively, samples were taken by pressing the metal tube described above into the ground and collecting the soil with a spoon or similar device. Soil specimens deeper than 10 cm were collected through the centre of the excavation hole contained by the metal tube, using a soil corer fitted with a plastic or acetate tube liner of diameter 4.3 to 5.0 cm. Sampling of the 10 – 50 cm cores was conducted in one piece.

In addition to the main sampling described above, a second complete sampling (double sampling) was carried out for back-up purposes. The double samples of the 10 - 50 cm layers were not sectioned into 10 cm segments but directly put into the freezers at the field test sites or at the analytical test site. Deviating from this procedure, one double sample from trial France (L120560) was cut into segments of 0 - 30 cm, 30 - 40 cm, and 40 - 50 cm, as well as double samples from trial United Kingdom (L120557) and Bulgaria (L120558), which were sectioned into 10 cm segments.

All soil specimens intended for residue analysis were stored at about -18°C within a maximum of 8.5 hours after sampling and remained frozen through storage, shipping, and processing until final analysis. Sample processing was conducted in frozen state in a mill together with dry ice.

Shipment verification specimens were prepared to demonstrate stability of the residues in soil during storage and through any shipping processes. The samples were prepared at three occasions by fortification of soil with 0.15 mg kg^{-1} alpha-cypermethrin and were subsequently handled in the same manner as the actual residue samples. The analytical results demonstrated no significant losses from the shipping verification samples. The average recovery of the sum of cypermethrin cis isomers was 100% (range: 90 - 131%) across all trials.

3. Analytical procedure

Field soil specimens, as well as Spray broth, Petri dish, and shipping verification specimens were analyzed for cypermethrin isomers cis-1, cis-2, trans-3, and trans-4, and its metabolites 3-PBA and DCVA isomers cis and trans according to the analytical method R0034/01 [*DIAMADUROS, K., DOWNS, C., MALINSKY, D. (2013) Method for the Quantitation of the Diastereomeric Forms of BAS 311 I (Reg. 127266) and its Metabolites 3-Phenoxybenzoic Acid (Reg. No. 130213) and DCVA (Cis and Trans Isomers, Reg. No. 180011) in soil by LC-MS/MS*] provided by BASF.

The analytical method of cypermethrin isomers cis-1, cis-2, trans-3, and trans-4 involved extraction of the soil with 0.1% formic acid in acetonitrile, evaporation to dryness and reconstitution in 0.1% formic acid in acetonitrile/water (1:1, v/v) and final determination of the analytes by HPLC-MS/MS.

The analytical method of 3-PBA and DCVA isomers cis and trans involved two extraction of the soil with acetonitrile/water (70:30, v/v), evaporation to dryness of an aliquot of the extracts and reconstitution in 0.1% formic acid in methanol/water (20:80, v/v) and final determination of the analytes by HPLC-MS/MS.

The limit of quantification (LOQ) was 0.001 mg kg^{-1} for each individual analyte related to wet soil. The limit of detection (LOD) was set at 0.0003 mg kg^{-1} (30% of LOQ).

Analysis of field soil specimens originating from the treated plots was conducted down to a depth until at least two consecutive soil segments were free of quantifiable residues (< LOQ of 0.001 mg kg^{-1}). Analysis was performed up to a maximum of 368 DAT.

The methods used were validated during the current study according to guideline SANCO/3029/99 rev. 4. In addition, untreated control and fortified samples were analyzed within each analytical sample set.

4. Storage stability experiments

Storage stability of alpha-cypermethrin and its metabolites 3-PBA and DCVA (cis and trans isomers) in frozen soil was investigated in a separate study *[CA 7.1.2.2.1/5, BASF DocID 2014/1000723]* with soils originating from the individual trial sites of the present terrestrial field dissipation study.

5. Calculation of degradation times

No calculation of degradation times is provided in the study report. A detailed kinetic evaluation of the degradation behavior of alpha-cypermethrin and its metabolites in the six European field soils is presented in a separate modeling report [*CA 7.1.2.2.1/5, STUDENROTH S., PAPE L., 2014, BASF DocID 2014/1159508*].

II. RESULTS AND DISCUSSION

1. Spray broth concentration and application verification

Spray mixtures as well as application verification samples (Petri dishes) were analyzed for cypermethrin isomers cis-1, cis-2, trans-3, and trans-4. Due to the low detections and the resulting negligible influence, cypermethrin trans isomers are not summarized below, but shown in the analytical phase report.

Spray broth homogeneity was confirmed by visual check for all trials. Spray mixtures were sampled before and after application of each subplot. Analyzed concentrations of the sum of cypermethrin cis isomers averaged for the individual trial sites were in the range of 0.134 to 0.157 g L^{-1} corresponding to 89 - 105% of the target concentration of 0.150 g L^{-1}. The analytical results were not corrected for procedural recoveries and confirm the integrity of the test item used in the trials.

Application verification was conducted by means of petri dishes filled with fine untreated soil from the trial site. Residue levels of the sum of cypermethrin isomers cis-1 and cis-2 achieved on extraction and analysis of the application monitors were converted into residue rates (in g a.s. ha^{-1}) taking into account the area of the Petri dishes (91.6 cm^2). As a result, the obtained rates for the individual trials ranged from 53 to 78 g a.s. ha^{-1} representing 88 - 130% of the target application rate. The applied amount determined via the application monitors in these trials is in agreement with the nominal value of 60 g ha^{-1}, and the results from spray broth analysis.

2. Residues in field soil samples

Untreated soil specimens (control samples) of the respective soil depths from each trial were analyzed for residues of cypermethrin isomers cis-1, cis-2, trans-3, and trans-4 and its metabolites 3-PBA and DCVA isomers cis and trans. No residues above LOD of any analyte were detected in any of the control samples proving that there were no interferences of the untreated soil material with the analytical procedures used. Procedural recovery experiments performed with untreated field soil specimens spiked with cypermethrin isomers cis-1, cis-2, trans-3, and trans-4, and its metabolites 3-PBA and DCVA isomers cis and trans reference items at concentration levels of 0.001, 0.01, and 0.5 mg kg^{-1} (related to wet soil - the highest spiking level was used only for parent compound fortifications), yielded mean recovery rates for the individual analytes between 91 and 98%, confirming the validity of the analytical method used in this study. Detailed results are summarized in Table 7.1.2.2.1-31.

Table 7.1.2.2.1-31: Method procedural recoveries

Analyte	Fortification level [mg kg^{-1}]	n	Mean recovery ± RSD [%]
Cypermethrin isomer cis-1	0.001	74	98 ± 10
	0.01	86	97 ± 9
	0.5	77	98 ± 5

	0.01	59	94 ± 13
	All fortification levels	**129**	**94 ± 14**
Sum of DCVA isomers [a]	0.002	70	92 ± 13
	0.02	59	93 ± 13
	All fortification levels	**129**	**92 ± 13**
3-PBA	0.001	70	92 ± 14
	0.01	59	92 ± 16
	All fortification levels	**129**	**92 ± 15**

RSD = Relative standard deviation [%]
Remark: Differences between fortification levels are due to Isomer ratio in reference items. The calculation of the recovery is related to the nominal fortification level.
[a] All Isomers are included, each individual by 50%

These data prove that the analytical method applied was able to accurately determine residues of cypermethrin isomers cis-1, cis-2, trans-3, and trans-4, and its metabolites 3-PBA and DCVA isomers cis and trans in soil samples down to a concentration of 0.001 mg kg^{-1} for each analyte.

Field soil specimens from the treated plots were analyzed down to a depth until at least two consecutive soil segments were free of quantifiable residues (< LOQ of 0.001 mg kg^{-1}, maximum depth of 50 cm). If samples were analyzed in duplicate, the individual numbers were averaged to produce a mean for the respective soil sample. If one of the values was below the LOQ, it was averaged as half of LOQ, here however related to dry soil. In general, decision weather residues are below or above LOQ are taken on wet soil basis. Individual concentrations of isomers are then converted to dry soil. In case isomers are summarized (cis-1 and cis-2), wet soil related values were added. If one value is below LOQ (selection on wet soil basis), but above LOD, a value of half of the LOQ (0.0005 mg kg^{-1} wet weight related) is converted to dry soil and is taken for calculation; values below LOD are taken as 0.0 mg kg^{-1}. This means, that LOQ for sum of two isomers (cis-1 and cis-2, as well as for DCVA cis and trans) is 0.002 mg kg^{-1}, and LOD for sum of two isomers is 0.0006 mg kg^{-1}.

All residue values presented are related to the dry weight of the soil and were not corrected for procedural recoveries. The obtained residue rates in mg kg^{-1} were summed up for all depths between 0 and 50 cm analyzed.

The analytical average results of cypermethrin isomer cis-2 (alpha-cypermethrin) and the sum of cypermethrin isomers cis-1 and cis-2 were converted from mg kg^{-1} to µg kg^{-1} for an improved readability and are summarized in Table 7.1.2.2.1-32 and Table 7.1.2.2.1-33. Trans isomers are not added to the sum of cis isomers due to their limited detections and as a result, of their negligible influence.

As is evident from the analytical data, cypermethrin isomers degraded at all six European field sites. The total amount of the sum of cypermethrin isomers cis-1 and cis-2 residues detected in the soil profiles decreased from an average of 39 µg kg^{-1} at 0 DAT to an average of 8 µg kg^{-1} (range: 0 – 20 µg kg^{-1}) at 60 DAT. The residues decreased to an average of 2 µg kg^{-1} at the end of the study, ranging from 0 to 6 µg kg^{-1}.

Considering the distribution of cypermethrin isomer residues in the soil profiles, the main proportion was always measured in the top 0 - 10 cm soil layer and only small amounts of the compound were detected in the 10 – 20 cm layer (≤ 7 µg kg^{-1}). No residues above the LOQ were detected below 20 cm in any sample.

Altogether, it can be concluded that cypermethrin isomers do not show any significant tendency to move into deeper soil layers indicating low potential for cypermethrin isomer residues to leach to groundwater.

Residues of the metabolites 3-PBA and DCVA (cis isomer only) were only found in three out of six field sites: L120558 (Bulgaria), L120559 (Spain), and L120560 (France). Residues above LOQ were exclusively found between 14 and 85 DAT in the top 0 - 10 cm soil layer at L120558 and L120559.

The analytical results of the metabolites cis-DCVA and 3-PBA in field trials L120558 and L120559 are shown in Table 7.1.2.2.1-34.

Table 7.1.2.2.1-34: Total residues of cis-DCVA and 3-PBA under field conditions in soil calculated to µg kg^{-1} and summed up for all depths analyzed (trials L120558, L120559, L120560)

3. Shipment verification specimens

Shipping verification specimens spiked with alpha-cypermethrin were analyzed to check the stability of the residues in soil during storage at the test site and during any shipping processes. Concentrations of alpha-cypermethrin were not corrected for procedural recoveries.

The analytical results demonstrated no significant losses from the shipping verification samples. The average amount of the sum of alpha-cypermethrin cis isomers from the spiked shipping verification samples was 100% (range: 90 - 131%) across all trials. It was concluded that alpha-cypermethrin was stable in all soils under the storage and shipping conditions used.

4. Time of storage

The maximum period any soil sample from the present field soil dissipation study was stored from the time of sampling to extraction was 727 days for the cypermethrin isomers and ~~836~~ 708 days for the metabolites. Petri dish specimens were stored for up to 611 days after application. The maximum storage period of the spray broth samples was 355 days. Shipment verification specimens were stored for a maximum of 611 days between spiking and extraction.

III. CONCLUSION

Alpha-Cypermethrin degraded under field conditions in soil at all six European field sites. Instantly after application, cis-1 isomer could be additionally detected at 0 DAT at low rates, [redacted] The total amount of the sum of cypermethrin isomers cis-1 and cis-2 residues detected in the soil profiles decreased from an average of 39 µg kg^{-1} (range: 12 – 54 µg kg^{-1}) at 0 DAT to an average of 8 µg kg^{-1} (range: 0 – 20 µg kg^{-1}) after 60 days. Until the end of the study at about 360 DAT, residues decreased further to concentrations equal or below LOQ at four of the six trials, which equals to about 0 µg kg^{-1}. The two trials left with residues above LOQ showed mean rates of 5 µg kg^{-1} (range: 3 – 6 µg kg^{-1}) at the end of the study.

DT_{50} values either for alpha-cypermethrin and sum of both cis isomers and were subject of separate modeling reports.

Amounts of trans-3 and trans-4 isomers occurred only in two of the six trials rarely at very low amounts.

Cypermethrin isomer residues were exclusively detected in the upper 20 cm of the soils. No residues above the LOQ were detected below 20 cm in any sample. Altogether, it can be concluded that cypermethrin isomer does not show any significant tendency to move into deeper soil layers indicating very low potential for cypermethrin isomer residues to leach to groundwater.

Residues of the metabolites 3-PBA and DCVA (cis isomer only) above LOQ were only found in three out of six field sites (Bulgaria, Spain, and France). Residues above LOQ were exclusively found at trial sites Bulgaria and Spain.

Metabolite DCVA isomer cis was detected in small amounts reaching maximum amounts of 3.3 µg kg^{-1} (Bulgaria; 14 DAT) and 2.7 µg kg^{-1} (Spain; 60 DAT) on average for the three subplots. Thereafter, residues declined again and were no longer detected in amounts > LOQ after 132 days at the latest.

Metabolite 3-PBA was detected above LOQ in small amounts reaching maximum amounts of 2.5 µg kg^{-1} (Bulgaria; 30 DAT) and 3.0 µg kg^{-1} (Spain; 60 DAT) on average for the three subplots. Thereafter, residues declined again and were no longer detected in amounts > LOQ after 85 days at the latest.

Metabolites DCVA isomer cis and 3-PBA were exclusively found in the top 0 - 10 cm soil layer of the three field sites. No residues above the LOQ were observed in deeper soil layers in any sample at any site.

Calculation of maximum occurrences of DCVA and 3-PBA from the EU field dissipation study

The metabolites DCVA and 3-PBA occurred in relevant amounts in the EU field dissipation study with alpha-cypermethrin [*CA 7.1.2.2.1/4, BASF DocID 2014/1161559*]. In the following, the derivation of the maximum occurrences of the metabolites in the EU field dissipation study is described.

For the EU study, the residue data of the metabolites reported in µg kg^{-1} were converted into µg p.e. kg^{-1}, considering a molar correction factor of 0.502 for DCVA and 0.514 for 3-PBA. For alpha-cypermethrin, the sum of cis-1 and cis-2 isomer and for DCVA the cis isomer was considered. The respective trans isomers were not included due to their low detection and therefore negligible influence.

Alpha-cypermethrin was applied at one application. Maximum occurrences were calculated for the trials L120558 (Bulgaria) and L120559 (Spain), considering the maximum amount of metabolite residues (mean of three plots) after application and the initial amount of parent residues (mean of three plots). The results are summarized in Table 7.1.2.2.1-35.

Table 7.1.2.2.1-35: Maximum occurrence of alpha-cypermethrin metabolites in EU field dissipation study

Metabolite	Trial	Maximum amount of metabolite		Initial amount of parent	Maximum occurrence
		[µg kg^{-1}] [a]	[µg p.e. kg^{-1}] [b]	[µg kg^{-1}] [a]	[%]

Report:	CA 7.1.2.2.1/6 Studenroth S., Pape L., 2014b Kinetic evaluation of a field dissipation study with BAS 310 I – alpha-cypermethrin conducted in 2012 and 2013: Determination of modeling endpoints according to FOCUS 2014/1159508
Guidelines:	FOCUS Degradation Kinetics (2006) Sanco/10058/2005 version 2.0 (November 2011) EFSA Guidance to obtain DegT50 values in soil (2010)
GLP:	no

Executive Summary

The dissipation behavior of the insecticide BAS 310 I – alpha-cypermethrin in soil has been investigated in a field dissipation study including six field trials located in Germany (two trials), United Kingdom, Spain, Bulgaria and France [*CA 7.1.2.2.1/4, BASF DocID 2014/1161559*]. The purpose of this evaluation was to analyze the degradation kinetics of alpha-cypermethrin and its metabolites DCVA and 3-PBA observed in the six soils according to the current guidance of the FOCUS workgroup on degradation kinetics in order to derive normalized modeling endpoints.

The field trials were situated in different regions of Europe (Germany, United Kingdom, Bulgaria, Spain and France), considering a range of different soils and climatic conditions.

As the study design was tailored to exclude surface processes, kinetic evaluation was performed according to FOCUS kinetics as recommended by *EFSA (2014)*.

Prior to kinetic evaluation, sampling intervals of the field studies were normalized to reference conditions (20°C, pF2) by time-step normalization. The kinetic evaluation was performed on the normalized dataset. Modeling endpoints were derived based on a visual and statistical assessment. Kinetic evaluation of the time-step normalized dataset (20°C, pF2) resulted in normalized field half-lives ($DegT_{50}$) for alpha-cypermethrin between 11.7 and 114.1 days, for DCVA between 16.0 and 32.4 days and for 3-PBA between 17.1 and 35.8 days.

I. MATERIAL AND METHODS

The kinetic evaluation was conducted for six field trials with alpha-cypermethrin from the data of one field dissipation study, which can be found in *CA 7.1.2.2.1/4* [*BASF DocID 2014/1161559*]. The trials were situated in different regions of Europe (Germany (DE1 and DE2), United Kingdom (UK), Bulgaria (BG), Spain (ES) and France (FR)) considering a range of different soils and climatic conditions. Detailed soil characteristics in each trial are reported in the cited study.

Alpha-cypermethrin was applied in June 2012 in the formulation BAS 310 55 I (ME) to three replicate plots per trial to bare soil at an intended application rate of 60 g a.s. ha^{-1} using a calibrated boom sprayer. Immediately after application and before subsequent soil sampling all plots were covered with a thin layer (at least 3-5 mm) of sand and maintained at least until the field received a total precipitation (rain and irrigation) of ≥10 mm to protect the applied product from surface processes like photolysis or volatilization, and to exclude any potential impact on the degradation of the test item caused by any of these processes.

The study duration was up to 368 days after application. Soil samples were taken at 12 sampling dates after application. Replicate soil specimens from the treated subplots were taken down to a maximum soil depth of 50 cm.

The samples were extracted with 0.1% formic acid in acetonitrile and extracts were analyzed for alpha-cypermethrin isomers (cis-1, cis-2, trans-3 and trans-4) by means of HPLC-MS/MS. For analysis of the metabolites DVCA (CIS and TRANS isomers) and 3-PBA the soil was extracted two times with acetonitrile/water (70:30, v/v) and extracts were analyzed by means of HPLC-MS/MS. For each analyte the limit of quantification (LOQ) was 0.001 mg kg^{-1} and the limit of detection (LOD) was set to 0.0003 mg kg^{-1}.

Alpha-cypermethrin residues were almost exclusively found in the top 0-10 cm soil layer, with only small amounts of the compound sporadically detected in the 10-20 cm layer (≤0.0054 mg kg^{-1}). No residues above the LOQ were detected below 20 cm in any sample.

The metabolites DCVA and 3-PBA were detected in the top 0-20 cm soil layer at three sites (Bulgaria, Spain and France) whereby residues above LOQ were only found in the top 0-10 cm soil layer at the sites of Bulgaria and Spain.

Kinetic modeling

As processes had been excluded by covering the soil with sand in the field study, kinetic evaluation was performed according to FOCUS kinetics as recommended by EFSA [*EFSA (2014): Guidance Document for evaluating laboratory and field dissipation studies to obtain $DegT_{50}$ values of active substances of plant protection products and transformation products of these active substances in soil. EFSA Journal 2014;12(5):3662, 37 pp. doi: 10.2903/j.efsa.2014.3662*].

The software package KinGUI version 2.2014.224.1704 was used for parameter fitting. The error tolerance and the number of iterations of the optimization tool (IRLS) were set to the default values of 1×10^{-6} and 100, respectively.

Data preparation for kinetic evaluation was based on raw data from laboratory. For the parent substance, the sum of residues of the alpha-cypermethrin isomers cis-1 and cis-2 was considered. The sums were calculated by adding individual values above LOQ (0.001 mg kg^{-1}, related to dry weight of the soil samples); if one individual value was below LOQ but above LOD (0.0003 mg kg^{-1}, related to dry weight of the soil samples), a value of 0.0005 mg kg^{-1} (half of LOQ) was taken for calculation; values below LOD were taken as 0.0 mg kg^{-1}. For the sum of the two isomers a LOQ of 0.002 mg kg^{-1} and a LOD 0.0006 mg kg^{-1} (two times the individual LOQ or LOD) was considered for further processing of the parent data.

For the trials in Bulgaria and Spain the metabolites 3-PBA and the cis isomer of DCVA were considered for the evaluation. The trans isomers of alpha-cypermethrin and DCVA were not included due to their low detection and therefore negligible influence.

Datasets were prepared for kinetic evaluation as follows:

- Values below LOQ were treated as recommended by the FOCUS workgroup [*FOCUS (2006)*]. Accordingly, values between LOQ and LOD were set to the mean of LOQ and LOD (parent: 0.0013 mg kg^{-1}, metabolites: 0.0007 mg kg) and values below LOD were set to half of LOD (parent: 0.0003 mg kg^{-1}, metabolites: 0.0002 mg kg^{-1}).

- For each sampling point, the concentration of a compound in the single soil layer given in mg kg^{-1} was transformed to its residue given in g ha^{-1} considering the height of the respective layer and the respective undisturbed soil bulk density for each sample as given in the study report. The total residues in the sampled subplot were calculated as the sum of residues of the single soil layers.

- For the metabolites, the residues in g ha^{-1} were transformed into parent equivalents in g a.s. ha^{-1}.

The measured data as well as resulting datasets submitted to kinetic analysis are provided in the original evaluation report.

Kinetic models included in the evaluations

For each data set, the kinetic models proposed by FOCUS Kinetics were tested. The recommended kinetic models, i.e. single-first order (SFO), First-order multi-compartment (FOMC), Hockey Stick (HS) and Double first-order in parallel (DFOP), were applied to the alpha-cypermethrin data.

A kinetic model is considered appropriate if the residuals are randomly distributed around zero, the χ^2 error indicates a sufficient quality of the fit (e.g. value is ideally <15 % but may be higher if the visual fit represents the degradation behavior well) and the estimated degradation parameters differ significantly from zero.

The metabolites were subsequently added to the appropriate kinetic model for the parent considering the SFO kinetic model. Simultaneous formation of the degradation products from the parent was assumed for the kinetic evaluation.

In order to derive modeling endpoints, kinetic evaluation was performed on the time-step normalized data set.

Normalization procedure

Evaluation of the suitability of field dissipation data for normalization was performed according to the evaluation criteria for normalization compiled by the Dutch regulatory authority (CTGB criteria).

The time-step normalization procedure was carried out for all field trials by reducing or increasing day lengths depending on soil temperature and moisture by means of correction factors (f_{temp} and f_{moist}) identical to those used in most regulatory leaching models. Daily soil moisture and soil temperature values were calculated by FOCUS-PEARL 4.4.4 using weather data available from on-site weather stations and soil characteristics reported in the original study report.

Temperature correction factors (f_{temp}) were determined according to Equation Equation 7.1.2.2.1-1 c to account for differences between actual daily soil temperatures as calculated by PEARL and a reference temperature of 20°C using the Q_{10} approach and considering a Q_{10} value of 2.58.

Moisture correction factors (f_{moist}) were determined according to Equation 7.1.2.2.1-1 d to account for differences between actual daily soil moisture as calculated by PEARL and the reference soil moisture at field capacity (pF 2).

The normalized day lengths were derived according to Equation 7.1.2.2.1-1 a and normalized sampling days (D_{norm}) after application were calculated by cumulatively summing up normalized day lengths according to Equation 7.1.2.2.1-1 b.

Equation 7.1.2.2.1-1:Calculation of normalized day length based on combination of soil moisture and soil temperature correction factors

a)
$$D_{norm} = D * f_{temp} * f_{moisture}$$

b)
$$t_i = \sum_{t=1}^{i-1} D_{norm}$$

with:

t_i =	Time from application till sampling at day i	[d]
D_{norm} =	Normalized day length (20°C, pF2)	[d]
i =	Time span between application and sampling	[d]

c)
$$f_{temp} = \begin{cases} Q_{10}^{\frac{Tact-Tref}{10}} & \text{for } T_{act} > 0°C \\ 0 & \text{for } T_{act} \leq 0°C \end{cases}$$

d)
$$f_{moist} = \begin{cases} \left(\frac{\theta_{act}}{\theta_{ref}}\right)^B & \text{for } \theta_{ref} > \theta_{act} \\ 1 & \text{for } \theta_{ref} \leq \theta_{act} \end{cases}$$

with:

D_{norm} =	normalized day length (temperature and moisture corrected)	[days]
D =	actual day length (1 d)	[days]
f_{temp} =	temperature correction factor	[-]
f_{moist} =	moisture correction factor	[-]
T_{act} =	actual soil temperature	[C°]
T_{ref} =	reference temperature (20°C)	[C°]
Q_{10}=	factor of increase of degradation rate with an increase in temperature of 10°C (Q_{10} = 2.58)	[-]
θ_{act} =	actual soil moisture	[m^3 m^{-3}]
θ_{ref} =	reference soil moisture at pF2	[m^3 m^{-3}]
B =	exponent of the moisture response function, B = 0.7	[-]

Table 7.1.3.1.2-1 shows the field sampling dates for the trial locations and the normalized (20°C, pF2) day lengths based on soil moisture and soil temperature data as simulated by FOCUS-PEARL 4.4.4.

II. RESULTS AND DISCUSSION

The SFO model was appropriate to derive modeling endpoints for alpha-cypermethrin and its metabolites DCVA and 3-PBA for field trials L120555 (DE1), L120556 (DE2), L120558 (BG) and L120559 (ES). HS model was appropriate to derive modeling endpoints for alpha-cypermethrin from field trial L120557 (UK) and FOMC model was used to derive modeling endpoints from field trial L120560 (FR). A summary of the adequate $DegT_{50}$ values, as well as of the formation fractions for the metabolites, is given in Table 7.1.2.2.1-37 to Table 7.1.2.2.1-39.

Table 7.1.2.2.1-37: Summary of modeling endpoints of alpha-cypermethrin

Field trial	Soil type (USDA)	Best-fit kinetic model	χ^2	$DegT_{50}$ [d]
L120555 (DE1)	Sandy loam	SFO	11.0	46.1
L120556 (DE2)	Silt loam	SFO	15.5	16.5

III. CONCLUSION

Kinetic evaluation of six field trials with alpha-cypermethrin was conducted in order to derive reliable normalized modeling endpoints according to the current guidance of the FOCUS workgroup on degradation kinetics. The SFO model was appropriate to derive modeling endpoints for alpha-cypermethrin and its metabolites DCVA and 3-PBA for field trials L120555 (DE1), L120556 (DE2), L120558 (BG) and L120559 (ES). HS model was appropriate to derive modeling endpoints for alpha-cypermethrin from field trial L120557 (UK) and FOMC model was used to derive modeling endpoints from field trial L120560 (FR).

Kinetic evaluation of the time-step normalized dataset (20°C, pF2) resulted in normalized field half-lives ($DegT_{50}$) for alpha-cypermethrin between 11.7 and 114.1 days, for DCVA between 16.0 and 32.4 days and for 3-PBA between 17.1 and 35.8 days.

CA 7.1.2.2.2 Soil accumulation studies

Due to the fast degradation of alpha-cypermethrin no accumulation study in soil is required.

CA 7.1.3 Adsorption and desorption in soil

CA 7.1.3.1 Adsorption and desorption

Two adsorption/desorption studies were reviewed in the submission of alpha-cypermethrin (see Table 7.1.3.1-1):

1. Stevens J.K.B. (1981) Cypermethrin: Adsorption and desorption in soil
Study performed with cypermethrin in one soil, not following current guidance. The study result can only be interpreted in a qualitative way.

2. Hill A.D. (1993) [Benzyl- ^{14}C] WL85871 (FASTAC): Adsorption desorption in three soils
The current endpoints were derived from this study. The study has the following deficiencies: Only three soils were used. Questions about the solubility of alpha-cypermethrin could not be solved. It seems that the highest concentration used in the study exceeded the solubility of the compound. A very strong decline in sorption was observed for the highest concentration. In the determination of the Freundlich exponent only four data points were measured covering approximately a factor of 10. The isotherms did not show a good fit.

Therefore a new study was conducted with alpha-cypermethrin in five soils. Due to the low solubility of the compound it was decided to give up an attempt to determine the Freundlich exponent. This new study (Heinz N. 2014/1162672) was used to propose a new Koc value for risk assessment.

In addition a study with DCVA was conducted (Malinski D. S., 2004/5000486) and is presented under CA 7.1.3.1.2/1.

Table 7.1.3.1-1: List of peer reviewed soil adsorption/desorption studies performed with (alpha-) cypermethrin or cypermethrin metabolite 3-PBA

CA 7.1.3.1.1 Adsorption and desorption of the active substance

Report: CA 7.1.3.1.1/1
Heinz N., 2014a
Determination of Adsorption and Desorption Behavior of BAS 310 I (Alpha-Cypermethrin) in 5 Soils (OECD Guideline 106)
2014/1162672
Guidelines: OECD 106
GLP: yes
(certified by Landesanstalt fuer Umwelt, Messungen und Naturschutz, Baden-Württemberg, Karlsruhe, Germany)

Executive Summary

In laboratory experiments the adsorption behavior of alpha-cypermethrin (BAS 310 I) was investigated on five European soils. The five tested soils covered a range of pH ($CaCl_2$) from 5.4 to 7.4, a range of organic carbon content from 0.67 to 1.72%, and three different USDA textural classes: two loamy fine sands, two sandy loams, and one loam. Due to the low water solubility of alpha-cypermethrin, adsorption was only tested for one concentration level (3 ng mL^{-1}). Hence, no adsorption or desorption isotherm was determined. The application solution was prepared in acetone with a nominal concentration of 10 µg mL^{-1} of the test item. The ratio of soil versus test solution was 1/100, and the measurements were performed at the adsorption equilibrium time of 2 h.

Sorption of alpha-cypermethrin to soil proceeded fast, expressed by about 95% of the initially applied amount of the test item adsorbed after an equilibration time of 2 h. Hence, almost the entire applied amount (≥ 95%) of alpha-cypermethrin was accounted to the fraction sorbed to the soil phase. Calculated mean distribution coefficients (K_d) ranged from 2366 mL g^{-1} (LUFA 2.3) to 4362 mL g^{-1} (LUFA 2.2). Distribution coefficients normalized to the fraction of organic carbon in the soils (K_{OC}) ranged from 228622 mL g^{-1} (Bruch West) to 353100 mL g^{-1} (LUFA 2.3).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test item: alpha-cypermethrin (BAS 310 I)
Reg. No.: 4078193
Batch No.: L80-24
Chemical name (IUPAC): Racemate of (S)-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Chemical purity: 99.4%
Molecular weight: 416.3 g mol^{-1}

2. Soils

The study was conducted with five different soils originating from Europe. The physico-chemical properties of the soils are provided in Table 7.1.3.1.1-1.

Table 7.1.3.1.1-1: Characterization of soils used to determine the adsorption behavior of alpha-cypermethrin

Soil designation Origin	**LUFA 2.2 Germany**	**LUFA 2.3 Germany**	**Bruch West Germany**	**Li10 Germany**	**Fiorentino Poggio Renatico 1 Italy**

B. STUDY DESIGN

1. Experimental conditions

Preliminary tests: adsorption kinetics and soil / solution ratio

A preliminary experiment was run with two soils (LUFA 2.2 and Fiorentino Poggio Renatico 1) to determine the time needed to establish equilibrium conditions and to find the optimal soil / solution ratio for the adsorption tests. The experiments were run with a soil / solution ratio of 1/100. The test was performed using 30 µL application solution (10 µg mL^{-1} alpha-cypermethrin in acetone). The vials were protected from light and shaken at 19 - 20°C for 2, 4, 6 and 24 h. The soil / solution suspension was then centrifuged and decanted. An aliquot of the supernatant was sampled and the concentration of test item in the $CaCl_2$ solution was determined by gas chromatography coupled with mass spectrometry (GC-MS).

The parallel method was used with determination of the amount adsorbed (direct method) via solvent extraction of the soil pellets. All experiments were performed in duplicates.

Results of this first trial revealed that the adsorption equilibrium was reached fast (≤ 2 h). The soil / solution ratio of 1/100 led to significant adsorption of about 95% of the initially applied amount of the test item.

Stability and adsorption of the test substance

Due to the low solubility of the test item in water (maximal 3 µg L^{-1}) and a high adsorption to soil, no adsorption or desorption isotherms could be determined in this study. Hence, the stability test, which is typically performed during the pre-tests, corresponds to the adsorption test.

The adsorption kinetics test was performed as described for the preliminary test with the three remaining soils (Bruch West, Li10, and LUFA 2.3), but with 2 h equilibration time only.

Stability of alpha-cypermethrin in aqueous $CaCl_2$ solution was demonstrated by acceptable results for adsorption controls obtained by GC-MS analyses.

Instability of alpha-cypermethrin in soil/$CaCl_2$ solution was demonstrated by decreasing mass balances in adsorption kinetic tests, indicating degradation or formation of bound residues.

Control samples with only the test item in aqueous 0.01 M $CaCl_2$ solution (adsorption controls) were used to elucidate a potential adsorption of the test item to the surface of the test vessels.

In addition, experiments were conducted in order to estimate the adsorption to test vessel surface in presence of soil. Therefore, two experiments were performed in parallel, each one in duplicate. 1.0 g of soil was agitated with 100 mL solution for 6 h. Afterwards, phases were separated by centrifugation and decantation. One sample of the soil pellet was extracted with solvent directly in the test vessel. From the second soil sample, the soil pellet was removed as good as possible and transferred directly into extraction solvent present in another vessel equivalent to the test vessel. The difference in detected amounts of the test item between the two samples was used to estimate the surface adsorption in the test vessels.

2. Description of analytical procedures

The parallel method was performed, including the determination of the amount of the test item in the aqueous phase, as well as the determination of the amount adsorbed to soil via solvent extraction.

Principle of the methods:

To analyze alpha-cypermethrin in the aqueous phase, soil suspensions were centrifuged (5 min, 4000 rpm), decanted, and adjusted to pH 5 with formic acid. Supernatants were extracted two times with 10 mL portions of cyclohexane by mechanical shaking. The organic layers were combined and 0.2 mL of an internal standard solution (10 mg mL^{-1} lambda-cyhalothrin in toluene) was added. The extract was concentrated to the final volume of 0.2 mL and subsequently analyzed by GC-MS (with negative chemical ionization: NCI). The method has a limit of quantification (LOQ) of 0.03 ng mL^{-1} in $CaCl_2$ solution, for soil 3 ng g^{-1}. The limit of detection (LOD) in $CaCl_2$ solution is < 0.0002 ng mL^{-1} (< 0.2 pg mL^{-1}), for soil < 0.2 ng g^{-1} (< 200 pg g^{-1}).

For soil analysis, soil samples (1.0 g) were extracted with 10 mL acetonitrile/water (7:3, v/v) on a mechanical shaker (10 min) followed by sonication (5 min) in an ultrasonic bath. After extraction, the tube was centrifuged at 4000 rpm (5 min). The extraction was repeated two times with each 10 mL acetonitrile containing 0.1% formic acid. The three extracts were combined. A 5.0 mL aliquot from the extract and 5 mL of water were partitioned with 30 mL of cyclohexane by shaking 30 min on a horizontal shaker. After centrifugation (1 min, 4000 rpm) the organic layer was separated and 0.5 mL of the internal standard solution (10 mg mL^{-1} lambda-cyhalothrin in toluene) was added. The extract was concentrated to a final volume of 0.5 mL for subsequent GC-MS analysis (with negative chemical ionization: NCI).

To account for the amount of test item adsorbed to the test vessel surface in the presence of soil, glass centrifuge vials (used for adsorption kinetics experiments) were extracted two times with 10 mL of ethyl acetate on a horizontal shaker (10 min) and sonication (5 min) in an ultrasonic bath. The combined organic layer was spiked with 0.2 mL of the internal standard. After concentration to the final volume of 0.2 mL, samples were analyzed by GC-MS (with negative chemical ionization: NCI).

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The analytical methods for the determination of the test item in the aqueous phase, as well as for the determination in soil extracts were validated within this study. Both methods revealed acceptable average recoveries (71 - 96%) and relative standard deviations (RSD; ≤ 20%) for the dose levels of 15.0 and 150 ng mL^{-1} for $CaCl_2$ solution, as well as 3.0 and 300 ng g^{-1} for soil, respectively.

In the adsorption test, the average recovery values ($CaCl_2$ solution plus soil extract) ranged from 82 to 88%. For soil LUFA 2.3, the average recovery was low, exhibiting 54% of the initially applied amount of the test item, and was accounted for degradation or formation of bound residues.

B. FINDINGS

Based on the results obtained, the applied analytical methods are considered valid for the determination of alpha-cypermethrin in $CaCl_2$ solution and in soil with a validated LOQ of 0.03 ng mL^{-1} and 3 ng g^{-1}, respectively.

Results of the adsorption equilibrium test carried out with alpha-cypermethrin indicated that the adsorption equilibrium was reached within 2 h.

Results of control samples (adsorption controls), where the test item was applied to $CaCl_2$ solution incubated without soil, revealed that alpha-cypermethrin was not sorbed to the wall of the test vessels in the absence of soil (average recovery 92%; RSD ≤ 11%).

In addition, experiments with soil were conducted in order to estimate the adsorption to test vessel surface in presence of soil. As a result, the soil samples extracted in the experimental vessels show, soil related, slightly higher concentrations than the comparable soil samples, where the soil was removed and extracted out of the experimental vessel. However, considering this variability over all soils and comparing it against relative standard variation percentages of recovery rates during the course of soil residue analysis, these differences are of no significance.

Sorption of alpha-cypermethrin to soil proceeded fast. This was expressed by about 95% of the initially applied amount of the test item adsorbed to the soil phase after an equilibration time of 2 h. Hence, almost the entire applied amount (≥ 95%) of alpha-cypermethrin was accounted to the fraction sorbed to the soil phase. Calculated mean distribution coefficients (K_d) ranged from 2366 mL g^{-1} (LUFA 2.3) to 4362 mL g^{-1} (LUFA 2.2). Distribution coefficients normalized to the fraction of organic carbon in the soils (K_{OC}) ranged from 228622 mL g^{-1} (Bruch West) to 353100 mL g^{-1} (LUFA 2.3). Calculated K_d as well as K_{OC} values are presented in Table 7.1.3.1.1-2.

Table 7.1.3.1.1-2: Measured equilibrium concentrations and calculated distribution coefficients K_d and K_{OC} of alpha-cypermethrin

Soil	Soil Type (USDA)	Org. C [%]	pH ($CaCl_2$)	Adsorption	
				K_d [mL g^{-1}]	K_{OC} [mL g^{-1}]
LUFA 2.3	loamy fine sand	0.67	5.4	2366	353100
LUFA 2.2	sandy loam	1.72	5.8	4362	253632
Bruch West	sandy loam	1.62	7.1	3704	228622
Li10	loamy fine sand	0.95	6.3	3181	334804
Fiorentino Poggio Renatico 1	loam	1.07	7.4	2927	273519

III. CONCLUSION

The adsorption behavior of alpha-cypermethrin was determined on five European soils. The soils covered a range of pH from 5.4 to 7.4 and a range of organic carbon content from 0.67 to 1.72%. The soils were classified by USDA scheme into 3 different textural classes: two loamy fine sands, two sandy loams, and one loam.

The test item was fast and nearly completely adsorbed to the soil phase. This was expressed by high distribution coefficients with K_d values of 2366 to 4362 mL g^{-1}, as well as high K_{OC} values of 228622 to 353100 mL g^{-1}.

CA 7.1.3.1.2 Adsorption and desorption of metabolites, breakdown and reaction products

One adsorption/desorption study performed with alpha-cypermethrin metabolite 3-PBA was submitted and evaluated previously.

Holman J. C. 2002
^{14}C-CL 206128 (Metabolite of BAS 310 I, alphacypermethrin): Adsorption/Desorption on Soils
BASF Doc ID: AL-620-015
GLP: yes

Summary
The objective of this study was to determine the adsorption/desorption behavior of the alpha-cypermethrin (BAS 310 I) metabolite CL 206128 (3-PBA) on four soils (two silty loam soils, a sandy loam soil, and a loamy sand soil) collected in Germany,

The soil adsorption/desorption study was conducted at 20°C using the batch equilibrium method specified in OECD Guideline 106. ^{14}C-labeled 3-PBA was applied at nominal concentrations of approximately 0.05, 0.1, 0.5, 1, and 5 mg L^{-1} to 0.01 M $CaCl_2$ solution. The definitive tests were conducted in duplicate at a 1:1 soil : solution ratio and a sorption/desorption equilibrium time of 48 hours.

^{14}C-3-PBA was moderately adsorbed to all of the soils tested. The soil organic carbon normalized Freundlich adsorption coefficients (K_{OC}) values for 3-PBA ranged from 46 to 91, with an average K_{OC} of 73. Freundlich adsorption coefficients (K_{Fads}) ranged from 0.897 to 2.076 with 1/n values ranging from 0.70 to 0.86. Desorption coefficients (K_{Fdes}) ranged from 1.159 to 1.836 with 1/n values ranging from 0.58 to 0.79. A strong concentration dependence on adsorption was observed.

Report: CA 7.1.3.1.2/1
Malinsky D.S., 2005a
Adsorption/desorption of BAS 310 I metabolite (CL 912554) on soil
2004/5000486
Guidelines: EPA 163-1, EEC 91/414
GLP: yes
(certified by United States Environmental Protection Agency)

Executive Summary

The adsorption/desorption potential of CL 912554 (DCVA) was determined in five European soils, which included two loams, two loamy sands and one silt. The adsorption/desorption of ^{14}C-CL 912554 was determined using the batch equilibrium method at CL 912554 concentrations of approximately 0.250, 0.502, 1.01 and 2.10 µg a.s. g^{-1} of soil. The soils from all treatments were extracted with acetonitrile after the desorption phase of the study. The mass balance for the test soils ranged from 90 to 95% of the total applied radioactivity (TAR).

The % TAR of CL 912554 sorbed by the Bonnut, Chateauroux, Thoree les Pins, Pithiviers and Ploudalmezeau soils were 44.37, 28.07, 45.38, 18.63 and 27.76, respectively. Adsorption (K_{ads}) and desorption coefficients (K_{des}) were determined using the Freundlich equation. The K_{ads} values for the Bonnut, Chateauroux, Thoree les Pins, Pithiviers and Ploudalmezeau soils were 1.718, 0.743, 2.223, 0.514 and 0.711, respectively. There is a good correlation between the % TAR sorbed by the soils and the calculated K_{ads} values. The higher % TAR sorbed values correlated with higher K_{ads} values. The organic carbon normalized adsorption constants $K_{f,oc}$ derived from the K_{ads} values for the Bonnut, Chateauroux, Thoree les Pins, Pithiviers and Ploudalmezeau soils were 191, 57, 318, 37, and 47, respectively. These values indicate that CL 912554 will have medium mobility in Chateauroux, Pithiviers and Ploudalmezeau soils and low mobility in Bonnut and Thoree les Pins soils.
The K_{des} values (cycle 1) for the Bonnut, Chateauroux, Thoree les Pins, Pithiviers and Ploudalmezeau soils were 1.07, 1.10, 1.02, 1.03 and 1.09, respectively. All K_{des} values obtained for desorption cycle 2 were fairly similar to the values observed for desorption cycle 1.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test item:	CL 912554 (DCVA)
Reg. No.:	4080830
Batch No.:	812-0101
Chemical name (IUPAC):	cis-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylic acid
Chemical purity:	99.9%
Molecular weight:	209.07 g mol^{-1}
Position of radiolabel:	cyclopropyl-1-^{14}C
Specific radioactivity:	2.68 MBq mg^{-1}
Radiochemical purity:	99.8% (by Radio-HPLC)

2. Soils

The study was conducted with five different soils originating from Europe. The physico-chemical properties of the soils are provided in Table 7.1.3.1.2-1. All soil characterization data was archived with BASF Study 131210 [*SINGH, MAHATAM, TROLLINGER, JEWEL (2003): Adsorption of ^{14}C-BAS 712 H and ^{14}C-4110778 (Metabolite of BAS 712 H) on soil, BASF DocID 2003/5000136*].

Table 7.1.3.1.2-1: Characterization of soils used to determine the adsorption/desorption behavior of CL 912554 (DCVA; alpha-cypermethrin metabolite)

Soil designation Origin	Bonnut France	Chateauroux France	Thoree les pins France	Pithiviers France	Ploudalmezeau France

B. STUDY DESIGN

1. Experimental conditions

Preliminary tests: recovery and stability of the test item

The recovery/stability experiment was attempted several times due to the instability of ^{14}C-CL 912554 (DCVA) when exposed to light. One test solution was applied (uncovered) to deionized water to check if $CaCl_2$ contributed to the degradation of ^{14}C-CL 912554. For each test solution 125 µL of a diluted stock solution was added to 20 mL of 0.01M $CaCl_2$ solution. The concentration of ^{14}C-CL 912554 in each test solution was approximately 1.0 µg mL^{-1}. Immediately after treatment, the test solutions were assayed by liquid scintillation counting (LSC) to determine the % TAR in the solutions. Three of the test solutions were left uncovered and one was covered with aluminum foil. The test vessels were capped and placed on a shaker maintained at 20°C in the dark. After 8 hours of shaking at 140 rpm, the samples were centrifuged at 2,000 rpm for 5 minutes.
Aliquots for HPLC analysis were removed after 8, 24 and 48 hours. After 8 hours, results of HPLC analysis indicated that ^{14}C-CL 912554 in two of the three uncovered test vessels was completely degraded. In the remaining uncovered test solution ^{14}C-CL 912554 was degraded entirely after 24 h. In the $CaCl_2$ solution sample which was covered with aluminum foil) no degradation of ^{14}C-CL 912554 could be detected. The recovery remained above 101% TAR for the duration of the experiment in the covered vessel. These results indicate that ^{14}C-CL 912554 is not adsorbed to the vessel and is stable in 0.01M $CaCl_2$ solution for at least 48 hours (in the dark).

Preliminary tests: adsorption kinetics

To determine the duration to reach adsorption equilibrium a test solution was prepared by adding 1.5 mL of a diluted stock solution to 250 mL of 0.01M $CaCl_2$ solution. The concentration of ^{14}C-CL 912554 was 1.0 µg CL 912554 per mL.
The adsorption equilibrium experiment was conducted with all five soils in duplicate. Approximately 10 g of each soil was weighed into a test vessel and 20 mL of the test solution was added. The concentration of ^{14}C-CL 912554 applied to all soils was about 2.0 µg g^{-1} soil (dry weight equivalent). The test vessels were capped, covered with foil, and shaken at 140 rpm and 20°C in the dark. The % TAR of ^{14}C-CL 912554 adsorbed to the soils was determined after 4, 8, 24 and 48 hours of shaking. At the respective time interval, the soil phase and the aqueous phase were separated by centrifugation and the supernatants were radio-assayed by LSC to estimate the amount of radioactivity (% TAR) present in the supernatants.

Results of the LSC analysis of the supernatants indicated that adsorption equilibrium was reached after 48 hours. The test item was identified in the soil suspensions incubated for 24 hours by radio-HPLC.

Adsorption experiments

Three adsorption experiments were conducted. The first adsorption experiment was conducted with all five soils at concentrations of the test item of about 0.250, 0.502, 1.01 and 2.10 µg g^{-1} soil. The experiment was conducted in duplicate for each applied concentration and for a period of 48 hours.
Four test solutions were prepared with four different concentrations. The respective test solutions were prepared in 0.01 M $CaCl_2$ solution. The actual concentration was determined by LSC.
Approximately 10 g aliquots of each soil type were weighed into 40 vessels (5 soils, 4 concentrations, duplicates). To each test vessel containing the test soils 20 mL aliquots of the respective test solutions was added representing a soil to solution ratio of 1:2. After application of the respective test solution, the test vessels were capped, covered in foil, and shaken at 140 rpm and 20±1°C in the dark. After 48 hours shaking, the soil suspensions were centrifuged and aliquots of the supernatants were radio-assayed by LSC to determine the % TAR in the supernatants. The supernatants were stored in a refrigerator for later gravimetrically measurement.
Aliquots from the high dose sample supernatants were analyzed by HPLC to determine the nature of the radioactivity.

Desorption experiments

Desorption experiments were conducted for all five soils and four concentrations. After the adsorption step 20 mL of 0.01 M $CaCl_2$ was added to centrifuged and decanted soil residues. The samples were shaken again at 140 rpm and 20±1°C in the dark. After 24 hours shaking, the samples were centrifuged and aliquots were assayed by LSC to estimate the radioactivity present in the desorption supernatants. A second desorption cycle with fresh 0.01 M $CaCl_2$ solution was performed applying the same conditions. The supernatants of both desorption cycles were stored in a refrigerator for later gravimetrically measurement.
After the two desorption cycles, soil residues were extracted with 20 mL acetonitrile by shaking at 140 rpm and 20±1°C in the dark. After 24 hours shaking, the samples were centrifuged and aliquots of the acetonitrile supernatants were analyzed by LSC. Supernatant volumes had to be redetermined due to evaporation losses during refrigerator storage.
The residual soil samples were air-dried at room temperature under a fume hood. The soil residues were homogenized and aliquots were analyzed by combustion. The evolved $^{14}CO_2$ was trapped in a liquid scintillation cocktail and analyzed by LSC to determine the radioactivity remaining in soils after the adsorption and desorption experiments.

2. Description of analytical procedures

After centrifugation of the soil suspensions, the supernatant of all samples (pretests, adsorption and desorption experiment) were analyzed by LSC. In addition, aliquots of the soil suspension comprising the highest concentration of the test item (2.10 µg g^{-1} soil) were analyzed by radio-HPLC.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The mass balance for the five soils used in the study ranged from 90 to 95% TAR comprising a relative standard deviation of < 4%.

B. FINDINGS

Adsorption data for the five European soils are presented in Table 7.1.3.1.2-2. Adsorption coefficients K_{ads} for Bonnut, Chateauroux, Thoree les Pins, Pithiviers, and Ploudalmezeau soil were 1.718, 0.743, 2.223, 0.514 and 0.711, respectively. There is good positive linear correlation between the % TAR adsorbed to the soils and the K_{ads} values obtained by the Freundlich equation. The most adsorptive soils for ^{14}C-CL 912554 (DCVA) were Thoree les Pins and Bonnut with 45.38% TAR and 44.37% TAR, respectively. The soils featuring a lower pH value exhibited higher % TAR adsorption values. Organic carbon normalized adsorption coefficients (K_{OC}) for Bonnut, Chateauroux, Thoree les Pins, Pithiviers and Ploudalmezeau were 329.1, 98.5, 547.5, 63.3 and 81.7, respectively. These K_{OC} values indicate that CL 912554 will have medium mobility in Chateauroux, Pithiviers and Ploudalmezeau soils and low mobility in Bonnut and Thoree les Pins soils.

Desorption coefficients (K_{des}; cycle 1) for the five soil ranged from 1.02 to 1.10 (Table 7.1.3.1.2-3). All K_{des} values obtained for desorption cycle 2 were fairly similar to the values observed for desorption cycle 1. R_{des1} values, expressing the percentage of desorbed ^{14}C-CL 912554 during 24 h of shaking, were about 0.16 and 0.00 for Chateauroux and Pithiviers soil, respectively (Table 7.1.3.1.2-4). Results indicate limited desorption of CL 912554 from these soil types. Bonnut and Thoree les Pins had R_{des1} values of 0.43 and 0.31, respectively, which indicate high desorption possibility of CL 912554 to these soils. The R_{des1} value for Ploudalmezeau was 0.24, which suggest moderate desorption of adsorbed CL 912554 from this soil.

The acetonitrile extracts from Bonnut, Chateauroux, Thoree les Pins, Pithiviers, and Ploudalmezeau soil contained an average of 13.16, 8.21, 22.54, 5.76, and 5.72% TAR, respectively. The % TAR still bound to Bonnut, Chateauroux, Thoree les Pins, Pithiviers and Ploudalmezeau soil accounted for 9.62, 17.12, 8.40, 13.88, and 12.19% TAR, respectively. These results demonstrate that some amounts of CL 912554 bound to the soils cannot be desorbed. The highly adsorptive soils (Bonnut and Thoree les Pins) exhibited smaller amounts of non-extractable CL 912554 compared to the moderately adsorptive soils (Chateauroux, Pithiviers and Ploudalmezeau).

Table 7.1.3.1.2-2: Soil adsorption data of CL 912554 (DCVA)

Soil	Intercept (log K_{ads})	K_{ads}	Slope (1/n)	R^2
Bonnut	0.235	1.718	0.836	0.9997
Chateauroux	-0.129	0.743	0.692	0.9948
Thoree les Pins	0.347	2.223	0.889	0.9969
Pithiviers	-0.289	0.514	0.754	0.9784
Ploudalmezeau	-0.148	0.711	0.728	0.9826

Pithiviers	0.00	0.30	37
Ploudalmezeau	0.24	0.27	47

[a] Recalulated values; $K_{f,oc}$ from study were calculated erroneously.

III. CONCLUSION

The adsorption/desorption behavior of CL 912554 (DCVA) was determined in five European soils, which included two loams, two loamy sands and one silt. These soils covered a pH range from 4.4 to 7.1 and a range of organic carbon content from 0.7% to 1.5%.

The $K_{f,oc}$ values for CL 912554 were 191 and 318 for both sandy loam (Bonnut and Thoree les Pins) soils. These results suggest that CL 912554 is moderately adsorbed to sandy loam soils types. The $K_{f,oc}$ values for the loam (Chateauroux, Pithiviers, and Ploudalmezeau) soils ranged from about 37 to 57, which suggest that CL 91254 is slightly adsorbed to these soil types.

R_{des1} values for Chateauroux and Pithiviers soils were about 0.16 and 0.00, respectively. These results indicate limited desorption of CL 912554 from these soil types. Bonnut and Thoree les Pins had R_{des1} values of 0.43 and 0.31, respectively, which indicate a comparatively high desorption capacity of CL 912554 from these soils. The R_{des1} value for Ploudalmezeau was 0.24, which suggest moderate desorption of adsorbed CL 912554 from this soil.

Report:	CA 7.1.3.1.2/2 Walter W., 2014a Determination of Adsorption Behavior of M310I017 cis (metabolite of BAS 310 I, Alpha-Cypermethrin) in 5 Soils (OECD Guideline 106) 2014/1315294
Guidelines:	OECD Guideline 106
GLP:	yes (certified by Landesanstalt fuer Umwelt, Messungen und Naturschutz, Baden-Württemberg, Karlsruhe, Germany)

Executive Summary

In laboratory experiments the adsorption behavior of alpha-cypermethrin metabolite M310I017 cis (containing trans isomers) was investigated on five European soils. The five tested soils covered a range of pH ($CaCl_2$) from 5.4 to 7.4, a range of organic carbon content from 0.67 to 1.72%, and three different USDA textural classes: two loamy fine sands, two sandy loams, and one loam. Due to the low water solubility of M310I017 (cis/trans), adsorption was only tested for one concentration level (25 ng mL^{-1}). Hence, no adsorption or desorption isotherm were determined. The ratio of soil versus test solution was 1/50, and the measurements were performed at the adsorption equilibrium time of 4 h.

Sorption of M310I017 cis to soil proceeded fast, expressed by ≥ 96% of the initially applied amount of the test item adsorbed after an equilibration time of 4 h. Hence, almost the entire applied amount of the test item was accounted to the fraction sorbed to the soil phase. Calculated mean distribution coefficients (K_d) ranged from 1738 mL g^{-1} (LUFA 2.3) to 3914 mL g^{-1} (Fiorentino Poggio Renatico 1). Distribution coefficients normalized to the fraction of organic carbon in the soils (K_{OC}) ranged from 139148 mL g^{-1} (LUFA 2.2) to 365806 mL g^{-1} (Fiorentino Poggio Renatico 1).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test item:	M310I017 cis (metabolite of alpha-cypermethrin)
Reg. No.:	6009306
Batch No.:	L82-159
Chemical name (IUPAC):	cyano[3-(4-hydroxyphenoxy)phenyl]methyl (1RS,3RS)-3-(2,2-dichloroethenyl)-2,2-dimethylcyclopropanecarboxylate
Chemical purity:	48.5%
Molecular weight:	432.3 g mol^{-1}

Beside cis isomer metabolites (containing cis-1 and cis-2 isomers), the test item contained an equivalent portion of [redacted] Finally, the sum of all of them was tested.

2. Soils

The study was conducted with five different soils originating from Europe. The physico-chemical properties of the soils are provided in Table 7.1.3.1.2-5.

B. STUDY DESIGN

1. Experimental conditions

Preliminary tests: Determination of solubility, adsorption kinetics, and soil/solution ratio

The solubility of the test item (M310I017 cis/trans) in water was tested in four experiments applying the column elution method (OECD 105) with demineralized water and demineralized water containing 0.1% acetonitrile at flow rates of 0.2 and 0.4 mL min^{-1}. The solubility in water was determined to be of about 72 µg mL^{-1} at 0.2 mL min^{-1} flow rate at 20°C and slightly higher when containing 0.1% acetonitrile.

Adsorption was assumed to be rather high and the analytes stability appeared to be questionable during equilibration time of 24 h. Therefore, both the direct (i.e. determination in 0.01 M $CaCl_2$ aqueous phase and in soil by appropriate solvent extraction) and the parallel (i.e. individual soil/solution samples) method procedures were used.

A preliminary experiment was run with two soils (LUFA 2.2 and Fiorentino Poggio Renatico 1) to determine the time needed to establish equilibrium conditions and to find the optimal soil/solution ratio for the adsorption tests. The experiments were run with a soil/solution ratio of 1/50, using 1 g soil, 50 mL 0.01 M $CaCl_2$ solution in PE centrifuge vials. After equilibration, soil suspensions were treated with about 1250 ng of the test item, corresponding to an initial concentration of about 25 ng mL^{-1}. Per soil type, a total of 10 soil samples were treated (duplicates per equilibration time), plus blank soil samples without dosing for blank controls. The samples were shaken at 20 - 21°C for 2, 4, 6 and 24 h. The soil / solution suspension was then centrifuged and decanted. An aliquot of the supernatant was sampled and the concentration of the test item in the $CaCl_2$ solution was determined by high performance liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS). A complete mass balance was obtained by the extraction of the soil pellets.

The amount of the test item in the aqueous phase was too low to be measured in the preliminary adsorption tests. The test item adsorbed to a very high extend on soil and the surface of fresh centrifugation tubes used for the long high speed centrifugation (30 min at 10000 rpm) of the aqueous phase.

The percentage of adsorption to soil was stable with prolonged equilibration time (≥ 95% of the initially applied amount of the test item), reaching the plateaus after 2 h (LUFA 2.2) and 4 h (Fiorentino Poggio Renatico 1) of equilibration time. Hence, further experiments were conducted with an equilibration time of 4 h.

Stability and adsorption of the test substance

The K_d values obtained with the direct method were all > 1500 mL g^{-1}, thus indicating that adsorption/desorption isotherm experiments would lead to inaccurate results. Therefore, these experiments were not performed.

The adsorption test was performed as described for the preliminary test in duplicates for all soils (including the soils used in the pre-tests), but with 4 h equilibration time only. It was possible to determine a concentration of the test tem in the soil water phase by modifying the centrifugation procedures.

Stability of the test item in aqueous $CaCl_2$ solution was demonstrated by acceptable results for adsorption controls obtained by LC-MS/MS analyses.

Control samples (dose and adsorption controls) with only test item in aqueous 0.01 M $CaCl_2$ solution were used to elucidate a potential adsorption of the test item to the surface of the test vessels. Dose controls were analyzed right after adding solution to soil; adsorption controls were analyzed after termination of agitation together with the samples.

In addition, experiments were conducted in order to estimate the adsorption to test vessel surface in presence of soil. Therefore, two experiments were performed in parallel, each one in duplicate. 1.0 g of soil was agitated with 50 mL solution for 6 h. Afterwards, phases were separated by centrifugation and decantation. One sample of the soil pellet was extracted with solvent directly in the test vessel. From the second soil sample, the soil pellet was removed as good as possible and transferred directly into extraction solvent present in another vessel equivalent to the test vessel. The difference in detected amounts of the test item between the two samples was used to estimate the surface adsorption in the test vessels.

2. Description of analytical procedures

The parallel method was performed, including the determination of the amount of the test item in the aqueous phase (direct method), as well as the determination of the amount adsorbed to soil via solvent extraction.

Principle of the methods:

To analyze M310I017 cis in the aqueous phase, soil suspensions were transferred to glass centrifuge tubes, and separated by centrifugation (5 min, 4000 rpm). Aliquots of the supernatants were centrifuged for 30 min at 15000 rpm to remove soil particles with a diameter of > 0.2 µm. Aliquots were diluted with methanol/water 8/2 (v/v) for LC-MS/MS analysis.

In the main adsorption study, the test vessel was additionally rinsed with the supernatant after centrifugation of the soil suspensions (to transfer the remaining soil particles) to account for amounts of the test item adsorbed to the walls of the test vessels. Afterwards, the rinse was added to the centrifuge tube and was centrifuged once again to separate soil and soil water phase. As the test item adsorbed completely on the surface of the centrifugation tubes during the long high speed centrifugation of the pre-tests, this step was left out in the main adsorption experiment.

For soil analysis, soil samples (1.0 g) were extracted on a mechanical shaker (30 min) with 5 mL acetonitrile/water (1:1, v/v) containing 0.1% formic acid, followed by sonication (10 min). After extraction, the tube was centrifuged at 4000 rpm (5 min). The extraction was repeated two more times with each 5 mL acetonitrile containing 0.1% formic acid. The three extracts were combined and diluted to 20 mL with 0.1% formic acid in water. An aliquot from the pooled extract was further diluted with methanol/water 8/2 (v/v) and analyzed by LC-MS/MS.

To account for the amount of test item adsorbed to the test vessel surface in the presence of soil (main adsorption experiment), glass centrifuge vials (used for adsorption kinetics experiments) were extracted with 20 mL acetonitrile/water (1/1, v/v) on a horizontal shaker (30 min) and by sonication (10 min). An aliquot was diluted with methanol/water 8/2 (v/v) and analyzed by LC-MS/MS.

The soil extraction method, as well as the method for the determination of the test item in the aqueous phase were pre-validated using the soils LUFA 2.2 and Fiorentino Poggio Renatico 1 at two fortification levels (i.e. 25 and 2500 ng g^{-1} (soil) and 0.25 and 25 ng mL^{-1} (aqueous phase), respectively). During the experiments the soil extraction method was concurrently validated for all five soils at two fortification levels (i.e. 12.5 and 1250 ng g^{-1}).

The limit of quantification (LOQ) of the analytical methods were 0.25 µg mL^{-1} (aqueous phase) and 12.5 ng mL^{-1} (soil), respectively. Corresponding limits of detection (LOD) were 0.02 µg mL^{-1} and 0.9 ng mL^{-1} (< 10% of LOQ), respectively.

II. RESULTS AND DISCUSSION

A. MASS BALANCE

In the adsorption experiment, the average recovery values after soil extraction ranged from 95% to 107% for all soils, with the exception of soil Fiorentino Poggio Renatico 1 with only 75% recovery on average after 4 h equilibration time. This indicated degradation and/or formation of bound residues with prolonged equilibration time for this soil.

B. FINDINGS

Pre-validation of the soil extraction method, as well as the method for the determination of the test item in the aqueous phase resulted in overall average recoveries of 108% (relative standard deviation RSD: 4%) for the soil extraction and of 82% (RSD: 20%) for the method applied for the determination in the aqueous phase. During the experiments, the soil extraction method was concurrently validated for all five soils at two fortification levels (i.e. 12.5 and 1250 ng g^{-1}), resulting in an overall average recovery of 100% (RSD: 13%).

Results of the adsorption equilibrium test carried out with alpha-cypermethrin metabolite M310I017 cis indicated that the adsorption equilibrium was reached within 4 h.

Control specimens with only the test item in aqueous 0.01 M $CaCl_2$ solution (dose controls, diluted directly after fortifying and adsorption controls, diluted after appropriate equilibration time) revealed significant adsorption on the surface of the test vessels when soil is not present in the system.

Results of control samples, where the test item was applied to $CaCl_2$ solution incubated with soil revealed that adsorption on the surface of the test vessel when soil is present in the system is negligible.

Sorption of the test item to soil proceeded fast. This was expressed by ≥ 96% of the initially applied amount of the test item adsorbed to the soil phase after an equilibration time of 4 h. Hence, almost the entire applied amount of the test item was accounted to the fraction sorbed to the soil phase. Calculated mean distribution coefficients (K_d) ranged from 1738 mL g^{-1} (LUFA 2.3) to 3914 mL g^{-1} (Fiorentino Poggio Renatico 1). Distribution coefficients normalized to the fraction of organic carbon in the soils (K_{OC}) ranged from 139148 mL g^{-1} (LUFA 2.2) to 365806 mL g^{-1} (Fiorentino Poggio Renatico 1). Calculated K_d as well as K_{OC} values are presented in Table 7.1.3.1.2-6.

Table 7.1.3.1.2-6: Measured equilibrium concentrations and calculated distribution coefficients K_d and K_{OC} of M310I017 cis

Soil	Soil Type (USDA)	Org. C [%]	pH ($CaCl_2$)	Adsorption	
				K_d [mL g^{-1}]	K_{OC} [mL g^{-1}]
LUFA 2.2	sandy loam	1.72	5.8	2393	139148
LUFA 2.3	loamy fine sand	0.67	5.4	1738	259437
Bruch West	sandy loam	1.62	7.1	2819	174041
Li10	loamy fine sand	0.95	6.3	2956	311179
Fiorentino Poggio Renatico 1	loam	1.07	7.4	3914	365806

III. CONCLUSION

The adsorption behavior of alpha-cypermethrin metabolite M310I017 cis (Reg. No. 6009306; containing trans isomers) was determined on five European soils. The soils covered a range of pH from 5.4 to 7.4 and a range of organic carbon content from 0.67 to 1.72%. The soils were classified by USDA scheme into 3 different textural classes: two loamy fine sands, two sandy loams, and one loam.

The test item was fast and nearly completely adsorbed to the soil phase. This was expressed by high distribution coefficients with K_d values of 1738 to 3914 mL g^{-1}, as well as high K_{OC} values of 139148 to 365806 mL g^{-1}. Due to the high K_d values obtained for all soils and the low water solubility of the test item, no adsorption/desorption experiments were conducted.

CA 7.1.3.2 Aged sorption

No studies to investigate aged sorption were conducted with alpha-cypermethrin.

CA 7.1.4 Mobility in soil

CA 7.1.4.1 Column leaching studies

The following studies were submitted and peer-reviewed (See Table 7.1.4.1-1).

Table 7.1.4.1-1: List of peer-reviewed column leaching studies performed with cypermethrin and cypermethrin metabolites

DocID	Parent compound	Soil	Application rate [mg kg^{-1}]	Incubation temperature	Incubation period [days]	Remark

CA 7.1.4.1.1 Column leaching of the active substance

1. Standen M.E. (1977) The leaching and the degradation of the insecticide WL 43467 when applied as sheep-dip solution to soil
Study performed with formulation ingredients from a veterinary medicine study. Not useful to derive endpoints.

2. Jackson C. (1977) The leaching of WL 434567 through laboratory soil columns
Poorly documented study that shows that cypermethrin has no tendency to leach through the soil columns. Not useful to derive endpoints.

3. Stevens J.E.B. et al (1980) Cypermethrin: Mobility of cypermethrin and its degradation products in soil columns
The mobility of aged cypermethrin residues was investigated in four soils. After applying 67 cm of simulated rain less than 2 % of the applied radioactivity was detected in the leachates.

CA 7.1.4.1.2 Column leaching of metabolites, breakdown and reaction products

1. Kaufman D.D.et al. (1981) Movement of cypermethrin, decamethrin, permethrin, and their degradation products in soil (Publication)
Study focused on decametrin, but also the studies the leaching behaviour of the common metabolites DCVA, 3-PBA and 3-PBald. As expected the metabolites show mobility in soil, while the active substances do not move into deeper layers of soil. Study not useful to derive endpoints.

CA 7.1.4.2 Lysimeter studies

Due to the high sorption of the active substance to soil, no leaching studies were performed.

CA 7.1.4.3 Field leaching studies

Due to the high sorption of the active substance to soil, no field leaching studies were performed.

CA 7.2 Fate and behaviour in water and sediment

CA 7.2.1 Route and rate of degradation in aquatic systems (chemical and photochemical degradation)

A range of hydrolysis studies have been performed with cypermethrin or alpha-cypermethrin (see Table 7.2.1-1). The cypermethrin studies are listed for historical reasons and can be replaced by studies performed with alpha-cypermethrin. Data generated with alpha-cypermethrin and submitted in the previous Annex-I review gave a clear picture of the fate of alpha-cypermethrin in aquatic systems

Table 7.2.1-1: List of hydrolytic and photochemical degradation studies in aquatic systems performed with (alpha-) cypermethrin

Studies performed with cypermethrin. Not considered in evaluation

1. Takahashi N. et al. (1985) Photodegradation of the pyrethroid insecticide cypermethrin in water and on soil surface (Publication)
The photolytic degradation of cis- and trans isomers of cypermethrin was investigated in water. The samples were exposed to natural sunlight. Rapid degradation was observed in distilled water which could be enhanced further with acetone. Multiple degradation compounds could be identified. No guideline applied.

2. Takahashi N. et al. (1985) Hydrolysis of the pyrethroid insecticide cypermethrin in aqueous media (Publication)
Mechanistic investigation into the hydrolysis of cis- and trans isomers of cypermethrin under different pH values. The cleavage of the ester bond is faster than the hydration of the CN-group.
At pH lower than 7 cypermethrin is stable in sterile water whereas the hydrolytic degradation increases with higher pH values. No guideline applied.

3. Day S. R. et al. (1980) 14C Cypermethrin: Aqueous photodegradation in sunlight
Cypermethrin in sterile water solutions containing acetonitrile as co-solvent were exposed to natural sunlight (outdoor conditions) for 32 days. Only 10% degradation was observed at the end of the study. Dark controls showed no significant degradation. No guidelines applied.

CA 7.2.1.1 Hydrolytic degradation

Two hydrolysis studies performed with alpha-cypermethrin were submitted and evaluated previously.

Salisbury K., Weaver R. C. and Lagner E.J. 1984
The hydrolysis of FASTAC (WL85871)
BASF Doc ID: AL-322-001
GLP: no

Summary

The hydrolysis of alpha-cypermethrin at pH 5, 7 and 9 has been measured in aqueous buffer solutions containing 1% acetone. The experiments were conducted at elevated temperatures:
pH 5 at 60, 70 and 80°C, pH 7 and pH 9 at 50, 60 and 70°C. The sampling time was adjusted to the differing rate of degradation, but for at least 7 sampling points. Calculation of the degradation half- life was performed by linear regression ln Co/Ct versus time and recalculated for 22°C by using the Arrhenius equation. Half-lives at 22°C were 162 days, 46 days and 2.9 hour at pH 5, pH 7 and pH 9 respectively. The main degradation products (which were not quantified) were PBA and DCVA.
In a second experiment the epimerization of alpha-cypermethrin was investigated at ambient temperature at pH 9. Complete epimerization was found in 30 minutes. At elevated temperature and lower pH tome for epimerization increased, but was in any case faster than hydrolytic cleavage of the molecule.

Van Dijk A. 1993
Hydrolysis determination of 14C Alpha-cypermethrin at different pH values
BASF Doc ID: AL-322-002
GLP yes

Summary

In the present study, the rate (DT50) of hydrolysis of alpha-cypermethrin was determined in aqueous buffer solutions at pH 4, 7, and 9 at 25°C. Alpha-cypermethrin was incubated under sterile conditions and nitrogen at a concentration of 0.020 – 0.021 µg mL-1 at pH 4 and 7 and temperatures of ~~30~~ 50°C (both pH values), 60°C, and 75°C (only pH 7). At pH 9, 14C-alpha-cypermethrin was incubated at a concentration of 0.0011 µg mL-1 at 25°C and 50°C.
Except for one outlier (89.5% of the total applied radioactivity (TAR)), radioactivity was completely recovered in the organic phase, ranging from 96.2 to 100.0% TAR.
In the aqueous solution at pH4, exclusively the parent compound was found until 10 days of incubation at 50°C, indicating that alpha-cypermethrin was stable against hydrolysis at acidic pH.
At pH 7, alpha-cypermethrin was hydrolyzed with half-lives of 5.3 and 2.0 days at 60°C and 75°C, respectively. At pH 9, alpha-cypermethrin was hydrolyzed with half-lives of 3.5 and 3.0 hours at 25°C and 50°C, respectively.
Besides the parent compound, almost exclusively the hydrolysis product 3-PBAld occurred throughout all incubations. At pH 7, 3-PBAld was detected in maximum amounts of 21.6% (50°C), 71.7% (60°C), and 61.5% (75°C). At pH 9, maximum 88.4% (25°C) and 92.1% TAR (50°C) were measured. A more polar and unknown hydrolysis product occurred only in small amounts below 10% TAR at pH 7 and below 5% TAR at pH 9.
In conclusion, after applying data analyses via the Arrhenius equation at pH 7, half-lives of 101 and 67 days were calculated at 20°C and 25°C for alpha-cypermethrin, respectively. At pH 9 the corresponding half-lives of alpha-cypermethrin were 7.3 and 3.5 days, respectively.

To support the studies two additional hydrolysis studies were conducted and are submitted under CA 7.2.1.1/1 and CA 7.2.1.1/2.

Report: CA 7.2.1.1/1
Hassink J., 2005a
Hydrolysis of Alpha-Cypermethrin (TGAI batch COD-000165)
2005/1016375
Guidelines: EPA 161-1, SETAC Procedures for assessing the environmental fate and ecotoxicity for pesticides (March 1995), EEC 94/37, EEC 91/414
GLP: yes
(certified by Landesamt fuer Umweltschutz und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

A hydrolysis study was conducted for technical alpha-cypermethrin, TGAI batch COD-000165. Therefore, the test item was incubated in sterile buffer solution at 25°C over a study period of 30 days at pH 4, 5, 7 and 9. The study was designed to investigate the degradation rate of the test item in aqueous solutions to meet the requirements of both the EU and EPA guidelines.

The test item is stable in acidic media (pH 4), but the decline at pH 5 to 70% of the initial applied test item after 30 days and at pH 7 to 66% after 30 days indicate slow hydrolysis of alpha-cypermethrin with increasing pH. At pH 9 a significant decline to 66% of the initial applied test item after one day and to 10% after 16 days confirm the rapid hydrolysis of alpha-cypermethrin under alkaline conditions (DT50 pH: 2.9 h [SALISBURY, WEAVER, LANGNER (1984): THE HYDROLYSIS OF FASTAC (WL85871), BASF DocID AL-322-001]).

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Test item: alpha-cypermethrin
Reg. No.: 4078193
Batch No.: COD-000165 (TGAI)
Chemical name (IUPAC): racemate of (S)-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S)-isomer
Purity: 98.8%
Molecular weight: 832.60 g mol-1 (2 x 416.30 g mol-1)
Molecular formula: 2 C22H19Cl2NO3

2. Test system

All buffer solutions were prepared with commercially available buffers (Titrisol, Merck, Darmstadt, Germany) according to the manufacturer's instructions. Thereafter, the solutions were diluted by the factor 10 to avoid interactions with the test item. The following buffer solutions were used:

pH 4: Titrisol 1.09884 (citrate – HCl)
pH 5: Titrisol 1.09885 (citrate – NaOH)
pH 7: Titrisol 1.09887 (phosphate)
pH 9: Titrisol 1.09889 (boric acid/KCl – NaOH)

B. STUDY DESIGN

1. Experimental conditions

To test the hydrolysis at different pH values, different volumes of an application solution, containing 0.5 µg mL-1 of the test item dissolved in methanol/water (50/50, v/v), were pipetted into 500 mL of the respective sterilized buffer. 0.35 mL (pH 4 and 5), 2.00 mL (pH 7), and 2.25 mL (pH 9) were diluted in the respective buffer solution reaching a nominal concentration of 0.35 (pH 4 and 5), 2.00 (pH 7), and 2.25 µg L-1 (pH 9), respectively.

Subsets of 50 mL were used for each hydrolysis experiment. The sterile samples were stored in a climatic chamber at the required temperature of 25°C for 30 days. Sterility of the solutions was checked at each sampling time for the respective sample prior to analysis. The pH was checked for each sample after analysis.

2. Sampling

The sampling was performed 0, 1, 2, 7, 10, 16, 21 and 30 days after treatment.

3. Description of analytical procedures

Samples were extracted three times with 30 mL ethyl acetate. The extracts were combined and evaporated to dryness. The residue was dissolved in 50 mL methanol/water (50/50, v/v) and subsets of 20 µL were analyzed by high performance liquid chromatography/tandem mass spectrometry (HPLC-MS/MS).

II. RESULTS AND DISCUSSION

A. FINDINGS

Recoveries of 92-104% (pH 4), 70-111% (pH 5), 66-104% (pH 7), and 6-66% (pH 9) of the initial applied amount of the test item were obtained in the test systems during the testing period of 30 days. The decline at pH 5 to 70% after 30 days and at pH 7 to 66% after 30 days indicate slow hydrolysis of alpha-cypermethrin with increasing pH. Rapid hydrolysis occurred under alkaline conditions, i.e. only 66% of the initial applied amount was present after one day, about 10% were detected in the test system after 16 days. Results are given in Table 7.2.1.1-1.

Table 7.2.1.1-1: Hydrolysis of alpha-cypermethrin (TGAI batch COD-000165) at pH 4-9 and 25°C

** outlier, result not plausible

B. ESTIMATION OF HALF-LIVES

No estimation of half-lives was done since the results on the hydrolysis of technical alpha-cypermethrin confirm the pH dependency determined previously with the pure test item (DT50 pH 9: 2.9 h [BASF DocID AL-322-001].

III. CONCLUSION

Technical alpha-cypermethrin (TGAI batch COD-000165) is stable in acidic media (pH 4), but the rate of hydrolysis increases with increasing pH. At pH 9 a significant decline to 66% of the initial applied amount of test item after one day and to 10% after 16 days confirm the rapid hydrolysis of alpha-cypermethrin under alkaline conditions (DT50 pH 9: 2.9 h [BASF DocID AL-322-001]).

B. ESTIMATION OF HALF-LIVES

No estimation of half-lives was done since the results on the hydrolysis of technical alpha-cypermethrin confirm the pH dependency determined previously with the pure test item (DT50 pH 5: 162 d; DT50 pH 7: 46 d, DT50 pH 9: 2.9 h [BASF Doc ID AL-322-001].

III. CONCLUSION

Technical alpha-cypermethrin (TGAI batch COD-000166) is stable in acidic media (pH 4), but the rate of hydrolysis increases with increasing pH. At pH 9 a significant decline to 66% of the initial applied amount of test item after one day and to 1-3% after 16 days confirm the rapid hydrolysis of alpha-cypermethrin under alkaline conditions (DT50 pH 9: 2.9 h [BASF Doc ID AL-322-001]).

The RMS BE has asked for additional kinetic evaluations on 27. Oct. 2016. The results are presented and discussed below.

Report:	CA 7.2.1.1/3 Anonymous, 2016 a Response to RMS BE - Request concerning kinetic re-evaluations – Alpha-cypermethrin 2016/1324158
Guidelines:	none
GLP:	no

Hydrolysis study by Van Dijk (1993), BASF DocID: AL-322-002

RMS: The Notifier is requested to perform a comprehensive kinetic assessment according to FOCUS of the hydrolysis study by Van Dijk, 1993.

BASF response: A kinetic evaluation was performed according to FOCUS kinetics guidance document (2006) for the data from Van Dijk (1993). Only the SFO model was applied for the evaluation. The results are summarized in Table 7.2.2.1-3 and the corresponding Kingui fits are presented in Appendix 5 in the original response document. The trigger endpoints (DT_{50}: 28.7, 5.7 and 2.2 d for 50, 60 and 75°C at pH 7; DT_{50}: 3.3 and 0.1 d for 25 and 50°C at pH 9) are comparable to those derived in the original study (DT_{50}: 27.0, 5.3 and 2.0 d for 50, 60 and 75°C at pH 7; DT_{50}: 3.5 and 0.1 d for 25 and 50°C at pH 9). For this reason and taking into account that kinetic evaluation according to FOCUS is not formally required for hydrolysis studies, the endpoints of the original study are considered still valid.

Remark: In the dossier summary erroneously an incubation temperature of 30°C for pH 5 and 7 was reported. The correct incubation temperature was 50°C.

Table 7.2.1.1-3: Statistical and visual assessment of kinetic models for hydrolysis of alpha-cypermethrin under different pH and temperatures

pH	Temperature [°C]	Kinetic model	χ^2 [%]	p (t-test)	Visual assessment	$DegT_{50}$ [d]	$DegT_{90}$ [d]

Alpha-cypermethrin (FASTAC): Photodegradation in water (preliminary experiment) including a comparison with esfenvalerate
BASF Doc ID: AL-630-009
GLP yes

Summary
Unlabeled alpha-cypermethrin was dissolved in aqueous buffer solution and exposed to artificial sunlight. The study was not performed to guidelines nor has reliable results.

Concha M., Zhixing Y. and Beigel C. 2001
BAS 310 I (Alpha-cypermethrin): Aqueous photolysis
BASF Doc ID: AL-324-003
GLP: yes

Summary
In the present study, [benzyl-14C-] and [cyclopropane-14C-] alpha-cypermethrin were exposed to artificial sunlight in sterile aqueous pH 5 buffer solution at 0.002 ppm and 22°C for up to 15 and 28 days. Volatiles were trapped in ethylene glycol and two 10% KOH solutions. Samples were extracted after acidification (conc. HCl) with ethyl acetate and analyzed by liquid scintillation counting (LSC) and high performance liquid chromatography (HPLC).
The mass balances ranged from 90.0 to 113.2% of the total applied radioactivity (TAR) for the irradiated samples.
14C-alpha-cypermethrin degraded rapidly in the light exposed samples and represented 52.5% and 33.6% TAR in the benzyl- and cyclopropane-labeled samples, respectively, after 2 days of exposure. By the end, detected 14C-alpha-cypermethrin amounts decreased below the detection limit (both labels).
Main metabolites with the benzyl-labeled test item were 3-PBAld (maximum 15.9% TAR at day 2) and 3-PBA (maximum 22.5% TAR at day 4), both decreasing towards the end of the study period. Unextracted radioactivity increased to 26% TAR at the end of the study. Several other more polar metabolites occurred only in small amounts below 8% TAR. 21.4% TAR were mineralized, less than 3% TAR was recovered in the traps for organic volatiles at study end.
The main metabolites observed with the cyclopropane-labeled test item was CL 901649 (mixture of cis and trans), which reached a maximum of 43.7% TAR at day 8, declining to 34.8% TAR by day 28. Unextracted radioactivity amounted to maximum 34.8% TAR at day 8, decreasing to 10.3% TAR by the end of the study. Another metabolite (CL 1500788) was detected in maximum amounts of 11.4% TAR in one replicate of day 8, but was detected only in small amounts in the other replicate. In day 15 and day 28 samples, amounts were below the detection limit. 7.7% TAR were mineralized by the end of the study, 1.0% TAR was recovered in the traps for organic volatiles.
Alpha-cypermethrin did not degrade significantly in the dark control samples; therefore, degradation of alpha-cypermethrin in the irradiated samples can be attributed to photochemical reactions.

Calculated first-order DT50 and DT90 values of alpha-cypermethrin were 2.2 and 7.3 days, (benzyl label), respectively, and 1.2 and 4.1 days (cyclopropane label), respectively. Based on 8.4 hours of artificial light irradiation (1 solar day), DT50 and DT90 values of alpha-cypermethrin were 6.3 and 20.9 days, (benzyl label), respectively, and 3.4 and 11.7 days (cyclopropane label), respectively.

CA 7.2.1.3 Indirect photochemical degradation

Stone C.M. and Watkinson R.J. 1983
WL85871: An assessment of ready biodegradability
BASF DocID: AL-690-001
GLP: yes

Summary
Alpha-cypermethrin was tested for ready biodegradability in 3 tests, a "Closed Bottle", a "Modified Sturm Test" and a growth inhibition test with Pseudomonas fluorescens. In the closed bottle test, no oxygen depletion could be observed after 28 days. In the modified Sturm Test no CO2 was evolved after 28 days. The growth of Pseudomonas fluorescens was not inhibited.
Conclusion: Alpha-cypermethrin is not ready biodegradable.

No further tests were performed as higher tier studies are available.

14C-Alphacypermethrin (BAS 310 I): Aerobic Mineralisation in Surface Water
2014/1031017
Guidelines: OECD Guideline 309
GLP: yes
(certified by the Department of Health of the Government of the United Kingdom, United Kingdom)

Executive Summary

The purpose of this study was to determine the mineralization and degradation rates of the pyrethroid insecticide alpha-cypermethrin (BAS 310 I) in an aquatic system under dark conditions. The study was performed according to OECD guideline 309 (Aerobic mineralization in surface water – Simulation biodegradation test). The pelagic test system was chosen for this study.

The test was performed at concentration levels of 0.5 µg L-1 alpha-cypermethrin (low concentration) and 3.5 µg L-1 (high concentration), using two differently 14C-labeled test items (cyclopropyl and benzyl label). Sterilized samples were tested for each label of the higher concentration. The test vessels were attached to a flow-through system for continuous aeration and incubated at a temperature of 20 ± 2°C in the dark. Samples for the experiment were taken at 0, 1, 3, 7, 14, 22, 35 and 59 days after treatment.

After adding formic acid to the water samples, liquid/liquid partition extraction was performed using dichloromethane (DCM). The amount and nature of radioactivity in DCM layers and selected aqueous phases (phase remaining after DCM partition) was determined by liquid scintillation counting (LSC) and high performance liquid chromatography (HPLC), as well as thin layer chromatography (TLC), both coupled with radioactivity detection. Volatiles were trapped in 2M sodium hydroxide and also analyzed by LSC.

Selected samples were analyzed by chiral HPLC to investigate the individual degradation behavior of the two isomers forming alpha-cypermethrin, a racemate of the two cis-2 isomers present in cypermethrin (a racemic mixture of a total of eight isomers). At all times after 0 DAT, approximately equal levels of the two cis-1 and cis-2 isomers were detected. This shows that isomerization of cis-2 to cis-1 isomers occurred and that the four isomers appeared to be in equilibrium.

The cyclopropyl and benzyl labeled test items were significantly degraded in the natural water environment provided in this test. After 59 days, 2.3 to 11.4% TAR was recovered as unchanged active substance in viable units and 5.5 to 12.1% TAR in sterilized units. There was extensive mineralization of the benzyl ring system (34 - 39% TAR) and lower mineralization in the cyclopropyl ring system (4 - 11% TAR) in viable units but ≤ 1% TAR in sterilized units. Degradation was therefore biotic and abiotic and different routes of degradation were followed.

After treatment with [cyclopropyl-14C] alpha-cypermethrin, material balance at 0 DAT and 59 DAT ranged from 93.7 to 98.1% TAR for the mean of the two replicates in the viable test vessels, and 94.3 to 98.6% TAR for the sterilized vessels. Corresponding values obtained after treatment with [benzyl-14C] alpha-cypermethrin were 82.5 and 100.6% TAR for the viable test vessels and 86.1 and 94.8% TAR for the sterilized vessels. Recovery of radioactivity at sampling times between 0 and 59 DAT decreased to < 90% on several occasions and this was attributed to problems with the analysis caused by the occurrence of biofilm.

Biofilms formed during the incubation and adsorbed radioactivity from the solutions causing problems with mass balance. Although extra radioactivity was extracted from biofilm for some samples, not all samples had mass balance values > 90%.

Major metabolites in viable test units were 3-phenoxybenzoic acid (3-PBA), dichlorovinylcarboxylic acid (DCVA) and carbon dioxide. Maximum levels of 3-PBA (mean of two replicates) were 56.1% (benzyl label), maximum levels of DCVA were 77.7% (cyclopropyl label) and maximum levels of carbon dioxide were 37.6% (benzyl label). 3-Phenoxybenzaldehyde (3-PBAld) was detected in sterilized systems but not in non-sterilized systems (maximum levels were 8.5%, benzyl label). DCVA did not degrade during the study, but 3-PBA reached a maximum after 35 days and then slightly decreased again. 3-PBAld reached a maximum of 8.5% TAR at 14 DAT in the sterilized system and then decreased to < 1% TAR at 59 DAT. One unidentified degradation product (Unk 309-1) was present after 3 days at a maximum of 5.6% TAR in the cyclopropyl label low application rate group and decreased again. Since it exceeded 5% TAR only at one single sampling interval, it was not further identified.

Kinetic analysis and calculations of DegT50 and DegT90 values were performed following the recommendations of the FOCUS Kinetics workgroup on derivation of aquatic persistence endpoints. The analysis was done by a non-linear regression method (IRLS) using the software package KinGUI2. The evaluation of the results for high and low test concentrations for both labels showed that degradation of alpha-cypermethrin in the test systems was best described by DFOP kinetics and reliable degradation endpoints could be derived from all test systems ranging from 2.3 to 3.4 days (DegT50) and from 36.5 to 86.8 days (DegT90). For the metabolite DCVA, no reliable endpoints could be derived from any of the test systems treated with the cyclopropyl-labeled alpha-cypermethrin while for the metabolite 3-PBA reliable endpoints could be derived from the test system with benzyl-labeled alpha-cypermethrin applied at the high dose with 45.2 days and 150.2 days for DegT50 and DegT90, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

BAS-Code: BAS 310 I (alpha-cypermethrin)
Chemical name: Racemate of (S)-cyano-3-phenoxybenzyl (1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-cyano-3-phenoxybenzyl (1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate
Molecular formula: C22H19Cl2NO3
Molar mass: 416.3 g mol-1 (unlabeled)

Label 1 (cyclopropane label)
Label: cyclopropane-1-14C
Batch No.: 986-2101
Specific radioactivity: 4.71 MBq mg-1
Radiochemical purity: 96.9%
Chemical purity: 91.8%

Label 2 (benzyl label)
Label: benzylring-U-14C
Batch No.: 775-0601
Specific radioactivity: 4.74 MBq mg-1
Radiochemical purity: 99.5%
Chemical purity: 96.1%

2. Test system

Water and small amounts of sediment were collected from The Lake at Studley Royal (Ripon, United Kingdom). The physico-chemical properties of the system are summarized in Table 7.2.2.2-1.

Prior to use the sediment and water were stored together in the dark at 4 ± 2°C with free access to air. Water was filtered through a 0.1 mm sieve and sediment was passed through a 2 mm sieve.

Table 7.2.2.2-1: Characterization of the water/sediment system

Organic carbon	[%]	4.0	

B. STUDY DESIGN

1. Experimental conditions

A total of 104 test vessels was prepared: 20 test vessels for each radiolabel (cyclopropyl and benzyl) and each nominal concentration (0.5 and 3.5 µg L-1), 10 vessels for the sterile incubation (both labels; 3.5 µg L-1), 2 vessels as system control with sodium [14C]-benzoate and 2 vessels with sodium [14C]-benzoate plus treatment solvent. The vessels were filled with about 100 mL water. Appropriate amounts of the respective application solutions were pipetted dropwise to the water surface to achieve a nominal application rate of 0.5 µg L-1 or 3.5 µg L-1, respectively.

The systems were incubated at 20 ± 2°C in a metabolism apparatus (incubator) with a flow system providing a continuous flow of fresh air. Each test vessel was connected to a set of volatile traps. The first volatile trap was empty to act as a security trap and the following two traps contained trapping solutions (2x NaOH) for the 14C-volatiles to be expected. Test vessels containing sterile water were also aerated, however, the air stream was led through sterile filters to avoid contamination of the test system by airborne germs.

2. Sampling

Samples, including the sterile groups, were taken at 0, 1, 3, 7, 14, 22, 35 and 59 days after treatment (DAT). For sampling, the flasks were removed from the rigs and the temperature, O2 content, pH, and redox potential of the water was measured in a representative treated sample.

3. Description of analytical procedures

Water
Formic acid was added to each sample. Liquid-liquid partition extraction was performed using dichloromethane (DCM). The radioactivity in DCM layer as well as the water phase was measured by liquid scintillation counting (LSC). After evaporation and reconstitution in acetonitrile, aliquots of the DCM extracts were analyzed by high performance liquid chromatography (HPLC; higher application rate) and TLC (low application rate). Selected samples were analyzed by chiral HPLC to investigate the individual degradation behavior of the two isomers forming alpha-cypermethrin.

Recovery of radioactivity using the method described above was variable and sometimes lower than 90%. Two possibilities were investigated to account for the loss. The first was that radioactivity could be associated with a biofilm that was visible on the incubation vessels after washing with DCM and was present in the DCM phases as precipitates or floating debris. The second was that radioactivity was present as dissolved carbon dioxide that was lost during the acidification and partitioning process.

After washing the incubation vessels with DCM as described for the original method, acetone was added to each empty test vessel and sonicated. Radioactivity was determined by LSC. This procedure was performed at 14 DAT (except controls), and later times, but could not be performed at earlier times because the original incubation vessels were no longer available.

Volatiles
After collecting the traps attached to each test vessel being sampled (all, except the control vessels), formic acid was added and the units were re-attached to the incubation system with fresh 2M sodium hydroxide traps. Air was bubbled through each acidified unit. The units were stirred during the process. After 1 hour, any radioactivity recovered in the sodium hydroxide traps was determined by LSC. This procedure was used on units at 22 DAT onwards (except at 35 and 59 DAT), and it was limited to units treated with the benzyl label.

4. Calculation of the degradation/dissipation rates

Kinetic evaluation was performed in order to derive aquatic persistence endpoints. The kinetic analysis was carried out following the recommendations of the FOCUS work group on degradation kinetics [FOCUS (2006): “Guidance Document on Estimating Persistence and Degradation Kinetics from Environmental Fate Studies on Pesticides in EU Registration” Report of the FOCUS Work Group on Degradation Kinetics, EC Document Reference Sanco/10058/2005 version 1.0 (November 2011), 436pp.] in order to derive persistence endpoints.

The software package KinGUII (version 2.2014.224.1704) was used for parameter fitting [SCHÄFER, D., MIKOLASCH, M., RAINBIRD, P., HARVEY, B. (2007) KinGUI: A new kinetic software tool for evaluations according to FOCUS Degradation Kinetics. In: Del Re, A.A.M. et al. (Eds.): Proceedings of the XIII Symposium on Pesticide Chemistry, Piacenza, 2007, p. 916-923., WITT, J., GAO, Z., MEYER, H. (2014) KinGUII, Version 2.2014.224.1704 Bayer CropScience AG]. The error tolerance and the number of iterations of the optimization tool were set to 0.00001 and 100, respectively.

For each data set, the kinetic models proposed by the FOCUS Kinetics guidance document were tested in order to identify the best-fit model. The recommended kinetic models, i.e. the single first order kinetics (SFO), the Gustafson-Holden model (FOMC), and bi-exponential (DFOP) kinetics are already implemented in KinGUI. The Goodness-of-fit was evaluated by visual assessment, $\chi 2$ minimum error, and type-I-error rate (t-test) [for details see Chapter 6.3 in FOCUS (2006)].

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The distribution of radioactivity in the different extracts of the water system treated with 14C-alpha-cypermethrin (cyclopropyl and benzyl label) is presented in Table 7.2.2.2-2 and Table 7.2.2.2-3.

The applied mass of test item per test vessel containing 100 mL of water was 0.34 µg (high concentration) and 0.05 µg (low concentration).

The material balance for the pelagic test ranged from 82.8 – 100.8% of the total applied radioactivity (TAR) in Lake water treated with the cyclopropyl-14C-labeled test item and from 82.5 – 100.6% TAR in Lake water treated with the benzyl-14C-labeled test item. In the sterile vessels, the material balance ranged from 90.5 to 98.6 TAR (cyclopropyl label) and from 84.0 to 95.4% TAR (benzyl label), respectively.

Recovery of radioactivity at sampling times between 0 and 59 days after treatment (DAT) decreased to < 90% on several occasions. Low mass balance results generally occurred when high levels of radioactivity were associated with biofilm.

Mineralization of alpha-cypermethrin to CO2 occurred from the benzene ring system (up to 37.6% TAR) and to a much lesser extent from the cyclopropyl ring system (up to 10.9% TAR). Carbon dioxide was identified by complete precipitation of the radioactivity from trapping solutions after adding barium chloride solution to selected samples.

B. TRANSFORMATION OF PARENT COMPOUND

Characterization and identification of residues in water extracts

Water
Cypermethrin (no separation into individual isomers) and its metabolites (DCVA, 3-PBA, 3-PBAld) from the high and low application rate groups were identified by HPLC and by TLC, respectively. The summary of radio-TLC and radio-HPLC analysis of the water phases (DCM extracts) and selected aqueous phases (phase remaining after DCM partition) is presented in Table 7.2.2.2-4 to Table 7.2.2.2-7.

Significant degradation of cypermethrin occurred forming DCVA, 3-PBA and 3-PBAld (sterilized lake water only).

DCVA was a major metabolite produced from the cyclopropane ring system. The metabolite generally increased throughout the incubation period comprising 74.1 to 77.7% TAR at 59 DAT. The metabolite also increased in the sterilized incubation group reaching a similar level at 59 DAT (77.5% TAR).

3-PBA was a major metabolite produced from the benzene ring system. The metabolite was present at up to 56.1% TAR (35 DAT). It did not continuously increase during the incubation period. It was present at generally higher levels in the sterilized test system (maximum 69.8% at 22 DAT). In viable incubation groups at the end of the test (59 DAT), levels were 31.5 to 32.5% TAR but in the sterilized incubation group levels were 64.8% TAR.

3-PBAld was only a major metabolite from the benzene ring system in sterilized lake water. Levels increased to 8.5% TAR at 14 DAT before decreasing to < 1% TAR by 59 DAT.

An unidentified metabolite (Unk 309-1) was present at up to 5.6% TAR in the cyclopropyl label low application rate group and at lesser concentrations in other treatment groups. Since it exceeded 5% TAR only at one single sampling interval, it was regarded as non-relevant and it was not further characterized. There were no other metabolites detected that were present at > 10% TAR at any time or that were present at ≥ 5% TAR at two consecutive sampling intervals.

Concentration of samples for chromatography resulted in occasional large losses of radioactivity because some of the biofilm re-precipitated from extracts used for chromatography, removing some of the radioactivity with it. A check was made that the radioactivity lost from solution was equivalent in nature to the radioactivity remaining in solution.

Sterilized samples

The main difference between results from sterilized incubation groups and viable incubation groups was that there was ≤ 1% TAR mineralized in sterile groups but up to 37.6% mineralized from viable groups. Mineralization can therefore be considered to be a biotic process. Hydrolysis occurred in the sterilized system and therefore the pH of the water was favorable for hydrolysis. DCVA formed under abiotic processes (i.e. hydrolysis) but did not mineralize in the viable samples.

The other differences concerned the metabolites present in the water. Hydrolysis to 3-PBAld was only detected in sterilized samples. In viable samples the metabolite was not detected and the hydrolysis proceeded through to 3-PBA. It can be concluded that 3-PBAld is not stable under biotic conditions.

3-PBA was present at generally higher levels in sterilized samples compared to viable samples. It is concluded that 3-PBA was the precursor to mineralization.

Enantiomer specific analysis

In addition to the quantification of the parent, enantiomer-specific analyses were performed by radio-HPLC. The amounts of each cis-1 and cis-2 isomer present in the DCM extracts of water from non-sterilized and sterilized incubation groups for each label are shown in Table 7.2.2.2-8 and Table 7.2.2.2-9.

In all incubation groups, the cis-2 isomers of alpha-cypermethrin formed cis-1 isomers within three days after treatment. After this time all four cis isomers of cypermethrin decreased at the same rate and each isomer comprised a similar proportion of the total radioactivity present.

The isomerization occurred in the sterilized samples to the same extent as in the non-sterilized samples and therefore it was assumed to be a chemical rather than a microbial process.

Control samples
Recovery of radioactivity from the reference vessels at the end of the test was 96.5% for units treated with sodium [14C]-benzoate alone and 96.6% for units treated with sodium [14C]-benzoate and acetonitrile.

Sodium benzoate extensively mineralized to CO2 with 83.5% to 86.2% mineralization at 14 DAT and 93.2 to 94.5% mineralization at 59 DAT. The system was therefore viable. The control vessels treated with [14C]-sodium benzoate showed that the test system was microbially active both without and with the addition of acetonitrile. The total recoveries of trapped volatile radioactivity after 59 days were 94.5 and 93.2% TAR and the material balances were 96.5 and 96.6% TAR for the samples without and with acetonitrile, respectively.

The reason why mass balance was not obtained is probably related to adsorption to or incorporation into biofilm. Similar difficulties were experienced in obtaining mass balance results from units treated with alpha-cypermethrin. At 0 DAT (samples treated with acetonitrile) the mass balance was 100.3% showing that there was no error on application or sampling technique. The mass balance results of 96.5% and 96.6% at the end of the 59 day incubation also show that there was no error on application.

Degradation rates

The degradation of alpha-cypermethrin was evaluated according to the recommendations of the FOCUS workgroup on degradation kinetics [FOCUS (2006)]. A summary of the DegT50 and DegT90 values of alpha-cypermethrin and its metabolites DCVA and 3-PBA derived as persistence endpoints are given in Table 7.2.2.2-10 and Table 7.2.2.2-11.

The evaluation of the results for high and low test concentrations for both labels showed that degradation of alpha-cypermethrin in the test systems was best described by DFOP kinetics and reliable degradation endpoints could be derived from all test systems. For the metabolite DCVA, no reliable endpoints could be derived from any of the test systems treated with the cyclopropyl-labeled alpha-cypermethrin while for the metabolite 3-PBA reliable endpoints could be derived from the test system with benzyl-labeled alpha-cypermethrin applied at the high dose. As 3-PBAld was only present in sterilized samples but not in viable samples, no reliable endpoints could be derived.

Table 7.2.2.2-9 Summary of the kinetic evaluation of alpha-cypermethrin

Test system	Kinetic model	χ^2 error	Best-fit endpoints	
			$DegT_{50}$ [d]	$DegT_{90}$ [d]
Low test concentration, cyclopropyl label	DFOP	9.9	3.1	43.0
Low test concentration, benzyl label	DFOP	9.8	2.3	86.8
High test concentration, cyclopropyl label	DFOP	9.5	3.4	36.5
High test concentration, benzyl label	DFOP	6.5	3.3	36.8

Table 7.2.2.2-10: Summary of the kinetic evaluation of alpha-cypermethrin metabolites DCVA and 3-PBA

Test system	Compound	Kinetic model	χ^2 error	Best-fit endpoints	
				$DegT_{50}$ [d]	$DegT_{90}$ [d]

[a] DFOP kinetics for parent

III. CONCLUSION

Alpha-cypermethrin was significantly degraded in the natural water environment provided in this test. After 59 days, only 2.3 to 11.4% TAR of unchanged parent remained. There was significant mineralization of the benzyl ring system (34 - 39% TAR) and less mineralization of the cyclopropyl ring system (4 - 11% TAR). Two major metabolites were formed, DCVA (maximum 77.7% TAR at 59 DAT) and 3-PBA (56.1% TAR at 35 DAT). Furthermore, 3-PBAld was present in sterilized samples (maximum 8.5% TAR at 14 DAT) but not in viable samples which indicates that it is not stable under biotic conditions. An unidentified compound was present at up to 5.6% TAR (3 DAT) but it occurred only on single sampling events and was therefore not further identified. There were no other compounds present at ≥ 10% TAR or ≥ 5% TAR at two consecutive sampling times.

In all incubation groups, the cis-2 isomers of alpha-cypermethrin formed cis-1 isomers within 3 DAT. After this time all four cis isomers of cypermethrin decreased at the same rate and each isomer comprised a similar proportion of the total radioactivity present. The isomerization occurred in the sterilized samples to the same extent as in the non-sterilized samples and therefore it was assumed to be a chemical rather than a microbial process.

The evaluation of the results for high and low test concentrations for both labels showed that degradation of alpha-cypermethrin in the test systems was best described by DFOP kinetics and reliable degradation endpoints could be derived from all test systems ranging from 2.3 to 3.4 days (DegT50) and from 36.5 to 86.8 days (DegT90). For the metabolite DCVA, no reliable endpoints could be derived from any of the test systems treated with the cyclopropyl-labelled alpha-cypermethrin while for the metabolite 3-PBA reliable endpoints could be derived from the test system with benzyl-labeled alpha-cypermethrin applied at the high dose with 45.2 days and 150.2 days for DegT50 and DegT90, respectively.

The RMS BE has asked for additional kinetic evaluations on 07. Dec. 2016. The results are presented and discussed below.

Report:	CA 7.2.2.2/2 Anonmyous, 2016 a Response to RMS BE. Request concerning kinetic re-evaluation of Lewis 2014a – Alpha-Cypermethrin 2016/1344967
Guidelines:	none
GLP:	no

RMS: RMS notes that the Notifier performed a separate kinetic assessment for each label. In peer review, it is common practice to handle residuals from the same soil with different radiolabelled positions as replicate values. Please Notifier consider that residue data from two tested labels from the same soil need to be processed as replicates for the active substance and its metabolites.

BASF response: A kinetic evaluation was performed for the parent substance by processing the residue data of the two tested labels as replicates. The results are summarized in Table 7.2.2.2-11 and Table 7.2.2.2-12 and the corresponding Kingui fits are presented in the Appendix of the original response document. The trigger endpoints (low test concentration: $DegT_{50}$ = 2.4 d, $DegT_{90}$ = 63.1 d, DFOP model, high test concentration: $DegT_{50}$ = 2.8 d, $DegT_{90}$ = 38.2 d, DFOP model) are comparable with those derived by performing a separate kinetic assessment for each label (low test concentration: geomean $DegT_{50}$ = 2.7 d, geomean $DegT_{90}$ = 61.1 d, high test concentration: geomean $DegT_{50}$ = 3.3 d, geomean $DegT_{90}$ = 36.6 d). Therefore, the endpoints presented in the dossier are considered adequate.

The metabolites are formed label-specific (DCVA from cyclopropyl-label, 3-PBA from benzyl-label). Therefore, an evaluation with the different labels handled as replicates cannot be performed for the metabolites.

CA 7.2.2.3 Water/sediment studies

Numerous studies were performed with cypermethrin or alpha-cypermethrin to address the behaviour in water /sediment systems. An overview can be found in Table 7.2.2.3-1. Sufficient data are available on alpha-cypermethrin, so that studies on cypermethrin can be disregarded for the assessment. The latest studies from Mamouni (1993) and Voelkl (1993) were re-evaluated according to FOCUS kinetics and are re-submitted and discussed here for reasons of completeness.

Table 7.2.2.3-1: List of water/sediment studies performed with (alpha-) cypermethrin

Studies performed with cypermethrin. Not used for assessment

1. Rapley J.H. et al. (1981): Cypermethrin: Degradation in river and pond waters and sediments
Three river and a pond water and the corresponding sediments were incubated with cypermethrin labelled in the cyclopropyl and the benzene ring for up to one year at 16°C. Some incubation vessels were aerated, other were left undisturbed. Redox potentials ranged from approximately
-200 mV to + 500 mV. Cypermethrin was rapidly degraded (50% in less than two weeks). The main degradation products were cis and trans DCVA, PBA and PBAld. PBA and PBAld were further degraded. The highest aldehyde concentration was detected in a system with low redox potential. For a kinetic evaluation of cypermethrin sampling intervals were too large.For this reason and because the study was performed with cypermethrin this study will not be included into the assessment. The studies of Mamouni (1993) and Völkl (1993) will be used.

2. Hadfield S.T. et al. (1993) Pyrethroid residues in sediment and water samples from mesocosm and farm pond studies of simulated accidental aquatic exposure (Publication)
No regulatory relevant trial design. Not considered.

Trials performed with alpha-cypermethrin not used for evaluation

1. Dutton A.J. et al. (1988): An outdoor tank experiment to study the fate of FASTAC in the aquatic environment
Alpha-cypermethrin labelled in the cyclopropyl and the benzyl ring was applied to outdoor tanks containing pond water and sediment. The systems were sampled up to 202 days and water and sediment were analysed for radioactivity and chromatographed to identify metabolites. Alpha-cypermethrin rapidly dissipated from the water within 2 to 4 days. The main metabolites formed were DCVA and PBA. The study was not performed according to a guideline and quantification is questionable as results were reported as percentage of extracted radioactivity. Due to the outdoor environment a balance could not be obtained.

2. Pearson N (1990): The fate of FASTAC in experimental ponds
Similar experimental set-up as Dutton (1988), more biological testing of sensitive species. The study was not performed according to a guideline and quantification is questionable as results were reported as parent equivalent in different water layers and sediment. Due to the outdoor environment a balance could not be obtained.

The studies of Mamouni and Voelkl were considered as best description of the behaviour of alpha-cypermethrin in water/sediment systems. As a new kinetic evaluation was performed, the studies are re-submitted and summarized in detail.

Executive Summary

The degradation of benzyl-14C-alpha-cypermethrin (FASTAC) in two aerobic water/sediment systems was investigated: the Rhine River and the Pond aquatic systems. Test vessels were treated with benzyl-14C labeled alpha-cypermethrin with a concentration corresponding to a field application rate of about 42 g a.s. ha-1 when assuming that the a.s. is homogeneously distributed in a natural water of 30 cm depth.

The test vessels were connected to an aeration system at a temperature of 20 ± 2°C in a dark room. Samples were taken directly after the treatment and 6 hours, 24 hours and 2, 7, 14, 30, 61 and 105 days after the application. Water and sediment extracts were analyzed by thin-layer-chromatography. The amount of non-extractable residues was determined by combustion and liquid scintillation counting (LSC). Volatiles were trapped in appropriate trapping solutions and also analyzed by LSC. Metabolite identification was done by co-chromatography with reference substances.

High mineralization was observed in both systems. 14CO2 amounted to 41.1% and 54.6% of the total applied radioactivity (TAR) in the Rhine and Pond system, respectively. No volatile radioactivity (< 0.1% TAR) was trapped in the ethylene glycol solutions of either system.

The disappearance of the parent compound from the water phase by hydrolysis and mineralization and adsorption to sediment was rapid in both systems, only 1.6% and 8.0% TAR remained in water after 7 days in the Rhine River and Pond aquatic systems, respectively.

Alpha-cypermethrin was degraded more rapidly in the Pond sediment than in the Rhine river sediment, because of the higher microbial activity in the Pond system. Five times as much radioactivity of the test item was present in the Rhine River sediment than in the Pond sediment after 30 days of incubation time. At the end of the incubation period, 12.9% and 2.0% TAR was present as parent compound in the Rhine and Pond sediments, respectively.

The test item was degraded to a minimum of ten radioactive fractions. M3 (WL 44607; 3-PBA) was the main radioactive fraction but was rapidly further degraded to CO2. Benzyl-14C-alpha-cypermethrin was degraded by hydrolysis at the ester bound linkage leading to the formation of WL 44607 (maximum amounts of 21.7% TAR and 23.1% TAR -referring to the whole system), which was further degraded to CO2. The remaining metabolites (all unknown except radioactive fraction M2, which was characterized as WL 46114) were found in very low amounts and did not exceed 7.9% TAR. The low amount of WL 46114 revealed that ring hydroxylation is a minor route of degradation of benzyl-14C-alpha-cypermethrin in sediment and indicates that the latter was further degraded by microorganisms.

Part of the radioactivity was converted into non-extractable residues amounting to 18.9% TAR (Rhine) and 21.2% TAR (Pond), respectively, at the end of the study.

Overall, the results of this study showed that benzyl-14C-alpha-cypermethrin was rapidly eliminated from both aquatic systems by rapid hydrolysis, microbial degradation, and mineralization.

A kinetic analysis of the data of the summarized study is presented in section CA 7.2.2.3/3 [SACHERS, S. (2014b): Kinetic evaluation of degradation of BAS 310 I - alpha-cypermethrin in water/sediment systems: Determination of trigger and modeling endpoints according to FOCUS, BASF DocID 2014/1159506].

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Internal code: BAS 310 I
Reg.No.: 4078193
CAS Number: 67375-30-8
Chemical name: 1:1 mixture of (S)-alpha-cyano-3-phenoxybenzyl-(1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-alpha-cyano-3-phenoxybenzyl-(1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethyl cyclopropanecarboxylate
Molecular formula: C22H19Cl2NO3
Molecular mass: 418.9 g mol-1
Label: benzyl-14C
Specific activity: 191.7 µCi mg-1
Radiochemical purity: >99% (checked by RCC using TLC in at least two different solvent systems)

2. Test system

Two different test systems were applied:

System I Rhine-river water + Rhine sediment (Rhine, Mumpf/Switzerland)
System II Pond water + Pond sediment (Pond, Rheinfelden [AG]/Switzerland)

The physico-chemical properties of the systems are summarized in Table 7.2.2.3-2.

Table 7.2.2.3-2:: Characterization of the water/sediment system

River and Pond water were analyzed for several pesticides (lindane, heptachlor, malation, DTT, Dieldrin, PCBs), none was detected.

B. STUDY DESIGN

1. Experimental conditions

The study was performed in an open gas-flow-system in 1000 mL all-glass metabolism flasks containing about 275 g and 190 g of sediment (to obtain a 2.5 cm sediment layer) for the Rhine and Pond aquatic systems, respectively, and 550 mL of water. These amounts were obtained by assuming a height of the water column of about 6 cm and a 2.5 cm thick sediment layer. The system was ventilated with moistened CO2-free air at a flow rate of about 60 mL min-1 with simultaneous gentle agitation of the water column by means of a suspended magnetic stirrer. The out coming air was passed through a trapping system of 2N NaOH (50 mL) and ethylene glycol (50 mL).

The test systems were acclimatized for about two weeks before application. The samples were incubated at 20 ± 2°C in a dark room (temperature controlled). During incubation, the water was gently stirred from the top without disturbing the sediments.

Aliquots of 400 µL containing 7.73 µg of benzyl-14C-alpha-cypermethrin were applied drop-wise to each flask. This corresponds to target concentration of 14 µg L-1 and a field application rate of about 42 g active substance ha-1 assuming that the test item is homogeneously distributed in the top 30 cm of the water column. Reserve as well as control flasks were included in the study.

The two untreated controls were used to determine the biomass at the end of the study.

2. Sampling

Water and sediment samples were taken in duplicates for analysis directly after the treatment and 6 hours, 24 hours and 2, 7, 14, 30, 61 and 105 days after the application. The reported results are thus, the means of both samples. The water was sampled down to a depth of 10-30 cm and the sediment was sampled from the top 5-10 cm of each system. This sampling site was located 1-2 m from firm land.

Volatile traps
Sodium hydroxide solutions were exchanged at each sampling interval and additionally on days 44, 72 and 89. Analyses of these solutions were performed accordingly. Ethylene glycol solutions were counted for after each sampling and replaced only at day 7, 44, 57, 72 and 89, due to the low amount of volatile substances detected so far (< 0.l% of the total applied radioactivity (TAR) on each sampling interval).

3. Analytical procedures

Water phase
After separation from sediment, the radioactivity in the water was determined directly by LSC. Thereafter, the water samples were partitioned with organic solvent at pH 4 using acetic acid, or otherwise stored deep-frozen at about -20°C until required for further analyses. For each sampling interval, about 300 mL water was partitioned one to three times with ethyl acetate (100 mL) (except samples after 6 hours of incubation chloroform was used). The extracts were combined then further concentrated in a Rotavap. The concentrates were submitted to TLC-analyses.

Sediment phase
The sediment samples were submitted to the following extractions:
1. - acetonitrile, one to three times (except on day 0, acetone was used 3 times).
2. - acetonitrile/water (7/3, v/v), once (on days 0.25, l, 2, 28 and 29)
   - acetonitrile/water/hydrochloric acid (50/50/1), on days 61 and 105
   - acetone, once (on days 14 and 30)
3. Soxhlet with methanol (from day 14 onward)
   The extracts mentioned above per sampling interval were combined and concentrated by evaporation of acetonitri1e and acetone in a Rotavap.

The residual radioactivity remaining in the sediment after all these extractions was then determined by combustion.

Characterization of bound residues
An additional fractionation of organic matter was carried out with the sediment residues after exhaustive extraction from interval 30 days. This fractionation was performed by extraction of the soil residues with 0.5 M NaOH solution. Thereafter, the humic acids were precipitated by decreasing the pH to about 1. Centrifugation permits separation of the fulvic acids which remain in the liquid phase. The humin fraction remains unextracted together with the clay mineral and aluminum oxides.

Volatiles
Radioactivity in the volatile trapping solutions was determined by LSC.

4. Kinetic modeling

The kinetic analysis was carried out according to previous requirements in the summarized study. A new kinetic analysis following the recommendations of the FOCUS work group on degradation kinetics [FOCUS (2006)] will be provided in section CA 7.2.2.3/3 [BASF DocID 2014/1159506].

II. RESULTS AND DISCUSSION

A. MASS BALANCE

The distribution of radioactivity to the different compartments of the water/sediment system treated with the test item is presented in Table 7.2.2.3-3 and Table 7.2.2.3-4, respectively.
Total mean recoveries were 90.1% TAR for the Rhine aquatic system and 91.9% TAR for the Pond river aquatic system, resulting from both phases, sediment and water, and volatile substances as described below (mean over all replicates).

The amount of radioactivity recovered from day 7 until the end of the study declined with time. This decrease is clearly attributed to loss of 14CO2 from the system, due to the high degree of total mineralization observed. (Additional experiments demonstrating the loss of 14CO2 during the acidification and partitioning of the water phase are described in the study report. Furthermore, loss of 14CO2 probably happened during measurement of pH, O2, and redox potential after sampling. The high amounts of 14CO2 loss neither influence the calculation of the degradation rate of benzyl-14C-alpha-cypermethrin nor the amounts of metabolites found.)

Water phase
The amount of radioactivity in the Rhine River water decreased rapidly from day 0 (49.9% TAR) to day 105 (1.9% TAR). Similarly, the radioactivity was rapidly eliminated from the Pond water decreasing from 61.2% TAR at day 0 to 0.9% TAR at the end of the incubation period.

Sediment phase
The amount of radioactivity in the sediment immediately after treatment amounted to 50.0% and 36.9% TAR in the Rhine and the Pond system, respectively. The radioactivity reached a maximum of 64.1% and 62.7% TAR on day 2, thereafter it decreased slowly and represented 41.4 and 29.9% TAR at day 105 in the Rhine and the Pond system, respectively.
In the Rhine system the amount of non-extractable radioactivity increased from 1.6% TAR after 6 hours of incubation time to a maximum of 23.2% TAR on day 61. Thereafter, until day 105, an apparent plateau value was observed (= 18.9% TAR on day 105).
In the Pond system the non-extracted radioactivity was higher than for the Rhine system on day 30 and can be explained by the higher amounts of organic carbon present in Pond sediment. For time intervals 6 hours, 30 and 105 days, the corresponding values were 0.9, 37.3, and 21.2% TAR, respectively.

Volatiles
The mineralization of benzyl-14C-alpha-cypermethrin was high in both water/sediment systems (Table 7.2.2.3-3 and Table 7.2.2.3-4). Thus the levels of 14CO2 amounted to 38.0% TAR after 61 days in the Rhine system and only 24.9% TAR were recovered on day 105. In the Pond system, levels of 14CO2 accounted for 49.0 and 53.1% TAR after 61 and 105 days, respectively.
The amount of other volatile compounds was negligible in both systems since it did not exceed 0.1% TAR during the experiment.

Table 7.2.2.3-3: Balance of the applied radioactivity in the Rhine water/sediment system treated with benzyl-^{14}C-alpha-cypermethrin [% TAR] (mean of two replicates)

TAR = Total applied radioactivity
n.d. = Not determined
* Radioactivity determined directly in water
** Includes Sohxlet extraction, for sampling intervals 14 to 105 days.

Extractability of radioactivity from water

The extracted radioactivity by partitioning with ethyl acetate at pH 4 decreased with increasing incubation time, because of the decrease in the amount of radioactivity in water. It represented 49.8% and 61.0% of the total applied radioactivity on day 0 in the Rhine and in the Pond system, respectively. Thereafter, it decreased to 1.0% and 1.7% on day 30 in the Rhine and in the Pond system, respectively.
Between 77 and 100% of the radioactivity in water were recovered by partitioning with ethyl acetate at days 0-7. On days 14 and 30 this amounts were lower (16 to 60% of radioactivity) due to loss of 14CO2 during partitioning. In %TAR this loss of radioactivity amounted to 6.9 and 3.3% in the Rhine system at day 14 and 30 and to 6.7 and 8.2% in the Pond system.
The remaining amount of radioactivity in the aqueous phase was very low and ranged from 0.9% TAR on day 0 to a maximum of 4.3% TAR on day 7 in the Rhine system and 0.2% on day 0 to 5.4% 6 hours after the application in the Pond system.
Analysis of the water phases on day 61 and 105 was not performed, because only very low amounts of the total applied radioactivity (maximum of 1.9% on day 105 in the Rhine system and 2.0% on day 61 in the Pond system) were present in water.

B. TRANSFORMATION OF PARENT COMPOUND

Characterization and identification of residues in water and sediment extracts

An overview of active substance and metabolites for the water samples and sediment extracts is presented in Table 7.2.2.3-5 and Table 7.2.2.3-6.
The radioactive fractions found in water had a similar chromatographic behavior as those found in sediment extracts. Hence, only one notation was used for the same metabolite found in water or sediment for the Rhine and the Pond system, respectively.

Table 7.2.2.3-5: Metabolite overview for water and sediment after application of benzyl-^{14}C-alpha-cypermethrin to the Rhine system [% TAR] (mean of two replicates)

n.p. = Not performed
[a] 3-PBA

Water phase

The amount of benzyl-14C-alpha-cypermethrin (P) in the Rhine River water decreased rapidly from 49.9% TAR at day 0 to 1.4% TAR at day 14. Thereafter, no parent compound was detected.

Besides parent compound, mainly one metabolite (M3) identified as WL 44607 (3-PBA), was found at maximum amounts of 17.3% TAR. Radioactive fraction M2, characterized as WL 46114, was detected in low amounts (≤ 2.6% TAR). In addition, four other minor metabolites (all unknown) were detected in the Rhine River water, but their concentrations did not exceed 3.7% TAR.

Similarly, the test item disappeared rapidly from the water in the Pond system, from 61.2% TAR at day 0 to 8.0% TAR at day 7. Thereafter, no parent compound was detected in water extracts.
The parent compound was degraded to a maximum of eight metabolites during the incubation period. The main degradation product was metabolite M3, identified as WL 44607 (3-PBA), reaching a maximum of 18.0% TAR on day 7. Radioactive fraction M2 (WL 46114) was detected only on day 7 and day 30 and amounted to 1.2 and 2.0% TAR, respectively. Other radioactive fractions (all unknown) were found at maximal amounts of 3.5% TAR.

Sediment phase
The amount of benzyl-14C-alpha-cypermethrin in Rhine sediment increased from 49.3% TAR on day 0 to 54.9% TAR on day 2. Thereafter, the extracted amount decreased to 12.9% TAR (day 105).
Apart from parent compound, six metabolites were detected. The compound M3 (WL 44607,; 3-PBA) reached a maximum of 4.4% TAR at day 7. Other radioactive fractions (M1, M4, M5, M6, M8) reached maximum amounts of 3.4, 4.4, 5.8, 5.3, and 2.3% TAR, respectively.

In the Pond sediment, the extracted amount of the test item increased from 34.9% TAR on day 0 to 46.8% TAR after 2 days. Thereafter, the amount decreased to 2.0% TAR by day 105.
A minimum of ten metabolites were found as well. Metabolite M3 represented a maximum of 5.1% TAR on day 7 and was identified as WL 44607 (3-PBA). Metabolite fractions M1, M4, M5, and M6 were detected at maximum amounts of 3.4, 5.0, 5.3, and 4.1% TAR, respectively. Other radioactive fractions (M2, M7, M5, M9, M10) were detected sporadically, not exceeding 0.7% TAR.

A proposed route of degradation of alpha-cypermethrin in water/sediment systems is given in Figure 7.2.2.3-1.

Characterization of non-extractable residues

After sediment extraction on day 30 and 105 of incubation, 1-2 sediment samples per aquatic system were monitored for the radioactivity bound to humic acids, fulvic acids, and humin fractions. The distribution of radioactivity (in % TAR) is presented in Table 7.2.2.3-7.

Table 7.2.2.3-7: Distribution of radioactivity between fulvic acids, humic acids, and humins after application of benzyl-^{14}C-alpha-cypermethrin to water/sediment systems [% TAR]

DAT	Sample	NER	Fulvic acids	Humic acids	Humins
Rhine system					
30	A	22.4	5.8	7.2	9.4
30	B	18.6	5.1	6.0	7.5
105	B	20.0	6.0	7.9	6.1
Pond system					
30	A	37.2	4.2	6.8	26.2
30	B	37.3	4.0	5.5	27.7
105	A	21.7	2.3	16.4	2.9

TAR = Total applied radioactivity

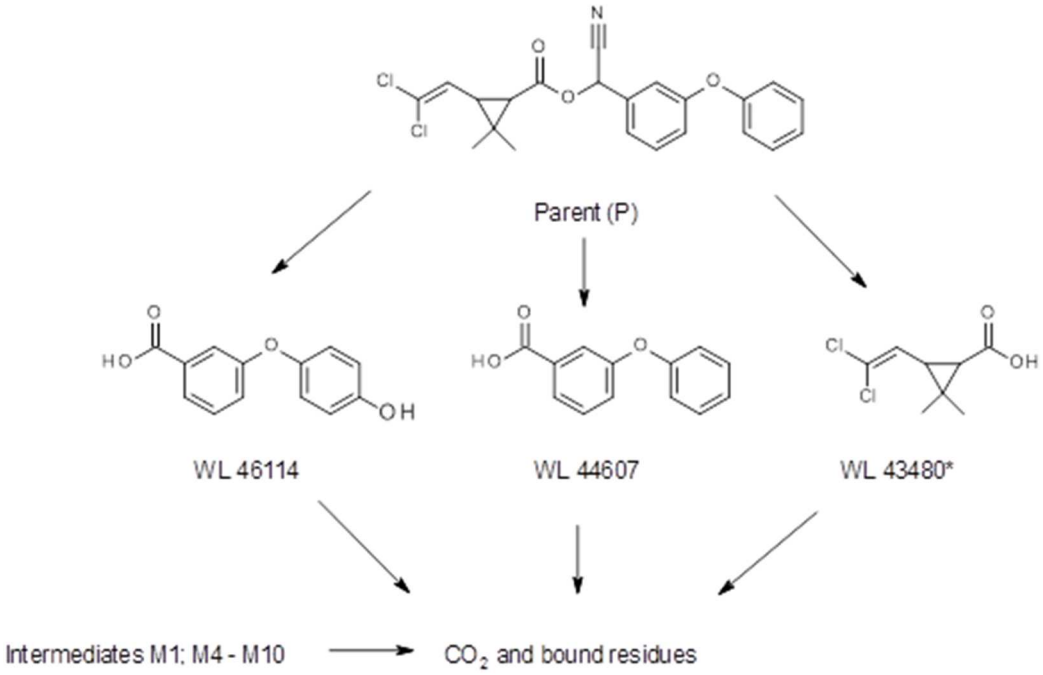
Figure 7.2.2.3-1: Proposed route of degradation of alpha-cypermethrin in water/sediment systems



* detected in study AL-630-012 [VOELKL, S. (1993): 14C-ALPHACYPERMETHRIN (CYCLOPROPYL—1-14C): DEGRADATION AND METABOLISM, BASF DocID 1993/7002022]

Dissipation and degradation rates

The calculation of dissipation and degradation rates in the water/sediment system according to the recommendations of the FOCUS work group on degradation kinetics [FOCUS (2006)] are subject of a separate report provided in section CA 7.2.2.3/3 [BASF DocID 2014/1159506].

III. CONCLUSION

Results revealed that the test item was rapidly eliminated from both aquatic systems at 20°C ± 2°C in the dark. It quickly dissipated in the water phase by hydrolysis, mineralization, and adsorption to sediment. Only 1.6 and 8.0% TAR remained in water after 7 days in the Rhine River and Pond aquatic systems, respectively.
The minera1ization of benzyl-14C-alpha-cypermethrin was very high and amounted to more than 38 and 53% TAR in Rhine River and Pond system, respectively.
The test item in the sediment system was degraded relatively fast as well – at the end of the study the amount of parent compound left amounted to 12.9 and 2.0% TAR of the in the Rhine and the Pond system, respectively.
Non-extractable residues were found at the end of the study in amounts of 18.9% TAR (Rhine) and 21.2% TAR (Pond).

14C-Alphacypermethrin (cyclopropyl-1-14C): Degradation and metabolism in aquatic systems
AL-630-012
Guidelines: BBA IV 5-1
GLP: yes
(certified by Eidgenoessisches Departement des Inneren, Bern, Schweiz)

Executive Summary

The degradation of cyclopropyl-1-14C-alpha-cypermethrin in two aerobic water/sediment systems was investigated: one Rhine River and one Pond aquatic system.

Test vessels were treated with cyclopropyl-1-14C-alpha-cypermethrin with an initial concentration of 0.014 µg L-1 corresponding to a field application rate of about 42 g a.s. ha-1 when assuming that the a.s. is homogeneously distributed in a natural water of 30 cm depth. The test vessels were connected to an aeration system at a temperature of 20 ± 2°C in a dark room. Samples were taken directly after the treatment and 6 hours, 24 hours and 2, 7, 14, 30, 62 and 105 days after application. Water and sediment extracts were analyzed by thin-layer-chromatography. The amount of non-extractable residues was determined by combustion and liquid scintillation counting (LSC). Volatiles were trapped in appropriate trapping solutions and also analyzed by LSC. Metabolite identification was done by co-chromatography with reference substances.

After a lag period of about 30 to 60 days, the parent molecule was rapidly mineralized, resulting in high amounts of 14C-CO2. The mean amount of 14C-CO2 accounted for 33.2% of the total applied radioactivity (TAR) after 105 days in the Rhine system and to 40.0% TAR in the Pond system. The amount of other volatile compounds was very low ≤ 0.2% TAR).

The amount of the test item detected in the water phase of the Rhine system decreased from 48.2% TAR on day 0 to 0.8% TAR after 14 days. Thereafter, the parent molecule was no longer detected. The corresponding values obtained for the water in the Pond system were 49.5% and 2.7% TAR, on day 0 and after 7 days, respectively. After 14 days, the parent molecule was not detectable in the water phase.

Analysis of the water phase revealed that, besides the parent molecule, up to ten and five radioactive fractions in the Rhine system and Pond system were present, respectively.

One major radioactive fraction, designated as RW1 and PW1, was found in the Rhine and Pond system. The chromatographic behavior of this fraction matched with that of the reference WL 43480 (DCVA). This fraction ranged from 2.4% to 29.4% TAR for the Rhine system. The corresponding values for the Pond system ranged from 3.2% to 47.3% TAR.

Radioactive fractions RW7 and RW9, detected in the Rhine water, reached maximum amounts of 8.2% and 11.2% TAR after 105 days of incubation. Radioactive fractions RW2 - RW6, RW8, and RW10 did not exceed 4.9% TAR during the whole incubation time.

One radioactive fraction (PW3), detected in the Pond water, reached a maximum amount of 8.9% TAR at one sampling occasion. The other radioactive fractions present did not exceed an amount of 3.4% TAR.

Extraction of the soil sediments showed an increasing amount of radioactivity from 41.0% TAR on day 0 to a maximum amount of 59.0% TAR on day 14. Afterwards, the amount decreased to 26.1% TAR until 105 days of incubation for the Rhine system. The corresponding values obtained for the Pond system were 42.6% TAR on day 0, 52.6% TAR after 7 days, and 8.5% TAR after 105 days, respectively.

Analysis of the extractable radioactivity showed that besides the parent molecule up to six and seven radioactive fractions for Rhine and Pond system were present, respectively.

Radioactive fractions RS1 and PS1 represented the main metabolite, characterized as reference WL 43480 (DCVA). They were detected from day 1 onward and occurred for a maximum amount of 9.5% and 19.3% TAR in the Rhine and Pond system, respectively. One radioactive fraction in the Rhine sediment, designated as RS2, reached a maximum amount of 10.3% TAR. Other radioactive fractions were present at lower percentages, accounting for a maximum of 5.6% TAR.

The results obtained indicated, that the elimination of test item from the total aquatic system was dependent from the organic carbon content of the sediments (Rhine system: 0.9 g C x100 g-1 dry soil and Pond system 5.4 g C x100 g-1 dry soil). Thus, in the Rhine system 22.6% TAR were present in water at the end of the study and 8.9% TAR in the Pond system. Furthermore, higher amounts of 14C-CO2 (see above) and bound residues were formed in the Pond system.
Bound residues were formed in amounts of 37.1% TAR in the Pond system compared to 16.2% TAR in the Rhine system.

From these results and with respect to the study design, it could be stated that the elimination of cyclopropyl-1-14C-alpha-cypermethrin from the water phase proceeded mainly via rapid degradation to polar metabolites. After a lag period of 30 to 60 days, mineralization and adsorption to the humin, humic, and fulvic acid fractions in the sediments took place.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test Material

Internal code: BAS 310 I
Reg. No.: 4078193
CAS Number: 67375-30-8
Chemical name: 1:1 mixture of (S)-alpha-cyano-3-phenoxybenzyl-(1R,3R)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate and (R)-alpha-cyano-3-phenoxybenzyl-(1S,3S)-3-(2,2-dichlorovinyl)-2,2-dimethyl cyclopropanecarboxylate
Molecular formula: C22H19Cl2NO3
Molecular mass: 418.0 g mol-1
Label: cyclopropyl-1-14C
Specific activity: 134 mCi g-1
Radiochemical purity: 99% (checked by RCC using TLC in at least two solvent systems)

2. Test system

Two different test systems were applied:

System I Rhine-river water + Rhine sediment (Rhine, Mumpf/ Switzerland)
System II Pond water + Pond sediment (Pond, “Judenweiher”/Switzerland)

The physico-chemical properties of the systems are summarized in Table 7.2.2.3-8.

Table 7.2.2.3-8: Characterization of the water/ sediment system

B. STUDY DESIGN

1. Experimental conditions

The study was performed in an open gas-flow-system in 1000 mL all-glass metabolism flasks containing about 275 g and 190 g of sediment for the Rhine and Pond aquatic systems, respectively, and 550 mL of water. The system was ventilated with moistened CO2-free air with simultaneous gentle agitation of the water column by means of a suspended magnetic stirrer. The out coming air was passed through a trapping system of two bottles of 2N NaOH (50 mL) and one bottle of ethylene glycol (50 mL).

The water/sediment systems were incubated at 20 ± 2°C in the dark until an equi1ibrium based on measurable variables was reached. For this purpose, the oxygen concentration, pH and redox potential of selected samples were measured after the colloidal particles had settled down. One day before the application of the test article, the oxygen concentration, pH and redox potential of all samples were determined.

Aliquots of 390 µL containing 7.8 µg of cyclopropyl-14C-alpha-cypermethrin in acetone were applied drop-wise to each flask. Reserve as well as control flasks were included in the study. By applying the maximum recommended field rate of 42 g cyclopropyl-1-14C-alpha-cypermethrin ha-1 and assuming that the test item is homogeneously distributed in the top 30 cm of the water column a target concentration of 14 µg L-1 was achieved.

The microbial biomass of the sediments was determined at the start of the incubation period and at the end of the experiment in the control samples.

2. Sampling

Samples of water and sediment were taken for analysis directly after the treatment and 6, 24, 48 hours and 7, 14, 30, 62 and 105 days after application. For each sampling day, duplicates from each system, Rhine and Pond, were analyzed. The water was sampled down to a depth of 10-30 cm and the sediment was sampled from the top 5-10 cm of each system. This sampling site was located 1-2 m from firm land.

Volatile traps
The absorption solutions were replaced on each sampling interval or about every two weeks and monitored for 14C-CO2 and volatiles.

3. Analytical procedures

Water phase
After separation from sediment, the radioactivity in the water was determined directly by LSC.
Aliquots of up to 300 mL of the water phase were submitted to partitioning with ethyl acetate for two times. In order to obtain a balance, aliquots of the water phases after extraction as well as the radioactivity extracted with ethyl acetate were sampled and submitted to LSC.
The radioactivity remaining in the water phase after extraction was designated as unresolved radioactivity (Table 7.2.2.3-11 and Table 7.2.2.3-13).

Sediment phase
The sediment samples were submitted to the following extractions:
1. - 1-4 times with acetonitrile. The acetonitrile extracts were combined and concentrated under reduced pressure and submitted to TLC-analysis
2. For samples obtained on days 30, 62 and 105, a Soxhlet extraction of the sediments was performed with acetonitrile for about 16 hours. The Soxhlet samples were not analyzed due to their low radioactivity level.

After extraction, aliquots of the sediment samples were submitted to combustion in order to determine the amount of non-extractable radioactivity.

Characterization of bound residues
Organic matter fractionation was performed on sediment samples from sampling day 105 after extraction. Only one sample from the river and Pond sediments per interval was used. This fractionation was performed by extraction of the soil sample with 0.5 M NaOH solution, thereafter, the humic acids were precipitated by decreasing the pH to about 1. Centrifugation permits separation of the fulvic acids which remain in the liquid phase. The humin fraction remains unextracted together with the clay mineral and aluminum oxides.

Volatiles
Radioactivity in the volatile trapping solutions was determined by LSC.

4. Kinetic modeling

The kinetic analysis was carried out according to previous requirements in the summarized study. A new kinetic analysis following the recommendations of the FOCUS work group on degradation kinetics [FOCUS (2006)] will be provided in section CA 7.2.2.3/3 [BASF DocID 2014/1159506].

II. RESULTS AND DISCUSSION

A. MASS BALANCE

Total mean recoveries were 94.3% TAR for water/sediment system I (Rhine; Table 7.2.2.3-9) and 100.8% TAR for system II (Pond; Table 7.2.2.3-10), respectively. These recoveries result from hydrosoil, water and volatile substances, as described below (mean over all replicates).

Water phase
The level of radioactivity in the Rhine-river water decreased from 53.7% TAR at day 0 to 22.6% TAR after 105 days (Table 7.2.2.3-9). The radioactivity level in Pond detected at day 0 amounted to 55.5% TAR and decreased to 8.9% TAR at day 105 (Table 7.2.2.3-10).

Sediment phase
The extractable amount of radioactivity (ERR) in the Rhine-river sediment amounted to 41.0% TAR at day 0 and increased to 73.7% TAR at day 2. Thereafter, ERR decreased to 26.1% TAR at day 105. The non-extractable radioactivity was low until day 14, ranging from 1.9% TAR at day 0 to 6.1% TAR after 14 days (Table 7.2.2.3-9). Thereafter, the non-extractable amount accounted for 16.9% and 16.2% TAR after 60 and 105 days, respectively.

The extractable amount of radioactivity in the Pond system increased from 42.6% on day 0 to a maximum amount of 57.4% TAR on day 2. Until the end of incubation, it decreased to 8.5%. The non-extractable radioactivity was low until day 7, increasing from 2.3% at day 0 to 7.4% TAR. Thereafter, it increased to 37.1% TAR after 105 days of incubation (Table 7.2.2.3-10).

Volatiles
Mineralization of cyclopropyl-1-14C-alpha-cypermethrin was significant in the Rhine system. After a lag period of 60 days, the mineralization reached 33.2% TAR on day 10, (Table 7.2.2.3-9). The amount of other volatile compounds was very low (≤ 0.2% TAR).

Slightly lower amounts of 14C-CO2 were found within the first 60 days after incubation in the Pond system. After a lag period of 60 days, 8.1% TAR were determined to be 14C-CO2 on day 60, increasing to 40.0% TAR after 105 days, respectively. The volatile radioactivity trapped in ethylene glycol did not exceed 0.2% TAR (Table 7.2.2.3-10).

A proposed route of degradation of alpha-cypermethrin in water/sediment systems is given in section CA 7.2.2.3/1 *[MAMOUNI, A. (1993): FASTAC (BENZYL-14C): DEGRADATION AND METABOLISM IN AQUATIC SYSTEMS, BASF DocID 19937002021].*

Water phase

The amount of parent substance decreased from 48.2% TAR at day 0 to 0.7% TAR at day 7. At day 14, the parent molecule was only detected for one replicate. Besides the parent compound, up to ten metabolite fractions (RW1 - RW10) were found in the Rhine river water. RW1 represents the main metabolite fraction. Its chromatographic behavior matched with that of reference compound WL 43480 (DCVA). It could be detected unti1 day 30, starting from 2.4% TAR after 6 hours to its maximum of 29.4% TAR on day 14 and ending at 26.9% TAR after 30 days of incubation. Radioactive fractions RW2, RW3, RW4 RW5, RW6, RW8 and RW10 were detected at a maximum amount of 4.9% TAR (0.0007 mg parent equivalents kg-1).

Radioactive fractions RW7 and RW9 were the main radioactive fractions after 60 days and 105 days of incubation. They reached a maximum amount of 8.2% and 11.2% TAR after 105 days of incubation, respectively. The metabolite fractions RW9 and RW7 remained unknown. Its chromatographic behavior did not match with that of reference compound WL 47133. The very low Rf values of metabolites RW7 and RW9 as well as their increase after the dissipation of DCVA allow the conclusion that they are oxidation products of DCVA, most likely hydroxylated at one of the methyl groups (RW7, M310I003) and further oxidized to a dicarboxylic acid (RW9).

The radioactivity that was not extractable from the water phase by partitioning was designated as unresolved radioactivity. It did not exceed 5.5% TAR.

The amount of parent substance in the Pond water decreased continuously from 49.5% TAR at day 0 to 2.7% TAR after 7 days of incubation.
Besides the parent molecule, up to five radioactive fractions, designated as PW1 to PW5, were detected in the Pond water. PW1 represented the main radioactive. The chromatographic behavior of this fraction matched with that of the reference compound WL 43480 (DCVA). Its amount increased from 3.2% TAR after 6 hours to its maximum amount of 47.3% TAR after 14 days of incubation. Thereafter, it decreased to 17.9% TAR after 60 days of incubation.
Radioactive fraction PW2 was present at oscillating values. The amount ranged between 1.6% TAR after 6 hours of incubation and 3.4% TAR after 48 hours of incubation time.
Radioactive fraction PW3 occurred from day 1 onward also at oscillating amounts. The amount detected ranged from 2.6% to 8.9% TAR. This fraction shows a similar chromatographic behavior as fraction RW9 detected in water of the Rhine system.
PW4 and PW5 represented highly polar fractions not exceeding 2.9% TAR.
The amount of radioactivity which was not extracted by partitioning was designated as unresolved radioactivity. Its amount did not exceed 6.3% TAR.

Sediment phase
Besides the parent molecule, up to six radioactive fractions (RS1 - RS6) were detected in the Rhine sediment. The amount of the parent molecule increased from 37.0% TAR immediately after application to a maximum amount of 61.8% TAR on day 2 and decreased thereafter to 17.0% TAR on day 105.
Radioactive fraction RS1 represented the main metabolite in the sediment of the Rhine system. Its chromatographic behavior matched with that of reference WL 43480 (DCVA). This fraction was detected first immediately after application with 1.5% TAR and amounted to 9.0% TAR after 30 days of incubation. After 105 days of incubation it accounted for 1.8% TAR.
Radioactive fraction RS2 was present from day 0 onward until day 14 and on day 60 and 105. The amount detected for RS2 started from 2.5% TAR on day 0 to a maximum amount of 10.3% after 2 days of incubation. Thereafter, its amount decreased to 2.8% and 2.2% TAR after 14 and 105 days of incubation.
Radioactive fractions RS3 to RS6 were detected irregularly. They did not exceed 5.6% TAR.

Beside the parent molecule, up to seven radioactive (PS1 -PS7) fractions were detected in the Pond sediment. The amount of the parent molecule increased from 40.8% TAR on day 0 to a maximum amount of 51.9% TAR after 2 days of incubation. Thereafter, the amount decreased to 1.6% TAR after 105 days of incubation.
Radioactive fraction PS1 was the main metabolite in the Pond system and matched with reference compound WL 43480 (DCVA). This fraction amounted from 1.8% TAR on day 0 to 19.3% TAR on day 14 and decreased to 1.4% TAR on day 105.
Radioactive fractions PS2 to PS7 did not exceed 6.6% TAR.

Characterization of non-extractable residues

After sediment extraction on day 105 of incubation, one sediment sample per aquatic system was monitored for the radioactivity bound to humic acids, fulvic acids, and humin fractions. The distribution of radioactivity (in % TAR) is presented in Table 7.2.2.3-15.

Table 7.2.2.3-15: Distribution of radioactivity between fulvic acids, humic acids, and humins after application of cyclopropyl-1-^{14}C-alpha-cypermethrin to water/sediment systems [% TAR]

DAT	Sample	NER	Fulvic acids	Humic acids	Humins
105	River sediment, sample A	16.6	7.4	5.4	3.8
105	Pond sediment, sample A	40.6	6.9	23.6	10.1

TAR = Total applied radioactivity
DAT = Days after treatment
NER = Non-extractable radioactivity

Dissipation and degradation rates

The calculation of dissipation and degradation rates in the water/sediment system according to the recommendations of the FOCUS work group on degradation kinetics [FOCUS (2006)] are subject of a separate report provided in section CA 7.2.2.3/3 [BASF DocID 2014/1159506].

III. CONCLUSION

The present study showed that cyclopropyl-1-14C-alpha-cypermethrin was rapidly eliminated from both aquatic systems at 20°C ± 2°C in the dark.
The disappearance of the parent compound from the water phase by hydrolysis and mineralization and adsorption into sediment was relatively rapid in both systems, only 0.7% and 2.7% TAR remained in water after 7 days in the Rhine River and Pond aquatic systems, respectively.
For both systems, several radioactive fractions were detected. One radioactive fraction designated as RW1 and PW1 in the water phase of the Rhine and Pond as well as RS1 and PS1 occurring in the sediments of the systems represented the main metabolite of cyclopropyl-1-14C-alpha-cypermethrin, which was rapidly further degraded. The chromatographic behavior of these fractions matched with that of the reference compound WL 43480 (DCVA). The maximum amount detected for this fraction was 29.4% TAR in the Rhine water and 47.3% TAR in the Pond water.
The minera1ization of cyclopropyl-1-14C-alpha-cypermethrin was very high and amounted to more than 33 and 40% TAR in Rhine-river and Pond system, respectively.

The rate of degradation in sediment was higher in the Pond system because of the higher microbial activity. Higher adsorption did not prevent further mineralization.

Report: CA 7.2.2.3/3

Kinetic evaluation of degradation of BAS 310 I - alpha-cypermethrin in water/sediment systems: Determination of trigger and modeling endpoints according to FOCUS
2014/1159506
Guidelines: none
GLP: no

Executive Summary

The aim of the study was to evaluate the dissipation and degradation kinetics of alpha-cypermethrin and its metabolites 3-PBA, DCVA, RS2, and RW9/RS5 in two aerobic water/sediment systems with two different labels [*BASF DocID 1993/7002021 (AL-630-011) and BASF DocID 1993/7002022 (AL-630-012)]* and to derive trigger and modeling endpoints according to the recommendations of FOCUS kinetics.

In the two laboratory studies, the degradation of alpha-cypermethrin was investigated over a period of up to 105 days in two water/sediment systems called System I and II (a river and a pond located in Switzerland). Two different radio-labels of the active substance were used in the studies. The experimental data were evaluated using single first order (SFO), first-order multi-compartment (FOMC), double first-order in parallel (DFOP) and hockey stick (HS) kinetic models at the evaluation levels P-I, P-II, and M-I (dissipation and degradation).

The evaluation at Level P-I resulted in reliable trigger and modeling half-lives, except for the sediment phase of System I (cyclopropyl label). DegT50 values for the whole system ranged from 3.0 to 4.7 days as trigger endpoints and from 5.4 to 1000 days (default value) as modeling endpoints. The evaluation at Level P-II did not result in reliable fits for any of the evaluated water/sediment systems.

Dissipation half-lives for the metabolites at Level M-I for the whole system derived as trigger as well as modeling endpoints ranged from 10.2 to 12.5 days for 3-PBA and from 23.2 to 35.3 days for DCVA. Degradation half-lives for the metabolites 3-PBA and DCVA at Level M-I for the whole system derived as trigger as well as modeling endpoints ranged from 7.6 to 8.5 days and from 25.5 to 30.3 days, respectively. No dissipation and degradation endpoints could be derived for metabolite RS2, for metabolite RW9/RS5, only a formation fraction could be calculated.

I. MATERIAL AND METHODS

Kinetic evaluation of the dissipation and degradation behavior of alpha-cypermethrin and its metabolites 3-PBA, DCVA, RS2, and RW9/RS5 was conducted for two aerobic water/sediment studies in the dark with two natural aerobic aquatic systems. The studies are summarized in section *CA 7.2.2.3/1 [BASF DocID 1993/7002021 (AL-630-011)*] and section *CA 7.2.2.3/2 [BASF DocID 1993/7002022 (AL-630-012*)]. The water/sediment systems were taken from the river Rhine (System I) and pond Judenweiher (System II), both located in the area close to Rheinfelden, Switzerland. Kinetic evaluation was performed in order to derive degradation and dissipation parameters as triggers for additional work (trigger endpoints) and for modeling purposes (modeling endpoints) according to the recommendation of the FOCUS workgroup on degradation kinetics [*FOCUS (2006*)].

Two radio-labels of the active substance, referred to as benzyl- [*BASF DocID 1993/7002021 (AL-630-011)*] and cyclopropyl-label [*BASF DocID 1993/7002022 (AL-630-012)*] were used. The test vessels were treated at a rate corresponding to a field application rate of about 42 g a.s. ha-1. The test system was incubated for up to 105 days at 20°C in the dark.

Kinetic modeling

The appropriate kinetic model was identified considering the procedures and kinetic models proposed by the FOCUS workgroup on degradation kinetics [FOCUS (2006)]. According to FOCUS, degradation and dissipation endpoints were derived for use as triggers for future work and for use as modeling inputs.

Kinetic models included in the assessment

Kinetic evaluation at Level P-I (one-compartment approach) was performed for alpha-cypermethrin (both labels) degradation in the total system as well as dissipation from the water and sediment phase of the test systems.

At Level P-II (two-compartment approach: water and sediment), the kinetic analysis considered the degradation in water and sediment and the partitioning between both phases.

Kinetic evaluation at Level M-I dissipation (one-compartment approach) was performed for the metabolites 3-PBA (benzyl label) and DCVA (cyclopropyl label) which were observed in both compartments and the metabolite RS2 which was only observed in the sediment phase of the cyclopropyl label. For DCVA for the water phase of System I, where no decline of the residues was observed, no kinetic evaluation at Level M-I dissipation was performed. The metabolite RW9/RS5 was not included at this level as there was no decline of the residues observed during the study. Estimation of persistence as well as modeling endpoints was based on metabolite decline from the maximum observed concentration in the total system and in the water and sediment phase.

In addition, the degradation of the metabolites 3-PBA, DCVA, and RW9/RS5 in the total system was assessed at Level M-I degradation by kinetic evaluation of the complete degradation pathway with a combined fit of parent and metabolites. 3-PBA and DCVA were assumed to be formed directly from alpha-cypermethrin while RW9/RS5 was assumed to be formed from DCVA. The metabolite RS2 was not included at this level as only its concentration in the sediment was reported and there was no information available on its possible occurrence in the water phase.

As the purpose of the study was to derive modeling and trigger endpoints, all four kinetic models proposed by FOCUS were used during the evaluation (SFO, FOMC, DFOP and HS). Details on the models are given in the FOCUS Kinetics guidance [*FOCUS (2006*)].

At Level P-I and M-I dissipation, trigger endpoints were derived from the kinetic models that provided the best fit to the measured data, generally indicated by the lowest $\chi 2$ - error. Modeling endpoints were derived preferably from the SFO model. If the SFO model was not appropriate, pragmatic procedures were used to derive conservative pseudo-SFO degradation rates from the appropriate bi-phasic model.

The appropriateness of a distinct kinetic model to describe degradation can be tested with the following checks recommended by FOCUS [*FOCUS (2006*)]:

Visual assessment of goodness-of-fit
Estimation of the error percentage at which the $\chi 2$ test is passed [*Equation 6-2 in FOCUS (2006)]*
t-test to evaluate whether estimated degradation parameters differ from zero.

A kinetic model is considered appropriate if the residuals are randomly distributed, the $\chi 2$ - error value is low (ideally below 15% but larger values may be acceptable if the visual fit is acceptable) and the t-test for the degradation parameters is passed at 10% error level.

Data handling

At Level P-I and P-II of the analysis as well as at Level M-I degradation, the kinetic evaluation started on the day of treatment (i.e. 0 DAT). The initial concentration of the parent substance in the total system or in water was set to the material balance recovered at 0 DAT as recommended by FOCUS [*FOCUS (2006)*]. Accordingly, the initial concentration in the sediment phase was assumed to be zero at Level P-II.

The assessment of dissipation in sediment at Level P-I and in all compartments at Level M-I dissipation only requires kinetics to be fitted to the corresponding decline data, starting from the maximum observed concentration in the compartment. The dissipation of the respective compound was thus evaluated starting at the day of maximum occurrence that was defined as 0 days after maximum concentration (0 DAMC). All later time points were adjusted accordingly as days after maximum concentrations (DAMC).

Values below the quantification (LOQ) or detection limit (LOD) for parent compound and degradation products were treated as recommended by FOCUS [*FOCUS (2006)*]. The LOD in water and sediment determined in study conducted with the cyclopropyl-labeled test item [*BASF DocID 1993/7002022 (AL-630-012)*] amounted to 0.07 ppb which corresponds to 0.5% TAR. The LOD retrieved from the study conducted with the benzyl-labeled test item [*BASF DocID 1993/7002021 (AL-630-011)]* was given as 0.05 ppb which corresponds to 0.4% TAR.

Software for kinetic evaluation

The software package KinGUII (version 2.2014.224.1704) was used for parameter fitting [BASF DocID 2007/1062781; WITT, J., GAO, Z., MEYER, H. (2014)].

Experimental data

The experimental data of alpha-cypermethrin and its metabolites 3-PBA, DCVA, RS2, and RW9/RS5 used as model input values for the kinetic evaluations are given in Table 7.2.2.3-16 and Table 7.2.2.3-17 (benzyl label [*BASF DocID 1993/7002021 (AL-630-011)*]) and Table 7.2.2.3-18 and Table 7.2.2.3-19 ([*BASF DocID 1993/7002022 (AL-630-012*)]).

II. RESULTS AND DISCUSSION

The datasets for each water/sediment system were analyzed considering the procedures and kinetic models proposed by the FOCUS workgroup on degradation kinetics [FOCUS (2006)]. The complete fitting procedure is given in the original study report.

Level P-I

The evaluation of both test systems for both labels at Level P-I resulted in reliable endpoints for alpha-cypermethrin for degradation in the total system as well as for dissipation in the water and sediment phase, except for the sediment phase of System I (cyclopropyl label) where no acceptable fit was obtained.

An overview of the estimated trigger and modeling endpoints for alpha-cypermethrin in both water/sediment systems is given in Table 7.2.2.3-20 and Table 7.2.2.3-21.

Table 7.2.2.3-20: Trigger endpoints for alpha-cypermethrin at Level P-I

Label, System	Total system		Water		Sediment

[b] Calculated as $DT_{50} = \ln 2/k2$
[c] Default value as calculated $DegT_{90}$ value was >1000 days.

Level P-II

The kinetic evaluation revealed no reliable fit for any of the evaluated water/sediment systems. Consequently, no trigger or modeling endpoints were calculated.

Level M-I dissipation

Trigger and modeling endpoints at Level M-I dissipation were calculated for the metabolites 3-PBA and DCVA for the total system, the water, and sediment phase of all water/sediment systems, except for DCVA for the water phase of System I where no decline of the residues was observed. For the metabolite RS2, the kinetic evaluation at Level M-I dissipation was conducted for the sediment phase of System I (cyclopropyl label) but did not result in an acceptable fit. The metabolite RW9/RS5 was not considered for the evaluation at Level M-I dissipation as there was no decline of the residues observed. In each case, SFO was selected as the most appropriate kinetic model to derive trigger as well as modeling endpoints. The results for the metabolites 3-PBA and DCVA are summarized in Table 7.2.2.3-22 and Table 7.2.2.3-23.

Table 7.2.2.3-22: Summary of trigger and modeling endpoints for 3-PBA, Level M-I dissipation

n.c. = Not calculated (no decline observed)
[a] SFO selected as best-fit model; also used or derivation of modeling endpoints

Level M-I degradation

Trigger and modeling endpoints at Level M-I degradation for the metabolites 3-PBA, DCVA, and RW9/RS5 were derived from combined fitting of all data of parent and metabolites from the total system considering the best-fit model for the parent as derived at Level P-I and the SFO model for the metabolites. For 3-PBA and DCVA, formation from the parent was assumed as degradation pathway while RW9/RS5 was assumed to be formed from DCVA. A summary of the results for the metabolites 3-PBA, DCVA, and RW9/RS5 are shown in Table 7.2.2.3-24 to Table 7.2.2.3-26.

Table 7.2.2.3-24: Summary of trigger and modeling endpoints for 3-PBA, Level M-I degradation

Label, System	Kinetic model	Trigger endpoints		Modeling endpoints	
		$DegT_{50}$ [d]	$DegT_{90}$ [d]	$DegT_{50}$ [d]	Formation fraction

III. CONCLUSION

The dissipation and degradation kinetics of alpha-cypermethrin and its metabolites 3-PBA, DCVA, RS2, and RW9/RS5 in two water/sediment systems were evaluated according to the recommendations of the FOCUS workgroup on degradation kinetics [FOCUS (2006)]. The visual assessment and goodness-of-fit statistics of the respective models indicate plausible fit. Therefore, the resulting endpoints can be considered reliable.

The experimental data of alpha-cypermethrin and its metabolites 3-PBA, DCVA, RS2, and RW9/RS5 in both test systems (Systems I and II) and for both labels (benzyl and cyclopropyl) were evaluated at Level P-I, Level P-II, and Level M-I (dissipation and degradation).

The evaluation at Level P-I resulted in reliable trigger and modeling half-lives, except for the sediment phase of System I (cyclopropyl label). DegT50 values for the whole system ranged from 3.0 to 4.7 days as trigger endpoints and from 5.4 to 1000 days (default value) as modeling endpoints.

Dissipation half-lives for the metabolites at Level M-I for the whole system derived as trigger as well as modeling endpoints ranged from 10.2 to 12.5 days for 3-PBA and from 23.2 to 35.3 days for DCVA. Degradation half-lives for the metabolites 3-PBA and DCVA at Level M-I for the whole system derived as trigger as well as modeling endpoints ranged from 8.5 to 7.6 days and from 25.5 to 30.3 days, respectively. No dissipation and degradation endpoints could be derived for metabolite RS2, for metabolite RW9/RS5, only a formation fraction could be calculated.

Supplementary information on the behaviour of alpha-cypermethrin in water/sediment systems from literature

Though the studies were not performed with alpha-cypermethrin, conclusion for this compound can be drawn.

"Laboratory Degradation Rates of 11 Pyethroids under Aerobic and Anaerobic Conditions" (J. Agric Food Chem. 2013, 61, 4702-4708)
2013/1416300
Guidelines: yes
GLP: no

Executive Summary

Laboratory experiments were conducted to determine degradation rates of 11 pyrethroids (including ζ-cypermethrin and cypermethrin) in water / sediment systems incubated under aerobic and anaerobic conditions at 25 ± 1°C and darkness.

Three sediment samples originating from three different sites and with different physico-chemical properties were combined with water and tested in this study. ζ-cypermethrin and cypermethrin were applied separately in two test mixtures containing other pyrethroids at a nominal concentration of 50 µg kg-1. Water / sediment samples were incubated from zero to 100 days. Samples were extracted with acetonitrile followed by two steps of solid phase extraction (SPE). Analyses were performed by gas-chromatography/mass spectrometry (GC-MS).

Degradation rates were calculated for the overall system, and no attempt was made to distinguish between material in the solution or sediment phases.
Degradation rates appeared to follow SFO kinetics until approximately 50 – 75% of the applied pesticide was degraded. Afterwards, degradation rates slowed down. Degradation was faster under aerobic than under anaerobic conditions. Degradation of ζ-cypermethrin was slightly slower with calculated DT50 values (best fit kinetics if endpoint reached within incubation period) ranging from 4 to 13 days (DT90: 51 days - > end of study period) under aerobic conditions and 26 to 33 days under anaerobic conditions (DT90: > end of study period). DT50 values of cypermethrin ranged from 2.7 to 8.6 days (DT90: 23 - 100 days) when incubated under aerobic conditions and from 13 to 20 days when incubated under anaerobic conditions (DT90: 90 days - > end of study period). The aerobic degradation rate was the slowest for sediment 2, which possessed the highest organic carbon content, while differences in the anaerobic degradation rates were less pronounced.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test material

The eleven test items were grouped into two treatment mixtures. The isomeric analytes were placed into different test mixtures. Hence, ζ-cypermethrin (test mixture 1) and cypermethrin (test mixture 2) were applied separately to the water/sediment samples.

2. Test sites

The sediments used in this study were sediments originating from three sites in California (USA). They differed widely in their physico-chemical properties (e.g., organic carbon content and texture), shown in Table 7.2.2.3-27.

Table 7.2.2.3-27: Soil properties of soil used to investigate degradation rate of cypermethrin and ζ-cypermethrin in sediment

Soil designation origin	**Sediment 1** East of San Diego	**Sediment 2** King Island	**Sediment 3** Contra Costa
Sand [%]	90.3	20.4	49.5
Silt [%]	1.8	30.1	25.9
Clay [%]	7.9	49.5	24.6
Textural class	Sand	Clay	Sandy clay loam
Total organic carbon [%]	0.6	7.4	2.7
pH ($CaCl_2$)	6.4	5.8	6.6
Cation exchange capacity [meq/100 g dry soil]	6.0	19.0	14.8

B. STUDY DESIGN

1. Sampling and analysis

All sediments were sieved to a particle size of ≤ 2mm. Because water was not present in some of the sediments surveyed for inclusion in this study, water was not collected with the sediment. Instead, conditioned water typically used for aquatic studies in the Ecotoxicology Department at the Bayer Facilities in Stilwell, KS, was used.

150-270 mL water was added to 25-50 g sediment, depending on the respective sediment properties. Prior to treatment, a pre-incubation period (12-32 days) was used to acclimate and establish the appropriate conditions (aerobic or anaerobic) in the systems as judged by dissolved oxygen and redox. In the aerobic experiment, flasks containing the water / sediment samples were supplied with humidified air and were incubated at 25 ± 1°C and darkness. Incubation was the same for anaerobic incubated samples, but sample flasks were purged with nitrogen instead of air. Additional control samples were incubated as well under the same conditions. Test mixtures 1+2 were applied separately to the samples at a nominal concentration of 50 µg kg-1 sediment (dry weight equivalent). Incubation was performed under the above mentioned conditions. Dissolved oxygen, pH and redox potential were measured continuously. Microbiological activity was determined at day 0 and day 100 by aerobic or anaerobic plate counts.

Samples were collected in duplicates at seven time intervals (0, 3, 7, 14, 28, 60 and 100 days after treatment). For sample workup, 250 mL acetonitrile was added to the test vessels, the sample was transferred to 1 L plastic bottles, and shaken for 30 min. After vacuum filtration, solid phase extractions (SPE) were performed for sample clean-up and pre-concentration. Therefore, filtrates were extracted first with a 1 g ENVI-Carb cartridge (Sigma-Aldrich, St. Louis, MO, USA). The SPE cartridge was rinsed with acetonitrile / water (3:2, v/v) and methanol, and eluted with dichloromethane (DCM). This solution (dried and redissolved in DCM/cyclohexane [2:3, v/v]) was extracted in a second SPE step using a 1 g NH2 cartridge (Agilent Technologies, Santa Clara, CA, USA). Cartridges were rinsed again with DCM : cyclohexane (2:3, v/v). After adding an internal standard (cyfluthrin-d6), samples were concentrated to dryness, redissolved in cyclohexane and analyzed by gas-chromatography/mass spectrometry (GC-MS).

Analyses were performed using a GC-MS system (Trace GC Ultra; Thermo Scientific) and a Rtx-5MS capillary column (Restek Corporation, Bellefonte, PA, USA).

The limit of quantification (LOQ) was 5.0 ppb for all analytes/test systems, the limit of detection (LOD) ranged from 0.2 – 1.4 ppb depending on the analyte/test system.

2. Kinetic evaluations

Kinetic evaluations were performed using KinGUI 1.1using criteria specified by the FOrum for Co-ordination of pesticide fate models and their USe (FOCUS) [FOCUS (2006)], applying single first-order (SFO) and first-order in parallel (DFOP) kinetics.

Determination of the microbial activity revealed that the test systems remained microbially active until the end of the study.

The analysis method was validated by investigating five replicate test systems with freshly spiked sediment samples at fortification levels of 5 and 50 ppb (each test mixture). Average recoveries of test mixture 1 (containing ζ-cypermethrin) were between 74 and 106% of the applied amounts (relative standard deviation (RSD): 1-8%) and between 72 and 107% of the applied amounts (RSD: 1-13%) for test mixture 2 (containing cypermethrin).

Procedural recoveries of all analyzed samples ranged from 71 to 114% with an overall mean of concurrent of 95.8% (standard deviation (SD): 6.2%). Therefore, residue values were not corrected for concurrent recovery results.

Residue concentrations of ζ-cypermethrin and cypermethrin declined in all of the total water / sediment systems, but the rates of decline varied among the three tested sediments. The authors mentioned that the degradation rates appeared to follow SFO kinetics until approximately 50 – 75% of the applied pesticide was degraded. Afterwards, degradation rates slowed down. Degradation was faster under aerobic than under anaerobic conditions. Degradation of ζ-cypermethrin was slightly slower with calculated DT50 values (best fit kinetics if endpoint reached within incubation period) ranging from 4 to 13 days (DT90: 51 days - > end of study period) under aerobic conditions and 26 to 33 days under anaerobic conditions (DT90: > end of study period). DT50 values of cypermethrin ranged from 2.7 to 8.6 days (DT90: 23 – 100 days) when incubated under aerobic conditions and from 13 to 20 days when incubated under anaerobic conditions (DT90: 90 days - > end of study period). The slowest aerobic degradation rate was found for sediment 2, which possessed the highest organic carbon content. Differences in the anaerobic degradation rates were less pronounced.
First-order half-life values ranged from 5.0 to 21.6 days (ζ-cypermethrin) and 3.0 to 14.1 days (cypermethrin) under aerobic conditions, respectively, and from 32.0 to 46.3 days (ζ-cypermethrin) and 20.1 to 24.5 days (cypermethrin) under anaerobic conditions.

The authors admit that the degradation rates of ζ-cypermethrin and cypermethrin were in the range observed in previous studies conducted with single analytes, revealing that the mixture of compounds had no impact on the observed degradation rates.

III. CONCLUSION

Degradation rates for ζ-cypermethrin and cypermethrin were determined in water / sediment systems for the whole system under aerobic and anaerobic conditions. DT50 values for ζ-cypermethrin and cypermethrin ranged from 2.7 to 13 days under aerobic conditions (DT90 from 51 days to > end of study period) and from 13 to 33 days under anaerobic conditions (DT90: 90 days - > end of study period).

In this study a fast degradation following a biphasic kinetic of cypermethrins was observed. This confirms the results from the water/sediment guideline studies (Mamouni, 1993, CA 7.2.2.3/1 and Voelkl 1993, CA 7.2.2.3/2).

In the water sediment studies from Mamouni, 1993, CA 7.2.2.3/1 and Voelkl 1993, CA 7.2.2.3/2 no chiral chromatographic methods were applied to obtain information on enantioselective degradation. In the aerobic mineralization study (according to OECD 309) these techniques were applied but no enantioselectivity was observed. But in a water/sediment system the microbial activity may be higher, therefore increasing the chance of chiral degradation. The following studies from literature provide information on this topic. The study of Liu CA 7.2.2.3/5 cannot be used to derive endpoints as the test compounds were incubated with strains known to degrade pythrethroids or adapted sediment, but they provide information on enantioselectivity in biological systems.

Liu W. et al., 2004a
"Isomer Selectivity in Aquatic Toxicity and Biodegradation of Cypermethrin"
(J. Agric Food Chem. 2004, 52, 6233-6238)
2004/1040294
Guidelines: none
GLP: no

Executive Summary

Isomer selectivity of cypermethrin (CP) in its degradation was studied in a degradation experiment with three bacterial degraders, as well as in pond sediment.

In the biodegradation experiment, CP with a nominal concentration of 100 µg L-1 (pH 7) was incubated separately with three known CP degraders (*Vibrio hollisae, Burkholderia picketti, Erwinia carotovora*) in three different population densities. Extraction of CP was performed three times with ethyl acetate at different time intervals. Samples were analyzed by gas-chromatography (GC). Results revealed that the trans diastereomers was degraded preferentially (half-life: 20.6 – 30.0 h) resulting in a relative enrichment of the cis isomers (half-life: 33.5 – 57.7 h). The highest selectivity was observed for *Erwinia carotovora*. The half-life of the insecticidally active enantiomer 1R-cis-αS* was comparatively long (33.6 – 40.3 h), while the unresolved enantiomer pair 1R-trans-αS* + 1S-trans-αR, containing the other active enantiomer, appeared to degrade faster (15.6 – 18.9 h).

In the sediment incubation experiment, CP was applied to pond sediment at a nominal concentration of 1.0 mg kg-1. At different time intervals, CP was extracted three times with acetone : hexane (50:50, v/v) and analyzed by GC. Results revealed a similar selectivity during CP degradation in sediment. Hence, calculated DT50 values were longer for the cis diastereomers (56.8 and 69.3 days) than for the trans diastereomers (39.6 and 33.3 days) The calculated DT50 values of the insecticidally active enantiomer *1R-cis-αS** was among the longest with 74.5 days, whereas the active enantiomer *1R-trans-αS** was probably among the shortest with 40.5 days.

The authors concluded that the overall agreement between the biodegradation and the sediment experiment suggests that the isomer selectivity in CP degradation in sediment was biologically mediated and that isomer selectivity may occur widely in the environment.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test material

Racemically mixed cypermethrin (CP; 98%) and β-CP (86%, enriched in 1R-cis-αS* + 1S-cis-αR and 1S-trans-αR + 1R-trans-αS*) were purchased from Chem Service (West Chester, PA). The isomer-enriched formulations α-CP (96%, enriched in 1R-cis-αS* + 1S-cis-αR) and θ-CP (99%, enriched in 1Rcis-αS*) were provided by FMC (Princeton, PA).

2. Test systems

Bacterial isolates (biodegradation experiment)
Bacterial isolates were obtained by enrichment from sediment previously contaminated with bifenthrin and permethrin, collected from a nursery run-off channel. Three fast-growing bacteria strains were selected as inoculants for the biodegradation experiment.

Sediment sample (degradation experiment)
A sediment sample was collected from a sedimentation pond at a nursery site in Irvine, CA, and contained 0.65% organic carbon and 5% clay. Chemical analysis showed that the sediment was free of CP residues.

B. STUDY DESIGN

1. Experimental conditions

Biodegradation experiment
Isomer selectivity was characterized during degradation of CP by bacterial isolates under aerobic conditions.
A mineral salt solution was adjusted to pH 7.0 with NaOH solution and spiked with CP at a nominal concentration of 100 µg L-1. The initial acetone concentration was 100 µg mL-1. Aliquots were amended with 1.0 mL of enriched bacteria solution. Three CP degraders (Vibrio hollisae, Burkholderia picketti, Erwinia carotovora) were applied separately to reach the following population densities: 8.3 x 107, 2.4 x 108, and 2.5 x 108 colony-forming units per mL. All samples were continuously mixed on a mechanical shaker at room temperature. At different time intervals, triplicate samples were extracted for pesticide residues. Therefore, an aliquot of each sample was three times extracted with 50 mL ethyl acetate for 1 min. The combined extracts were filtered, concentrated and analyzed by gas-chromatography (GC). The overall recovery of the extraction procedure was > 95% for CP or CP isomers.

Degradation in sediment
Changes in the isomer composition due to degradation were further characterized in whole sediment. Wet aliquots from the sediment were immersed with deionized water, spiked with CP and incubated at room temperature (21 ± 2°C). The initial CP concentration was 1.0 mg kg-1. At different time intervals, aliquots of the sediment were removed and analyzed for concentrations of CP diastereomers as well as CP enantiomers. Therefore, the aliquots were extracted three times with acetone : hexane (50:50, v/v) for 60 Minutes. Subsequently, the samples were centrifuged (1300 x g, 20 min), followed by the decantation of the supernatant. The combined extracts were combined, dried with anhydrous sodium sulphate, concentrated, and analyzed by GC. The procedural recovery was > 90%.

2. Stereoisomer separation and analysis

GC methods described in another publication of Liu et al. [LIU, W.P., GAN, J.J. (2004) Separation and analysis of diastereomers and enantiomers of cypermethrin and cyfluthrin by gas chromatography. .J. Agric. Food Chem., 2004, Vol. 52, p. 755-761] were applied to identify CP diastereomers and enantiomers. Separation and analysis was performed using an achiral column for CP diastereomers and on a chiral column for CP enantiomers. The analyses with the achiral column resulted in four peaks, each peak representing two diastereomers. The analyses with the chiral column resulted in six peaks, representing the four cis-isomers of CP in single peaks (separation of enantiomers) and two groups of trans-isomers in two peaks. In both cases, analyses were carried out using an Agilent 6890N GC with electron capture detector (ECD).
Dissipation of CP diastereomers and cis enantiomers were fitted to a first-order decay model to estimate the rate constant k (h-1) and half-life DT50 (h). The fit was generally good, with $r2 \leq 0.91$ for the diastereomers (achiral analysis) and $r2 \leq 0.87$ for the resolved enantiomers (chiral analysis).

II. RESULTS AND DISCUSSION

Biodegradation experiment
CP diastereomers were degraded relatively rapid by the bacterial isolates with the longest half-life of about 58 h. In control samples, CP was relatively stable (< 10% loss after 112 days). In the inoculated samples, a preferentially degradation of the CP trans diastereomers was observed. Half-life values calculated from the results of chiral and achiral analyses ranged from 29.3 to 57.7 h for the cis-isomers of CP and from 15.6 to 30.0 h for the trans-isomers of CP.
The half-life of the insecticidally active enantiomer 1R-cis-αS* was comparatively long (33.6 to 40.3 h), in contrast to the other stereoisomers (29.3 to 39.6 h) for the same degrading bacteria. However, the unresolved enantiomer pair 1R-trans-αS* + 1S-trans-αR (15.6 to 18.9 h), containing the insecticidally active enantiomer, seemed to degrade faster than the enantiomer pair of the other diastereomer (16.4 to 22.9 h).

Degradation in sediment
Dissipation of CP diastereomers or resolved enantiomers followed first order kinetics with $r^2 \geq 0.98$ for the diastereomers and $r2 \geq 0.93$ for the enantiomers. Rate constants and half-lives are given in Table 7.2.2.3-28.

Consistent with the results from the biodegradation experiment, the cis diastereomers were more persistent than the trans diastereomers in the pond sediment. The half-life of 1R-cis-αS* was among the longest with 74.5 days, whereas that for 1R-trans-αS* was probably among the shortest with 40.5 days. The latter could not be clarified due to a lack of separation for the trans diastereomers.

Table 7.2.2.3-28: Half-fife (DT_{50}), and correlation coefficient r^2 for the degradation of cypermethrin diastereomers (determined by achiral GC analysis) and enantiomers (determined by chiral GC analysis) in sediment (according to Liu et al. 2004)

	Diastereomers

[a] Denotes insecticidally active enantiomers.

III. CONCLUSION

The authors concluded that the overall agreement between the biodegradation and the sediment experiment suggests that the isomer selectivity in capermethrin degradation in sediment was biologically mediated and that isomer selectivity may occur widely in the environment.

Report: CA 7.2.2.3/6
Qin S. et al., 2006a
"Enantioselective Degradation and Chiral Stability of Pyrethroids in Soil and Sediment (J. Agric Food Chem. 2006, 61, 5040-5045)
2006/1050993
Guidelines: none
GLP: no

Executive Summary

Field sediment samples were analyzed and long-term laboratory incubation experiments were conducted to better understand the effect of chirality of pyrethroide insecticides (inter alia cypermethrin (CP)) on biodegradation.

Field sediment samples were taken from the Upper Newport Bay – San Diego Creek watershed (CA, USA) in spring and summer of year 2005. Field samples were extracted three consecutive steps with acetone : methylene chloride (50;50, v/v).

Cypermethrin was only detected in field sediment samples collected in spring. Enantioselective degradation was found for these samples. The direction of enantioselectivity appeared to depend on the sampling location and environmental conditions.

Laboratory incubation experiments were conducted under aerobic and anaerobic conditions with samples derived from one soil and one sediment. In addition, the importance of the microbial community for the enantioselective degradation of CP was investigated in sterilized soil and sediment samples. Incubation samples were treated with either 1R-cis-αS-CP or 1S-cis-αR-CP and extracted after different time intervals by using a mixture of hexane and acetone (50:50, v/v). Analyses were performed with chiral and achiral gas-chromatography.

Half-life values of CP ranged from 53 to 154 days. Enantioselective degradation of cypermethrin occurred in non-sterilized soils under aerobic and under anaerobic incubation. Under both conditions, enantiomer 1R-cis-αS-CP was degraded more rapid than the 1S-cisαR-CP enantiomer. Results from the incubation experiment with sterilized soil and sediment suggested that the enantioselective degradation of CP was driven by microbial transformation.

I. MATERIAL AND METHODS

A. MATERIALS

1. Test material

An analytical standard of racemic cypermethrin (CP; 98%) purchased from Chem Service (West Chester, PA, USA) was used in this study. The isomers 1R-cis-αS-CP and 1S-cis-αR-CP were isolated by using a chiral high performance liquid chromatography (HPLC) column.

2. Test sites

Field sediment samples
Field sediment samples originated from the Upper Newport Bay – San Diego Creek watershed (CA, USA).

Sediment samples for laboratory studies
The study was performed with samples (0-10 cm) of a sandy loam soil (Arlington soil taken from a turfgrass plot at the Agricultural Experiment Station near the University of California, Riverside campus; 67% sand, 24% silt, 9% clay, 0.82% organic matter, pH 6.7), and of a sediment (sediment from San Diego Creek in Irvine, CA; 20% sand, 46% silt, 34% clay, 1.09% organic matter, pH 7.9).

B. STUDY DESIGN

1. Sampling and analysis

Field sediment samples
Field sediment samples were taken in the Upper Newport Bay – San Diego Creek watershed (CA, USA) based on accessibility and land use. Sampling was performed in 2005, one sampling in spring after the rainy season and one sampling in summer in the dry season. Samples of 100 g were homogenized, centrifuged, and the supernatant was decanted.

Aliquots of the sediment samples were mixed with anhydrous sodium sulphate to remove the excess water and extracted by three consecutive steps with acetone : methylene chloride (50;50, v/v) and sonication. After filtration, concentration, and several clean-up steps, samples were analyzed by gas-chromatography (GC).

Sediment samples for laboratory studies
Prior to the experiments, soil and sediment samples were air-dried for 24 h at room temperature, homogenized, and passed through a 2 mm sieve.

2 x 18 aliquots of 10 g of each, soil and sediment, were weight into glass vials. The soil moisture was adjusted to 60% of field holding capacity. For the sediment, around 6 mL of deionized water was added to form a 0.5 cm water layer. In each case, one sample set was incubated under aerobic and one under anaerobic conditions. An additional set of samples was prepared and sterilized by autoclavation to test whether enantioselective degradation was microbially driven. (The respective samples were autoclaved twice at 121°C for 60 min, with a 24 h interval in between.)
The two investigated CP enantiomers (1S-cis-αR-CP and 1R-cis-αS-CP) were applied individually on soil and sediment samples with an application rate of 1 mg kg-1. All spiked samples were incubated at room temperature (20 ± 1°C). Three replicate samples were removed at different time intervals, mixed with anhydrous sodium sulphate, and three-fold extracted with hexane : acetone (50:50, v/v) on a mechanical shaker. Subsequently, samples were centrifuged, concentrated, and analyzed by GC. Preliminary experiments revealed extraction recoveries of > 90%. Samples were stored at -20°C prior to analysis.

Analyses of field sediment samples as well as samples from the incubation experiment were performed on an Agilent 6890N GC system (Palo Alto, CA, USA) with an electron capture detector using either a non-chiral selective column or an enantioselective column.

II. RESULTS AND DISCUSSION

Findings

Field sediment samples

Cypermethrin was only detectable in the field sediment samples collected in spring from the Upper Newport Bay – San Diego Creek watershed. Sediment extracts were analyzed on an enantioselective column and the peak area of the separated peaks was used to calculate the relative fraction of the resolved stereoisomers. The column allowed to obtain single peaks for the four cis-isomers of CP and two peaks for the four trans-isomers of CP. Enantioselective degradation was found for all samples. The direction of enantioselectivity appeared to depend on the sampling location and environmental conditions.

Laboratory degradation experiments

For all treatments, data fitted well to the first order decay model (r^2 = 0.87-1.00). Cypermethrin enantiomers exhibited half-lives ranging from 53 to 154 days. The authors attributed the long half-lives compared to other studies to the comparatively low organic carbon content in the soil and the sediment (0.8 and 1.1% organic matter).

Enantioselective degradation of cypermethrin occurred in non-sterilized soils under aerobic and under anaerobic incubation. Half-lives under aerobic incubation were 71 (*1S-cis-αR-CP*) and 63 days (*1R-cis-αS-CP*) in soil and 85 (*1S-cis-αR-CP*) and 53 days (*1R-cis-αS-CP*) in sediment, respectively. Under anaerobic conditions, half-lives were higher with 120 (1S-cis-αR-CP) and 71 days (*1R-cis-αS-CP*) in soil and 154 (*1S-cis-αR-CP*) and 136 days (*1R-cis-αS-CP*) in sediment, respectively. Hence, the enantiomer *1R-cis-αS-CP* was degraded more rapid than the 1S-cis-αR-CP enantiomer in non-sterilized soil/sediment samples. This difference was significant at α = 0.05.
In sterilized soil/sediment samples no enantioselective degradation was observed. Half-lives under sterilized conditions were 116 (*1S-cis-αR-CP*) and 120 days (*1R-cis-αS-CP*) in soil and120 (*1S-cis-αR-CP*) and 122 days (*1R-cis-αS-CP*) in sediment. The results suggest that the enantioselective degradation of CP was driven by microbial transformation.

The degradation of CP was in part slower under anaerobic conditions than under sterilized conditions. As photodegradation is known to be important for CP degradation, the authors attributed the slower degradation under anaerobic conditions partly to the fact that photodegradation was completely inhibited under anaerobic conditions, as the samples were kept in the nitrogen filled chamber.

III. CONCLUSION

The study demonstrates that enantioselective degradation commonly occurred for cypermethrin under both field and laboratory conditions and that the selectivity was attributed to microbial transformations. However, the direction and degree of enantioselectivity were not always predictable. It appears that both stereochemistry of the chiral compound and environmental conditions influenced the direction and rate of enantioselective degradation.

Summary of maximum occurrences for alpha-cypermethrin metabolites in aquatic laboratory studies

Table 7.2.2.3-29: Maximum occurrences of the metabolites of DCVA, 3-PBA, and 3-PBAld in aquatic laboratory studies

Metabolite	BASF DocID	Study type	Test system	Max. occurrence [%]
DCVA	1993/7002022 (AL-630-012)	Water/sediment	Rhine river	38.9 [a]
			Judenweiher pond	66.6 [a]
3-PBA	1993/7002021 (AL-630-011)	Water/sediment	Rhine river	21.7 [a]
			Judenweiher pond	23.1 [a]
3-PBAld	1993/7001988 (AL-322-002)	Hydrolysis	pH 7, 50°C	21.6[b]
	2001/7001562 (AL-324-003)	Aqueous photolysis	pH 5	15.9

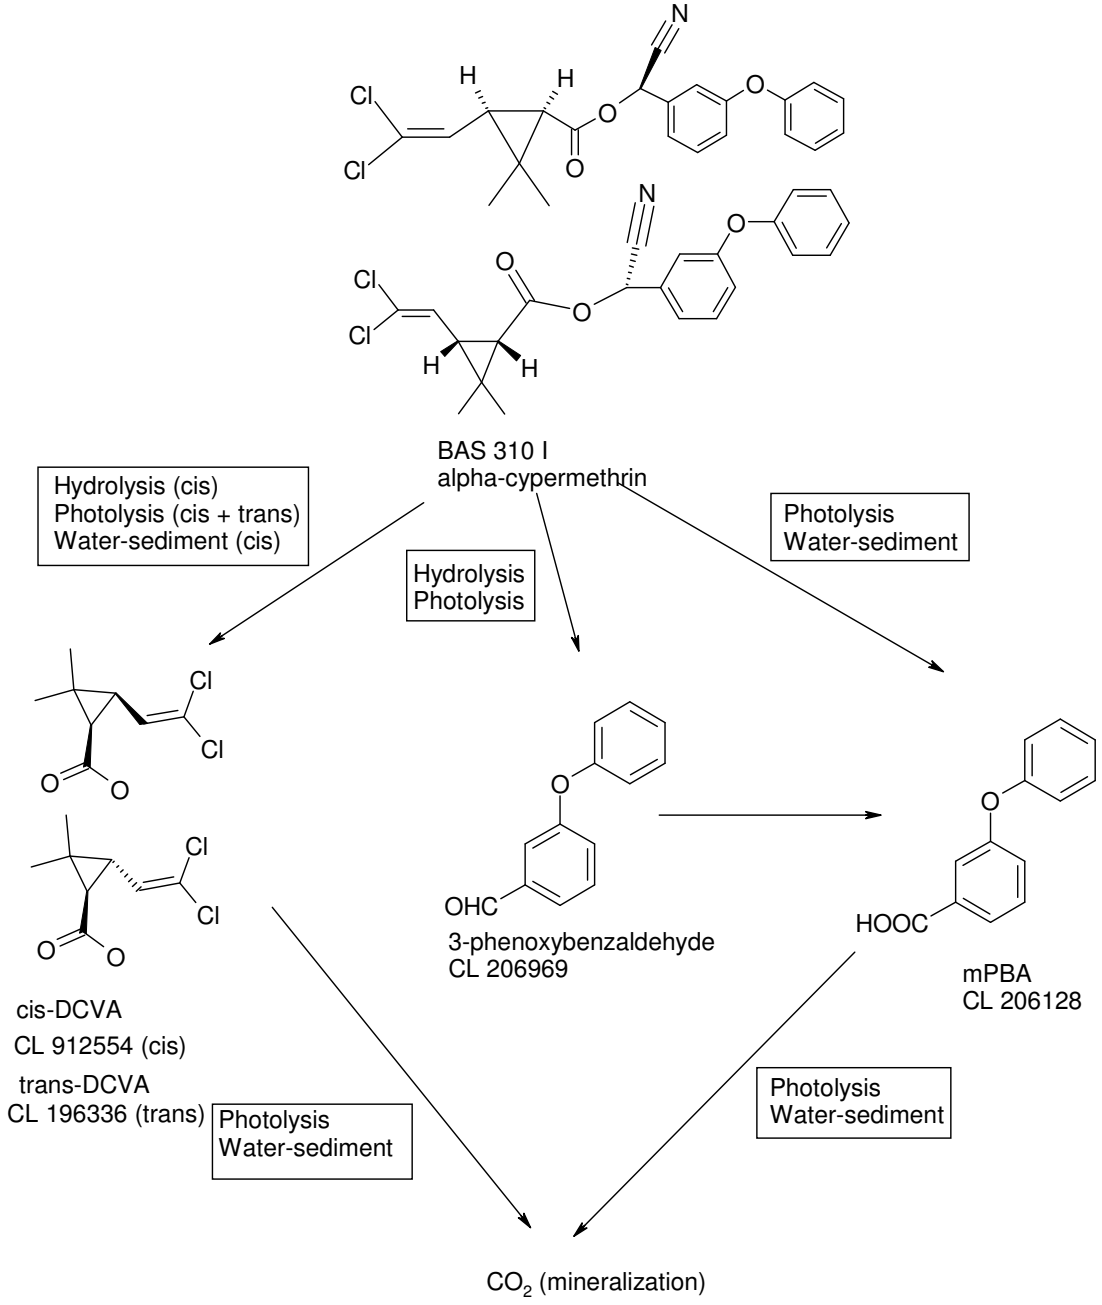
[a] Sum of water and sediment phase; mean of two replicates

[b] not relevant for risk assessment

CA 7.2.2.4 Irradiated water/sediment study

No irradiated water/sediment study was performed. Alpha-cypermethrin dissipates rapidly from the water phase due to its high sorption to sediment. Therefore light may have a limited effect on degradation, though the aqueous photolysis study show enhanced degradation of the parent compound under sunlight.

Figure 7.2.2.4-1: Route of degradation of alpha-cypermethrin in water



CA 7.2.3 Degradation in the saturated zone

Due to its low leaching potential, alpha-cypermethrin is not expected to reach deeper soil layers or saturated zones. Therefore, investigations on the degradation in the saturated zone are considered to be not necessary.

CA 7.3 Fate and behaviour in air

CA 7.3.1 Route and rate of degradation in air

Table 7.3.1-1: List of degradation studies in air performed with alpha-cypermethrin

DocID	Parent compound	Estimated parameters	Remark
Craig, 1999	Alpha-cypermethrin	Henry's law constant	
Grayson et al., 1982	Alpha-cypermethrin	Vapour pressure	
AL-324-002	Alpha-cypermethrin	Half-live values	G. Mangels 1995

The studies in Table 7.3.1-1 will no longer be used. Vapour pressure was determined by Kroehl (2014 a):

3.8 10^{-7} Pa at 20°C

and the Henry constant was calculated by Kroehl (2014 i) to be:

H = 5.3 * 10^{-2} Pa m^3 / mol

Recalculation with AOP v1.92 (Hydroxyl radicals) and AOP v1.91 (Ozone reaction)

The degradation rates for reactions of alpha-cypermethrin with OH-radicals and ozone in the atmosphere were calculated using the AOPWIN program based on ATKINSON's increment method. The SMILE notation used for alpha-cypermethrin in AOPWIN was:

CC1([C@H]([C@H]1C(=O)O[C@H](C#N)c2cccc(c2)Oc3ccccc3)C=C(Cl)Cl)C

The atmospheric degradation half-life of the substance via this reaction route was estimated to be $t_{1/2}$ = 0.499 d (5.99 h).

Based on the results of the atmospheric degradation half-life of alpha-cypermethrin ($t_{1/2}$ = 0.5 d), it can be concluded that the substance will be rapidly degraded by photochemical processes in the troposphere. Hence, due to the rapid degradation in air, it can be concluded that there is no risk of long-range transport of alpha-cypermethrin.

CA 7.3.2 Transport via air

Alpha-cypermethrin has a very low volatilization potential and is degraded very fast by photochemical processes. Consequently, there is no risk of long-range transport of alpha-cypermethrin.

CA 7.3.3 Local and global effects

No effects are expected since transport via air is very unlikely (for details see above).

CA 7.4 Definition of the residue

CA 7.4.1 Definition of the residue for risk assessment

According to the results presented in M-CA 7.1 – 7.3 the following compounds have to be considered for the environmental risk assessment:

Soil:
Alpha-cypermethrin and its aerobic soil metabolites DCVA, 3-PBA and M310I017 (Reg No. 6002320, hydroxy-alpha-cypermethrin)

The metabolites DCVA and 3-PBA were tested for ecotoxicological effects. In addition, it can be assumed that in long-term studies with alpha-cypermethrin, its metabolites will form and are thus included in the testing. Based on the obtained results it can be concluded that the risk of metabolites for soil organisms is low.

Groundwater:
Alpha-cypermethrin, its aerobic soil metabolites DCVA, 3-PBA and M310I017 (Reg No. 6002320, hydroxy-alpha-cypermethrin)

Based on the high adsorption and/or the fast degradation rates in soil, neither the parent molecule nor one of its metabolites poses any risk of leaching to groundwater. The predicted annual leachate concentrations of alpha-cypermethrin and all soil metabolites were below 0.001 µg L^{-1}.

Surface Water:
Alpha-cypermethrin, DCVA and 3-PBA, 3-PBAldehyde and M310I017 (Reg No. 6002320, hydroxy-alpha-cypermethrin)

The aquatic toxicity of DCVA, 3-PBA and 3-PBAldehyde was tested and was found to be orders of magnitude lower for the most sensitive species than parent. For M310I017 the concentrations in surface water at FOCUS step 2 are already < 0.001 µg/L and thus not relevant. Therefore, sufficient margins of safety were achieved with FOCUS surface water step 1-2 calculations and it is concluded that the risk of metabolites for aquatic organisms is low.

Sediment:
Alpha-cypermethrin, DCVA, 3-PBA, 3-PBAldehyd and M310I017 (Reg. No. 6002320)

Due to the low toxicity to aquatic arthropods, sediment toxicity testing of metabolites was not triggered. Thus, it is concluded that the risk of metabolites for sediment organisms is low.

Air:
Alpha-cypermethrin

No volatile metabolite was detected.

CA 7.4.2 Definition of the residue for monitoring

According to the results of the risk assessment the following compounds should be considered for environmental monitoring:

Soil:	Alpha-cypermethrin, DCVA and 3-PBA
Ground Water:	Alpha-cypermethrin DCVA and 3-PBA
Surface Water:	Alpha-cypermethrin DCVA and 3-PBA
Sediment:	Alpha-cypermethrin DCVA and 3-PBA
Air:	Alpha-cypermethrin (parent only)

CA 7.5 Monitoring data

According to the knowledge of the applicant, there are currently no published environmental monitoring data available for alpha-cypermethrin or its metabolites, which would provide knowledge on the environmental behaviour not covered by this dossier.

During literature search a few publications were found dealing with environmental monitoring of various pesticides in surface water, groundwater and/or sediment inside and outside of the EU (e.g. US, Argentina, Vietnam, Canada, Greece, Portugal) mentioning also cypermethrin or alpha-cypermethrin. The results showed that alpha-cypermethrin could be detected in local areas characterized by intensive insecticide use during the spraying season but also due to application of alpha-cypermethrin outside agriculture (biocidal use). Frequencies of detections as well as measured concentrations were usually very low.

Monitoring data of alpha-cypermethrin from within EU countries have been evaluated during the review process of the Water Framework Directive (WFD) Priority Substances list. Monitoring data are available from two countries, from France (2000 to 2007) and from Finland (only 2005). In sum 18695 measurements are available from river waters, however only two of them were > LOQ. A summary of the surface water monitoring data is given in the WFD alpha-cypermethrin factsheet (http://www.priority.substances.wfd.oieau.fr/pdf/alpha-Cypermethrin_%28aka_alphamethrin%29.pdf).
With the EU directive 2013/39/EU cypermethrin has been included in the list of priority substances in the field of water policy. Therefore, surface water monitoring within the monitoring program of the Water Framework Directive will include measurements of alpha-cypermethrin from Dec 2018 onwards in the EU.

[redacted] 2009a
BAS 310 I - Acute toxicity in the Zebra finch (Taeniopygia guttata) after single oral administration (LD50)
2009/1114317
Guidelines: EPA 540/9-82-024, EPA 540/9-85-007, EPA 850.2100, EPA 712-C-96-139, EPA 71-1
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

An avian acute oral toxicity test with the active substance BAS 310 I was conducted. The objective of the study was to evaluate the acute toxicity of the substance in Zebra finches (*Taeniopygia guttata*) and to determine the oral LD_{50} and the no observed effect level (NOEL).

The test substance was administered via a single oral dose of 500, 1000 or 2000 mg a.s./kg body weight to groups of 2-month old Zebra finches. Ten birds (5 males and 5 females) were used in each test substance group. The doses were administered in aqueous carboxy methyl cellulose (CMC). Birds that have been fasted for about 20 to 22 hours were administered the test substance. Birds of all groups received food and water *ad libitum* throughout the test. The test was terminated after 14 days.

All groups were observed for mortality, signs of clinical toxicity, impact on food consumption and body weight for 14 consecutive days post dosing.

No mortality occurred throughout the duration of the study in the control and at the dose rate of 500 mg a.s./kg body weight (b.w.). The mortality observed in dose rate of 1000 mg a.s./kg b.w. was 40% and at the highest dose rate of 2000 mg a.s./kg b.w. 70%. No substance-related impairment of feed uptake in comparison to the control was observed in any of the dose groups. No substance-related impairment of food uptake in comparison to the control was observed in any of the dose groups. No statistically significant (Dunnett test) substance-related reduction of the body weights in the male and female birds was observed on day 7 and at day 14 (sacrifice) in any of the dose groups compared to the control and thus the body weight development was not impaired compared to the control group. All birds were examined macroscopically (post-mortem) after study termination. No abnormalities were detected in surviving birds after sacrifice. One female bird in the dose group receiving 500 mg/kg body weight head a lesion at the head most likely caused by fighting.

In an acute oral toxicity test with the Zebra finch (*Taeniopygia guttata*), the LD_{50} of BAS 310 I was found to be 1360 mg a.s./kg b.w. The NOEL was < 500 mg a.s./kg b.w.

I. MATERIAL AND METHODS

Test item:	BAS 310 I (Reg. No. 4078193), batch no. COD 000595, purity: 99.2% (tolerance ± 1.0%).
Test species:	Zebra finches (*Taeniopygia guttata*), visually indistinguishable from wild birds; adults, age: approx. 2 month (before beginning of first egg-laying period); supplier: Kölle-Zoo, Ludwigshafen, Germany.
Test design:	Birds were administered single doses of 500, 1000 or 2000 mg a.s./kg body weight of the test substance BAS 310 I in 0.5% aqueous carboxy methyl cellulose by gavage into the crop in a total amount of 10 g preparation per kg body weight; 5 males and 5 females per dose group were used; observation period of 14 days; assessment of mortality and clinical signs was carried out four times on day of dosing and daily thereafter; assessment of body weight was carried out on the day of dosing and on day 7 and 14; mean food consumption (g/bird/day) was calculated from the daily food consumption per cage separately for male and female birds after dosing. Gross-pathological post-mortem examinations of all birds at study termination on day 14 after dosing.
Endpoints:	Mortality, clinical signs, feed consumption, body weight (b.w.), and gross-pathological examinations were conducted on all birds sacrificed at the termination of the definitive test. Calculation of LD_{50} and NOEL.
Test concentrations:	0 (Control), 500, 1000, and 2000 mg a.s./kg body weight (nominal).
Test conditions:	Birds fasted for about 20 h to 22 h before administration of the test substance; temperature: 20.7 °C - 23.6 °C; relative humidity: 45% - 70% (limits); photoperiod: 8 hours light : 16 hours dark, light intensity: 41 lux - 132 lux.
Analytics:	The test substance concentrations were analyzed using HPLC.
Statistics:	Descriptive statistics, Probit analyses according to Finney's method for LD50; Dunnett test for body weight data.

II. RESULTS AND DISCUSSION

Analytical measurements: The results of the analytical verification of the test substance concentration in the diet were within a range of 100% to 102% of the nominal concentrations during the test. The biological results are therefore based on the nominal values.

Biological results: No mortality occurred throughout the duration of the study in the control and at the dose rate of 500 mg a.s./kg body weight (b.w.). The mortality observed in dose rate of 1000 mg a.s./kg b.w. was 40% and at the highest dose rate of 2000 mg a.s./kg b.w. 70%. No toxic signs were observed in the control and in all test substance concentrations. No substance-related impairment of food uptake in comparison to the control was observed in any of the dose groups. No statistically significant (Dunnett test) substance-related reduction of the body weights in the male and female birds was observed on day 7 and at day 14 (sacrifice) in any of the dose groups compared to the control and thus the body weight development was not impaired compared to the control group. All birds were examined macroscopically (post-mortem) after study termination. No abnormalities were detected in surviving birds after sacrifice. One female bird in the dose group receiving 500 mg/kg body weight head a lesion at the head most likely caused by fighting. The relevant data and endpoints of the study are summarized in the table below

Acute toxicity of BAS 310 I to Zebra finch (*Taeniopygia guttata*)

	Dose rate [mg/kg b.w.]			
	0 (control)	**500**	**1000**	**2000**
Number of dead birds	0	0	4	7
Dead birds Percentage [%]	0	0	40	70 [1)]

Endpoints	**Dose [mg a.s./kg b.w.]**
Highest dose causing no substance-related mortality	500
LD_{50} (14 d)	1360
NOEL	< 500

b.w. = body weight

1) Erroneously one male bird was assigned to the cage with female birds.

2) Unexpectedly the test item caused mortality in the zebra finch in doses < 2000 mg/kg body weight. In consequence the requirement of the test guideline (EPA) to perform the test with 5 doses plus a control group in case of toxicity was not met. However, a clear dose-effect relationship could be estabilshed with the 3 doses tested in this study with partial mortality in 2 dose groups, one below and one above the LD50. Therefore the calculation of the LD50 does provide reliable and valid results. The deviation had thus no influence on the LD50 derived in this study. However, no "No observed effect level" (NOEL) could be established.

CONCLUSION

In an acute oral toxicity test with the Zebra finch (*Taeniopygia guttata*), the LD_{50} of BAS 310 I was found to be 1360 mg a.s./kg b.w. The NOEL was < 500 mg a.s./kg b.w.

CA 8.1.1.2 Short-term dietary toxicity to birds

No new study available.

Alphacypermethrin (BAS 310I) Assessment to Determine the Effects on Reproduction in Northern Bobwhite (*Colinus virginianus*). Vol. 1-2-3
Huntingdon Life Sciences. Report No.: CYD 630/003917; BASF Report No.: ETX-00-183.
AL-534-002
Guidelines: U.S. EPA Guideline Number 71-4; USEPA OPPTS 850.2300; and OECD 206.
GLP: Yes (certified by the Department of Health of the Government of the United Kingdom)

Executive Summary

Three treated groups of 20 replicates, one male and one female per replicate, were offered test diet containing 50, 150,450 ppm ai Alphacypennethrin over a period of 22 weeks (for 10 weeks prior to the start of egg production and during 12 weeks of egg production). A similar sized control group was given untreated diet only.

From the beginning of Week 11, eggs were incubated to hatching and chicks observed over fourteenday periods. Observations including mortality, clinical signs, bodyweight and food consumption were made during the study. Reproductive success was assessed by examining the following parameters: Eggs laid, eggs damaged, egg shell thickness, embryonic viability, and chick survival and growth.

Dietary administration of Alphacypermethrin to the Northern Bobwhite at dose concentrations up to 150 ppm a.s. had no effect on the health or reproductive performance of adult birds or on the health and growth of their chicks.

At 450 ppm a.s., group mean male adult bodyweights were significantly lower than the controls at termination of the study (p<0.05) and chick survival was reduced compared with the controls (p<0.05).

Food consumption of adult birds was shown to be statistically higher at 150 and 450 ppm a.s. compared with the control (p<0.05). However, this was considered to be of no adverse biological significance.

The NOEC in the avian reproduction study with Northern Bobwhite was determined to be 150 mg a.s./kg diet.

I. MATERIAL AND METHODS

Test item:	BAS 310 I: Technical grade Alphacypermethrin (also known as AC 900049); Lot number AC 12395-18; Purity 96.1% (Purity adjusted 100% while making the test diet).
Test species:	Norther Bobwhite (*Colinus virginianus*) Origin: Monkfield Nutrition, Royston, England.
Test design:	Adult birds were housed as pairs (one male and one female) in polythene coated steel wire cages. The adult birds were maintained on an 7-hour light : 17-hour dark photoperiod during acclimatisation and during the first five weeks. At the start of Week 6, the light portion of the photoperiod was increased to 16 hours light : 8 hours dark. The photoperiod remained at this interval until termination of the adult portion of the study. The total time on the treated diet was 22 weeks.
Endpoints:	Adults were observed daily for mortality, abnormal behaviour and signs of toxicity. Food consumption was monitored. Eggs were collected daily from the onset of egg production and set weekly for incubation. In addition, every other week throughout the egg laying period, eggs laid on the first day of the week were collected from every replicate (when available) for egg shell thickness measurements. During incubation, the eggs were candled to check for embryo development. All hatchlings were observed after hatching for 14 days to assess hatchling survival.
Test concentrations:	0, 50, 150, 450 mg a.s./kg diet. Dietary concentrations tested were 0 (Control), 50, 150, 450 ppm ai in the diet.
Test conditions:	Adult bobwhite quail study room: mean daily maximum temperature 22 C, mean daily minimum 20 C; mean daily relative humidity: 44%; photoperiod: 7 hours light (week 1 – 5), lengthened the photoperiod to 16 hours (week 6 – termination). Incubation of eggs: placed in a commercial storage facility: temperature: 16°C. Eggs were set every other week for incubation: temperature: 37.5°C, relative humidity: 55%; after 21 days transferred to the hatcher: temperature: 37.5°C. Juveniles: (F1 generation): Mean maximum room temperature: 25 – 29°C, mean minimum room temperature 23 - 25°C; relative humidity: 38 – 40%.
Analytics:	Alphacypermethrin in the test diets were analytically verified during the test.

II. RESULTS AND DISCUSSION

Analytical measurements:

Samples of the test diets presented to the adult birds during the test averaged 96% (50 mg a.s./kg diet), 99% (150 mg a.s./kg diet), 100% (450 mg a.s./kg diet) of nominal. No Alphacypermethrin was detected (limit of detection <1.125 ppm) in the control diet.

Biological results:

The effect of the various treatments on the reproductive parameters evaluated during the test are summarised in the Table 8.1.1.3-1.

Table 8.1.1.3-1 Effects of Alphacypermethrin (BAS 310 I) on the reproduction of Northern Bobwhite (*Colinus virginianus*).

Parameters	mg a.s./kg diet			
	Control	50	150	450
Adult				
Initial (week -0) mean bodyweight of male (g)	190.2	188.6	195.0	196.7
Terminal (week - 22) mean bodyweight of male (g)	209.1	208.1	206.7	202.4*
Initial (week -0) mean bodyweight female (g)	190.8	193.3	187.3	191.1
Terminal (week - 22) mean bodyweight of female (g)	225.3	230.6	214.0	227.4
Mean food consumption (g/bird/day)	19	21	21≠	21≠
Non treatment-related mortalities (all female)	1	2	0	3
Treatment-related mortalities	0	0	0	0
Treatment-related clinical signs	0	0	0	0
Treatment-`related macroscopic *post mortem* observation	0	0	0	0
Reproductive				
Number of eggs laid	1014	1079	1025	1163
Eggs laid per female	53.4	55.2	51.3	60.5
Cracked eggs	56	36	42	35

14-day old survivors	750	729	762	802
14-day old survivors of eggs laid (%)	74	68	74	69
14-day old survivors of normal hatchlings (%)	98	97	98	89*
14-day old survivors per female	39.5	37.3	38.1	41.7
Chick bodyweight at hatching (g)	6.9	7.1	7.2	6.9
Chick bodyweight at 14 days (g)	21	20	21	20

* parameter statistically lower than control (p<0.05)
≠ parameter statistically higher than control (p<0.05)

Dietary administration of Alphacypermethrin to the Northern Bobwhite at dose concentrations up to 150 ppm a.s. had no effect on the health or reproductive performance of adult birds or on the health and growth of their chicks.

At 450 ppm a.s., group mean male adult bodyweights were significantly lower than the controls at termination of the study (p<0.05) and chick survival was reduced compared with the controls (p<0.05).

Food consumption of adult birds was shown to be statistically higher at 150 and 450 ppm a.s. compared with the control (p<0.05). However, this was considered to be of no adverse biological significance.

Conclusion

The NOEC in the avian reproduction study with Northern Bobwhite was determined to be 150 mg a.s./kg diet.

CA 8.1.2 Effects on terrestrial vertebrates other than birds

CA 8.1.2.1 Acute oral toxicity to mammals

No new study available.

CA 8.1.2.2 Long-term and reproductive toxicity to mammals

No new study available.

CA 8.1.3 Effects of active substance bioconcentration in prey of birds and mammals

Bioaccumulation in terrestrial food chains is addressed in Chapter CP 10.1.

CA 8.1.4 Effects on terrestrial vertebrate wildlife (birds, mammals, reptiles and amphibians)

According to the revised data requirements under regulation 1107/2009 (Commission Regulations (EU) 283/2013 and 284/2013 for the active ingredient and the plant protection products, respectively), the risk to amphibians and reptiles shall be addressed. Nevertheless, unlike birds and mammals, toxicity tests for amphibian and reptile species are not requested. In the EU there is no guidance or validated regulatory protocols yet available neither on the type of regulatory testing necessary nor on how to conduct a risk assessment for amphibians and reptiles. In the case of alpha-cypermethrin, there are some studies in the literature on the toxicity of this active ingredient on aquatic life-stages of amphibians. For reptiles, no toxicity data of alpha-cypermethrin are available.

According to the new aquatic guidance document (EFSA, 2013) amphibians should be included in the aquatic and terrestrial risk assessment. In absence of GLP studies the assessment should be based on any existing relevant information (testing of amphibians is not recommended in the first instance, due to animal welfare reasons and the absence of standard guidelines for amphibian testing). With regard to the aquatic risk assessment several data analyses indicate that the risk assessment for aquatic organisms (and fish in particular) covers the risk assessment for aquatic phases of amphibians (Fryday and Thompson, 2012; Weltje et al., 2013). The review by Weltje et al. (2013) includes acute and chronic data for amphibians and alpha-cypermethrin (Yu et al., 2013 and Greulich and Pflugmacher, 2003); both in acute and chronic studies amphibians were less sensitive than fish. Based on these extensive data reviews it can be concluded that the acute and chronic risk to aquatic life-stages of amphibians is covered by the currently requested and conducted risk assessment for fish (for more details see chapter 10.2).

Regulatory ecotoxicological information on terrestrial amphibians is scarce in general. However, in the few cases where terrestrial stages of amphibians were exposed orally in the same study as birds and mammals the general pattern is that amphibians are less sensitive than the latter two taxa (see Table 13 in Fryday and Thompson, 2012). This suggests that the quantitative risk assessment done for birds and mammals would be conservative for the terrestrial phase of amphibians.

In the case of reptiles there is even less information available than for amphibians (see the review by Fryday and Thompson, 2009). The risk from dietary exposure can be assumed to be lower for reptiles than for birds and mammals due to the lower food intake rate (FIR) (Fryday and Thompson 2009). This is because reptiles are poikilotherm (i.e., do not maintain a constant body temperature) and as a result feeding activity will peak at warm days and will be zero during hibernation or at cold days. In contrast, birds and mammals will have to maintain a constant body temperature and, hence, will need to feed every day (Fryday & Thompson 2009).

CA 8.1.5 Endocrine disrupting properties

Overall there is no convincing evidence for a potential of endocrine activity of alpha-cypermethrin *in vivo* up to dose levels not also causing significant systemic toxicity. A potential non-specific testicular toxicity has been investigated for alpha-cypermethrin in rats (BASF DocID 2014/1275120). This study showed no effects on sex organ weight parameters, no effect on sperm parameters and no indication of any effect on androgen receptor density. Therefore, it is appropriate to conclude that alpha-cypermethrin is neither endocrine active nor does it show testicular toxicity up to maximal tolerable dose levels. Further details on the rat testicular toxicity study and endocrine potential of alpha-cypermethrin can be found in section M-CA 5.8.3.
Similarly, in the available long-term bird and fish studies there were no signs of endocrine potential of alpha-cypermethrin.

CA 8.2 Effects on aquatic organisms

Since Annex I inclusion of alpha-cypermethrin (BAS 310 I), new toxicity studies on the active substance and its major metabolites have been performed and as a result there are new endpoints which are now used in the aquatic risk assessment. Summaries of these new studies are provided below. For completeness this includes some older studies, which have not been submitted during the previous Annex I inclusion process (e.g. because there is no respective data requirement in the EU). In addition, summaries are provided for peer-reviewed scientific literature that was considered to be of relevance for the aquatic risk assessment of alpha-cypermethrin.

Details on the EU agreed studies which have been already evaluated within the Annex I inclusion of alpha-cypermethrin are provided in the EU Review documents of alpha-cypermethrin (Monograph, Vol. 3, Annex B.8, September 1999; Addendum to the Monograph, Vol. 3, Annex B.9, July 2003; EU Review Report (SANCO/4335/2000-final), February 2004).

For better transparency and traceability of the active substance history, the results of all studies are summarized in Table 8.2-1 and Table 8.2-2.

Full references used within the following chapters are given at the end MCA 8.2. Document N3 contains structures and synonyms for all metabolites.

Bold figures: Where several endpoints are available for the same group or where several endpoints are available for one study based on different effect parameters (*e.g.* for algae and macrophytes), only the relevant endpoint(s) is used in the risk assessment presented in chapter 10.2 of the MCP dossier part for Annex I renewal.

Abbreviations: ELS = early life stage; BCF= bioconcentration factor; EAC = ecologically acceptable concentration

* Study has not been submitted during the Annex I inclusion process of alpha-cypermethrin. A study summary is provided below.

** Data derived from relevant peer-reviewed scientific study (for details see chapter 8.2.8 below).

+ Study was performed with the formulation BAS 310 55 I (containing 50.0 g a.s./L, nominally).

++ Study is EU agreed predominantly for the chronic part. However, the acute study is valid as well.

In accordance to the EFSA Aquatic Guidance Document (EFSA, 2013) and OECD guideline 201 (2001) the 72 h endpoints obtained in the 96 h alga studies are considered as relevant endpoint and are presented here.

§ EAC based on effects on macroinvertebrates from a series of studies including mesocosm studies, additional single species testing and population modeling (BASF DocIDs: AL-560-031, AL-560-023, AL-560-056, 2003/1012038, AL-560-054, 2002/1013889 and 2003/1012036).

$ In accordance to the EFSA Aquatic Guidance Document (EFSA 2013) and OECD guidelines 201 (OECD, 2011) and 221 (OECD, 2006), only the EC_{50} values for the more relevant endpoint 'growth rate' (E_rC_{50}) are considered for the risk assessment for aquatic primary producers.

1) Pulse exposure study simulating realistic drift scenario with two peak concentrations at day 0 and day 7 or at day 7 and day 14. No significant effects of the test item were observed up to and including two peak concentrations of 0.3 µg/L alpha-cypermethrin.
2) Study simulating realistic exposure scenario with two peak concentrations of the test item (7 days interval) and subsequent dissipation. No ecologically relevant effects of the test item were observed up to and including two peak concentrations of 0.149 µg/L alpha-cypermethrin.
3) µg/kg dry sediment (spiked sediment study)
4) marine / saltwater species
5) based on frond number and on dry weight
6) At the time of the Annex I inclusion two fish bioconcentration studies were available with cypermethrin and rainbow trout. Since then a bioconcentration study with alpha-cypermethrin and *Cyprinus carpio* has become available and is considered to provide a more relevant BCF value, as the study was conducted with the actual active substance under evaluation.

Table 8.2-2: List of studies and endpoints for aquatic organisms exposed to the major metabolites of alpha-cypermethrin (BAS 310 I)

Organism	Endpoint	Value [µg/L]	Reference (BASF Name / DocID)	EU agreed
Metabolite: DCVA

Bold figures: Where several endpoints are available for the same group or where several endpoints are available for one study based on different effect parameters (*e.g.* for algae/macrophytes), the relevant endpoint is used in the risk assessment presented in chapter 10.2 of the MCP dossier part for Annex I renewal.

* Study has not been submitted during the Annex I inclusion process of alpha-cypermethrin. A study summary is provided below.

** Data derived from relevant peer-reviewed scientific study (for details see chapter 8.2.8 of the MCA dossier for Annex I renewal).

The higher endpoint from the study on *D. magna* (BASF DocID 2001/1017462) is considered as relevant endpoint; the lower endpoint obtained in a second study (BASF DocID CY-570-003) was not used as no analytical verification of test item concentrations was conducted in this study.

+ The higher endpoint from the study on *L. macrochirus* (BASF DocID 2002/1004683) is considered as relevant endpoint; the lower endpoint obtained in the study on *O. mykiss* (BASF DocID CY-570-002) was not used as no analytical verification of test item concentrations was conducted in this study.

§ In accordance with the new EFSA Aquatic Guidance Document (EFSA, 2013) and OECD guideline 201 (2001) only the EC_{50} values determined for the endpoint 'growth rate' (E_rC_{50}) are considered for the risk assessment for algae if both “growth rate” and “biomass” endpoints are available.

$ Concentration in overlying water or in sediment pore water

1) No analytical verification of test item concentrations was conducted.

2) Study was evaluated for Annex I inclusion of cypermethrin (see Monograph, Addenda and EU Review Report).

3) non-GLP study

4) This non-GLP study is of limited design (no analytical verification, only 4 fish per treatment). However, it is considered sufficient to judge on the acute toxicity to fish and the non-relevance of the metabolite.

CA 8.2.1 Acute toxicity to fish

The following (non-GLP) study with rainbow trout (*Salmo gairdneri*) performed with the metabolite 3-phenoxybenzaldehyde (3-PBAld) is of limited design (no analytical verification, only 4 fish per treatment). However, it is considered sufficient to judge on the acute toxicity to fish and the non-relevance of the metabolite. Thus, the study is provided in support of the aquatic risk assessment and has not been evaluated previously on EU level.

Report:	CA 8.2.1/1 [redacted] 1977a The acute toxicity to rainbow trout (Salmo gairdneri) of some compounds involved with the manufacture of pyrethroid insecticide WL 43467 CY-570-001
Guidelines:	none
GLP:	no

Executive Summary

In a static acute laboratory study, juvenile rainbow trout were exposed to nominal concentrations of 2000, 4000, 8000 and 10000 µg 3-phenoxybenzaldehyde/L (3-PBAld) in groups of 4 animals in glass aquaria containing 10 L of water. One aquarium with water served as control. Fish were observed for survival after 24, 48, 72 and 96 hours after start of exposure.

The biological results are based on nominal concentrations. After 96 hours, no mortality was observed in the control whereas 3-PBAld caused 25% mortality at a concentration of 2000 µg/L and 100% mortality was observed in fish exposed to the three highest test item concentrations of 4000, 8000 and 10000 µg/L.

In a static acute toxicity study with rainbow trout, the LC_{50} (96 h) for 3-phenoxybenzaldehyde (3-PBAld) was determined to be > 2000 and < 4000 µg/L (geometric mean: 2830 µg/L), based on nominal concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: 3-phenoxybenzaldehyde (3-PBAld; Reg. No. 4080665).

B. STUDY DESIGN

Test species: Rainbow trout fingerlings, *Salmo gairdneri* (syn. *Oncorhynchus mykiss*); body weight between 1.00 - 2.00 g; supplied by Parkwood Trout Hatcheries, Harrietsham, Kent, U.K.

Test design: Static system (96 hours); 4 fish per aquarium (10 L) and per concentration; loading: less than 1 g fish/L water; assessment of mortality after 24, 48, 72 and 96 h.

Endpoints: LC_{50} (only range could be determined because only a small amount of test compound was available).

Test concentrations: Control, 2000, 4000, 8000 and 10000 µg 3-PBAld/L (nominal).

Test conditions: 10 L glass aquaria, non-chlorinated tap water; temperature 15 - 16°C; pH 8.0 - 8.4; oxygen content > 9.0 mg/L; total hardness: approx. 250 - 270 ppm $CaCO_3$; slight aeration.

Analytics: No analytical verification of test item concentrations was conducted.

Statistics: Geometric mean calculation for determination of LC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: No analytical verification of test item concentrations was conducted.

Biological results: After 96 hours, no mortality was observed in the control whereas 3-PBAld caused 25% mortality at a concentration of 2000 µg/L and 100% mortality was observed in fish exposed to the three highest test item concentrations of 4000, 8000 and 10000 µg/L. The results are summarized in Table 8.2.1-1.

Table 8.2.1-1: Acute toxicity (96 h) of 3-phenoxybenzaldehyde on rainbow trout (*Oncorhynchus mykiss*)

Concentration [µg/L] (nominal)	**Control**	**2000**	**4000**	**8000**	**10000**
Mortality [%]	0	25	100	100	100
Endpoints [µg/L] (nominal)					
LC_{50} (96 h)	> 2000 < 4000 (geometric mean: 2830)				

III. CONCLUSION

In a static acute toxicity study with rainbow trout, the LC_{50} (96 h) for 3-phenoxybenzaldehyde (3-PBAld) was determined to be > 2000 and < 4000 µg/L (geometric mean: 2830 µg/L), based on nominal concentrations.

From the performed literature search the following five peer-reviewed scientific studies investigating the acute toxicity of alpha-cypermethrin to several fish species were considered relevant for the aquatic risk assessment of alpha-cypermethrin. Due to missing analytical measurements in these studies, they were formally classified as being "not reliable" (Reliability Index (RI) 3). For details please see the literature search and evaluation files also provided within the submission for Annex I Renewal. Nevertheless, the studies were well performed and in general agreement with current guidelines for acute fish toxicity testing (e.g. OECD guideline 203). Furthermore, the endpoints derived from these studies are in a range expected from the available acute GLP data for fish and alpha-cypermethrin. Finally, it was considered that for vertebrates it would be preferable to use available data rather than to conduct additional vertebrate testing (animal welfare considerations). Hence, it is considered appropriate to use the results of these studies for a refined acute risk assessment for aquatic vertebrates. The data had not been used or evaluated during the previous Annex I inclusion process and thus, relevant information and results of these studies are described in the following summary.

Report:	CA 8.2.1/2 Shaluei F. et al., 2012a Evaluation of the acute toxicity of Cypermethrin and its effect on behavioral responses of Caspian roach (Rutilus rutilus caspicus) and Silver carp (Hypophthalmicthys molitrix) 2012/1367682

GLP:	no

Report:	CA 8.2.1/6 Yilmaz M., 2005a Acute toxicity of Alpha-Cypermethrin on tilapia (Oreochromis niloticus L.) larvae 2005/1043560
Guidelines:	none
GLP:	no

Executive Summary

The acute toxicity of alpha-cypermethrin to fish was investigated in four 96-hour static laboratory studies on Caspian roach (*Rutilus rutilus caspicus*) juveniles, Silver carp (*Hypophthalmichthys molitrix*) juveniles, adult male guppy (*Poecilia reticulata*) and adults and larvae of Nile tilapia (*Oreochromis niloticus*) and in one 96-hour semi-static laboratory study on Great sturgeon (*Huso huso*) juveniles. In these studies fish were exposed to a solvent control and to 5 – 9 nominal alpha-cypermethrin concentrations ranging from 0.01 to 20 µg a.s./L in groups of 7 to 15 animals in aquaria. Fish were observed for survival and symptoms of toxicity directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.

The biological results of all studies are based on nominal concentrations of the test item. After 96 hours of exposure, in all tests no mortality or toxic effects were observed in the control group.
In all studies, fish mortality increased significantly when the concentration and the time of exposure were increased. The LC_{50} (96 h) values of alpha-cypermethrin derived from these studies were between 0.627 and 9.43 µg a.s./L.
In all performed studies behavioral changes were recorded. Depending on the tested species, behavioral changes manifested at concentrations ≥ 0.5 µg a.s./L for Caspian roach, Silver carp and Great sturgeon or ≥ 8 µg a.s./L for guppy, ≥ 5 µg a.s./L for adult Nile tilapia and ≥ 1.5 µg a.s./L for Nile tilapia larvae.

In one semi-static and four static acute toxicity studies with five different fish species the LC_{50} (96 h) values of alpha-cypermethrin were between 0.627 and 9.43 µg a.s./L, based on nominal concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I; Reg. no.: 4 078 193), technical grade purities: 95% - 98%; for sources please see the respective publications.

B. STUDY DESIGN

Test species:	Caspian roach (*Rutilus rutilus caspicus*): juveniles, mean body weight: 3.5 ± 0.32 g, mean body length: 7.3 ± 0.65 cm; Silver carp (*Hypophthalmichthys molitrix*), juveniles; mean body weight: 40.68 ± 5.87 g, mean body length: 15.34 ± 3.12 cm; both purchased from by Bony Fish Propagation and Rearing Center of Sijeval (Bandar, Torkaman, Gorgan), Iran. Great sturgeon (*Huso huso*): juveniles; mean body weight: 183.20 ± 4.61 g, mean body length: 36.31 ± 1.27 cm; supplied by Shahid Marjani proliferation and culture centre for sturgeon fish, Gorgan, Iran. Guppy (*Poecilia reticulate*): adult males (no information is given on body weight / length / age of fish), supplied by a local breeder in Ankara, Turkey. Nile tilapia (*Oreochromis niloticus*): adults; mean body weight: 25.03 ± 5.35 g, mean body length: 11.05 ± 1.05 cm; supplied by the Fisheries Unit of Fisheries and Aquaculture Department of Ankara University, Ankara, Turkey. Nile tilapia (*Oreochromis niloticus*): larvae, 3 to 4 days old; mean body weight: 0.054 ± 0.001 g, mean body length: 0.79 ± 0.03 cm; supplied by A. Çağlan Karasu Benli of the Faculty of Agriculture, Ankara University, Ankara, Turkey.
Test design:	Static system (96 h) or semi-static system (96 h; with replacement of the test solution every 24 h); 5 - 9 test item concentrations plus a solvent control (acetone), 1 to 3 replicates per treatment with 7 - 15 fish per aquarium; assessment of mortality and sublethal effects directly after start of exposure and 24, 48, 72 and 96 hours after start of exposure.
Endpoints:	LC_{50}, mortality and sub-lethal effects.
Test concentrations:	Caspian roach and Silver carp: solvent control (acetone), 0.01, 0.5, 2, 4, 8 and 16 µg a.s./L. Great sturgeon: solvent control (acetone), 0.5, 1, 2, 4, 6 and 8 µg a.s./L. Guppy: solvent control (acetone), 5, 8, 10, 15 and 20 µg a.s./L. Nile Tilapia, adults: solvent control (acetone), 5, 6, 7, 8 and 10 µg a.s./L. Nile Tilapia, larvae: solvent control (acetone), 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0, 4.5 and 5.0 µg a.s./L.

Test conditions: Caspian roach and Silver carp: 120 L rectangular aquaria, test volume: 100 L; dilution water: dechlorinated tap water; temperature: 19.95 ± 1.5 °C; pH 7.88 ± 0.76; oxygen content: 8.01 ± 0.35 mg/L; hardness: 300 ± 12.25 mg $CaCO_3$/L; constant aeration; no feeding.

Great sturgeon: 500 L fiberglass tank; dilution water: tap water; temperature: 23 ± 1 °C; pH 7.89 ± 0.9; oxygen content: 7.8 ± 0.5 mg/L; hardness: 295 ± 10 mg $CaCO_3$/L; photoperiod: 14 h light : 10 h dark; constant aeration; no feeding.

Guppy: 20 L aquaria; dilution water: well water; temperature: 20 - 25 °C; pH 7.2; oxygen content: 7.5 mg/L; constant aeration; no feeding.

Nile Tilapia, adults: 20 L plastic aquaria, test volume: 20 L; dilution water: tap water; temperature: 24 ± 1 °C; pH 6.8; oxygen content: 6.9 ± 0.2 mg/L; hardness: 31.6 mg $CaCO_3$/L; alkalinity: 32 mg HCO_3/L; conductivity: 0.182 -0.197 mS/cm; constant aeration; no feeding.

Nile Tilapia, larvae: 20 L plastic aquaria, test volume: 20 L; temperature: 23 ± 1 °C; pH 7.2 ± 0.1; oxygen content: 7.6 ± 0.5 mg/L; conductivity: 0.225 ± 0.010 mS/cm.; constant aeration; no feeding.

Analytics: No analytical measurements were carried out.

Statistics: Descriptive statistics; probit analysis for calculation of LC_{50} values.

II. RESULTS AND DISCUSSION

Analytical measurements: No analytical measurements were carried out. The biological results of all studies are based on nominal concentrations of the test item.

Biological results: After 96 hours of exposure, in all tests no mortality or toxic effects were observed in the solvent control groups. In all studies, fish mortality increased significantly when the concentration and the time of exposure were increased.

In the static study with Caspian roach and Silver carp (DocID 2012/1367682) juveniles no mortality was recorded at the lowest applied test concentration of 0.01 µg a.s./L, whereas higher alpha-cypermethrin concentrations caused increased mortality in both test species. After 96 hours all fish were dead at the two highest tested concentrations of 8 and 16 µg a.s./L in the test with both fish species. The 96 h LC_{50} values were determined to be 0.627 g a.s./L for Caspian Roach and 0.917 µg a.s./L for Silver Carp. At concentrations ≥ 0.5 µg a.s./L, both fish species showed abnormal behavioral responses (*i.e.* rapid gill movement, nervous manifestations, erratic swimming, loss of equilibrium and inability to remain upright). The abnormal swimming behavior increased with increasing concentration of alpha-cypermethrin and exposure time.

Based on the results of the semi-static study with Great sturgeon juveniles (DocID 2012/1367683) a 96 h LC_{50} value of 0.952 µg a.s./L was derived for alpha-cypermethrin. Abnormal behavioral responses started 1 hour after dosing (*i.e.* rapid gill movement, nervous manifestations, erratic swimming, loss of equilibrium and inability to remain upright) and were observed in fish at all tested concentrations (*i.e.* at ≥ 0.5 µg a.s./L).

The 96 h LC_{50} value derived from the static study with adult male guppy (DocID 2004/1040654) was 9.43 µg a.s./L (DocID 2004/1040654). The changes in behavioral response started 2 h after dosing. The fish had less activity at 8 µg a.s./L compared with the control group. The behavioral changes manifested themselves starting at alpha-cypermethrin concentration of 8 µg a.s./L. Other changes were loss of balance, respiratory difficulties, become motionless, attempt to breathe from the surface, change of color in abdominal area and enlargement of the eyes.

In the acute study on adult Nile tilapia (DocID 2009/1131342), no mortality occurred in the lowest tested concentration of 5 µg a.s./L whereas 75% mortality was observed at the concentrations of 6.0 and 7.0 µg a.s./L after 96 hours of exposure. The two highest tested concentrations of 8 and 10 µg a.s./L caused 100% mortality after 96 hours of exposure. The 96-h LC_{50} value derived from the study with for Nile tilapia adults was estimated as 5.99 µg a.s./L. In addition, behavioral changes at each alpha-cypermethrin concentration were observed for the individual fish. The changes in behavioral response started 1-2 hours after dosing, depending on the concentration of toxicant. The fish started to display intense activity one hour after exposure. They left themselves to water currents and made sudden movements at a concentration of 6 µg/L. The fish gave response when tapped on the aquaria walls at a toxicant concentration of 7 µg/L. They gave no such response at higher concentrations and made movements such as somersaulting around their own axis.

Exposure of Nile tilapia larvae (DocID 2005/1043560) to alpha-cypermethrin resulted in a LC_{50} of 3.42 µg a.s./L. Changes in behavioral response started 1 - 2 hours after dosing, depending on the concentration of toxicant. The fish started to display intense activity one hour after exposure. They left themselves to water currents and made sudden movements at a concentration of 5 µg/L. The fish gave response when tapped on the aquaria walls at a toxicant concentration of 1 µg/L. They gave no such response at higher concentrations and made movements such as somersaulting around their own axis.

The endpoints obtained in the fish acute toxicity studies are summarized in Table 8.2.1-2.

Table 8.2.1-2: List of endpoints for alpha-cypermethrin derived from acute toxicity studies conducted with for five fish species

Test species, life stage	**96 h LC_{50} [µg a.s./L]**	**Reference** (BASF DocID)
Caspian roach (*Rutilus rutilus caspicus)*, juveniles	0.627 (95% confidence limits: 0.284 - 0.995)	2012/1367682
Silver carp (*Hypophthalmichthys molitrix*), juveniles	0.917 (95% confidence limits: 0.507 - 1.357)	
Great sturgeon (*Huso huso*), juveniles	0.952 (95% confidence limits: 0.693 - 1.242)	2012/1367683
Guppy (*Poecilia reticulata*), adults (male)	9.43 (95% confidence limits: 8.26 - 11.20)	2004/1040654
Nile tilapia (*Oreochromis niloticus*), adults	5.99 (95% confidence limits: 5.40 - 6.51)	2009/1131342
Nile tilapia (*Oreochromis niloticus*), larvae	3.42 (95% confidence limits: 3.11 - 3.73)	2005/1043560

III. CONCLUSION

In one semi-static and four static acute toxicity studies with five different fish species the LC_{50} (96 h) values of alpha-cypermethrin were between 0.627 and 9.43 µg a.s./L, based on nominal concentrations.

CA 8.2.2 Long-term and chronic toxicity to fish

CA 8.2.2.1 Fish early life stage toxicity test

In addition to the standard fish early life stage (ELS) study on *Pimephales promelas* which has already been evaluated during the Annex I inclusion process a new fish ELS study with pulse-dosed exposure on fathead minnow was conducted to generate further data for a risk refinement and to address potential latency of effects. The study has been used in previous EU end-use product registrations, but has not been evaluated on EU level.

Report:	CA 8.2.2.1/1 [redacted] 2009b BAS 310 I - Early life-stage test on the fathead minnow (Pimephales promelas) with pulse dose exposure 2009/1031203
Guidelines:	OECD 210, EPA 72-4 (a), EPA 850.1400, EPA 540/9-86-138
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

The chronic toxicity of alpha-cypermethrin (BAS 310 I) to fathead minnow (*Pimephales promelas*) was evaluated in a 34-day early life-stage test with pulse dose exposure under flow-through conditions. Two exposure peaks spaced by 7 days were applied to each test group. The peak concentrations declined with a half-life of one day. Two different peak concentrations of 0.15 and 0.30 µg a.s./L) were tested and the peaks were applied according to two different time schedules, to cover the most sensitive life stages. Additionally to the 4 test groups with peak exposure scheme, a dilution water control was tested. Hatchability, post-hatch survival rate, signs of toxicity and growth parameters of fathead minnow embryos were assessed at intervals throughout the study.

The results are based on nominal concentrations. The survival was not impaired in any of the concentration groups compared to the control group. The time to hatch and swim-up was similar in all test groups including the control and thus, was not affected by the test substance. No signs of test item-related toxicity or abnormalities could be observed in any of the peak exposure groups. No test item-related ecologically significant effects were observed in any of the peak exposure groups compared to the control. A tendency towards a reduced body weight was observed in test group 4 (-13% in comparison to the control). However, the ecological significance of such a deviation is considered to be low and may be easily caused by very slight deviations in the environmental conditions. *E.g.* the lowest mean body weight in the replicates of the control group (replicate 0B) is 16% lower than the highest mean body weight measured in replicate 0A. Therefore the observed decrease in body weight is not necessarily substance-related.

In an early life stage study applying a realistic pulse dose exposure pattern with two peaks of alpha-cypermethrin, no substance-related effects on fathead minnow (*Pimephales promelas*) were observed at a nominal peak exposure concentration of 0.30 µg a.s./L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I); batch no: COD-000165; purity: 98.8% ± 1%.

B. STUDY DESIGN

Test species: Fathead minnow (*Pimephales promelas*), eggs less than 4 hours old, source: parental from Osage catfisheries Inc., Osage Beach (MO), USA.

Test design: Flow-through system (34 d); two concentrations and two peak scenarios (spaced by 7 days) plus one dilution water control; 4 replicates per treatment with 25 fertilized eggs in each. Eggs and larvae were exposed in cylindrical glass vessels and were transferred into stainless steel aquaria on day 19. The test solution flowed continuously from the mixing tank into an "udder" which splitted the test water into 4 equal parts for the 4 replicate test aquaria. On day 34 fish were sacrificed and body length and weight were determined. Daily assessment of hatch, swim-up, survival, signs of toxicity and abnormalities.

Endpoints: semi-NOEC values based on hatching rate, post-hatch survival, toxic signs, growth rates and time spans to hatch and swim-up.

Test concentrations: Control (dilution water), 4 treatment groups: 0.15 and 0.30 µg a.s./L (nominal peak concentration on day 0 and day 7 and on day 7 and day 14, respectively).

Test conditions: Test vessels: Cylindrical glass vessels: water volume: 1.7 L; stainless steel aquaria (29 x 21 x 22 cm), water volume: 9 L. Dilution water: non-chlorinated, filtered drinking water (diluted with deionized water); temperature: 23.5 - 25 °C; pH 7.7 - 8.0; oxygen content: 4.6 - 8.4 mg/L; total hardness: approx. 96 - 102 mg $CaCO_3$/L; conductivity: 258 - 260 µS; acid capacity: 2.46 - 2.5 mmol/L; light intensity: 187 - 391 lux in the cylindrical glass vessels and 98 - 208 lux in the stainless steel aquaria; photoperiod: 16 hours light : 8 hours dark; flow rates: 7.5 L/hour/ treatment group, 1.9 L/hour/test vessel. Feeding: freshly hatched Artemia nauplii starting at day 7 and commercial fish diet (TetraMin) from day 9 on. Aeration: from day 20 on.

Analytics: Analytical verification of test item concentrations was conducted using a GC-method with MS detection.

Statistics: Descriptive statistics; Dunnett`s test for weight and length data (two-sided; $\alpha = 0.01$; $\alpha = 0.05$), Fisher's exact test for survival data (one-sided; $\alpha = 0.01$; $\alpha = 0.05$), Wilcoxon-test for variability between replicates (one-sided; $\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: The control group was analyzed during the peak exposure dates and was free of contaminations with the test substance on days 0 and 7. However, on day 14 concentrations around the limit of quantification were determined for the control group. It was assumed that this was most likely caused by contamination of the samples. However, the contamination of the control group with the concentrations found was not expected to have any impact on the study results. The analytically determined concentration values of the test item in the test water confirmed that the nominal peak concentrations were reached or even exceeded, while the peak concentrations declined slightly faster than with the intended half-life of one day. Taking into account the properties of the test substance, which is readily adsorbed, the low test concentrations and the difficulties in the analysis, the actual exposure pattern can be regarded as close to the intended exposure scheme. Therefore, the following biological results are based on nominal concentrations.

Biological results: The survival was not impaired in any of the concentration groups compared to the control group. The time to hatch and swim-up was similar in all test groups including the control and thus, was not affected by the test substance. No signs of test item-related toxicity or abnormalities could be observed in any of the peak exposure groups. No test item-related ecologically significant effects were observed in any of the peak exposure groups compared to the control. A tendency towards a reduced body weight was observed in test group 4 (-13% in comparison to the control). However, the ecological significance of such a deviation is considered to be low and may be easily caused by very slight deviations in the environmental conditions. E.g. the lowest mean body weight in the replicates of the control group (replicate 0B) is 16% lower than the highest mean body weight measured in replicate 0A. Therefore the observed decrease in body weight is not necessarily substance-related. The results are summarized in Table 8.2.2.1-1.

Table 8.2.2.1-1: Chronic toxicity of alpha-cypermethrin to fathead minnow (*P. promelas*) in an fish early life stage test (34 d)

Peak concentration [µg/L] (nominal)	**Control**	**0.15**	**0.30**	**0.15**	**0.30**
Embryo survival until hatch [%]	94	94	94	96	97
Survival of larvae from hatch until end of swim-up (day 8) [%]	97	98	97	97	92

[1)] Calculated on the basis of the individual values.

III. CONCLUSION

In an early life stage study applying a realistic pulse dose exposure pattern with two peaks of alpha-cypermethrin, no substance-related effects on fathead minnow (*Pimephales promelas*) were observed at a nominal peak exposure concentration of 0.30 µg a.s./L.

CA 8.2.2.2 Fish full life cycle test

The chronic toxicity to fish is fully addressed in two early life stage studies (one of these studies was already evaluated during the previous Annex I inclusion process; the second study was performed for risk refinement in support of EU product registrations). No additional fish full life cycle study is required and no (new) study has been conducted.

CA 8.2.2.3 Bioconcentration in fish

Two bioconcentration studies performed with *cypermethrin* were evaluated during the Annex I inclusion process of alpha-cypermethrin. However, a specific alpha-cypermethrin study was missing, which is now included. In the framework of this BCF study, an acute toxicity study was conducted using Japanese medaka (*Oryzias latipes*) which has not been evaluated previously on EU level. Thus, a summary of the bioconcentration study is provided, which also includes data and results of the acute toxicity testing.

Report: CA 8.2.2.3/1
[redacted] 1997a
Bioconcentration study of Alpha-Cypermethrin with carp
AL-519-004
Guidelines: OECD 305
GLP: yes

Executive Summary

The bioconcentration potential of alpha-cypermethrin (BAS 310 I) was investigated in common carp (*Cyprinus carpio*) in a flow-through system. Animals were exposed to the test item at a low and a high exposure level of 0.010 and 0.10 µg a.s./L, respectively, for a 73-day uptake phase. Additionally, a dilution water control was set up. Subsequently, fish were kept in dilution water for 2 weeks (depuration phase). Fish samples for determination of test item concentrations in fish were taken on weeks 2, 4, 6, 8 and 10 after start of exposure. Analysis of the test item in tissues and organs of the test fish was carried out on day 73 after test initiation. From the results of the elimination test, half-lives of the test item in fish body were determined.
In addition, a 48-hour static acute toxicity laboratory study was conducted in parallel. In this study medaka (*Oryzias latipes*) were exposed to a solvent control (acetonitrile and dispersing agent HCO-30) and to nominal concentrations of 2.0, 3.6, 6.5, 12 and 20 µg alpha-cypermethrin/L (nominal) in groups of 10 animals. Fish were observed for survival 24 and 48 hours after start of exposure.

Bioconcentration test: No toxic effects like increased mortality or changes in behavior or appearance were observed in the test item treatment organisms. The bioconcentration factors (BCFs) of the test item at both exposure levels appeared to reach steady-state plateau by week 4 of exposure. The maximum BCF values at high and low exposure levels were 579 and 910, respectively. The elimination test revealed that half-life of the test item in fish was 8.6 days at the high exposure level and 6.9 days at the low exposure level. From the result of the tissue distribution analysis, the BCFs of the test substance in tissue (of fish exposed for 10 weeks) were the highest in viscera and lowest in fillet.

Acute toxicity test: The biological results are based on nominal concentrations. After 48 hours of exposure, no mortality was observed in the solvent control and at test item concentrations of up to and including 6.5 µg a.s./L, whereas 50% mortality was observed at 12 µg a.s./L and 100% mortality occurred at the highest tested concentration of 20 µg a.s./L. The LC_{50} (48 h) of alpha-cypermethrin was determined to be 12.0 µg a.s./L.

In a flow-through bioconcentration study, common carp were exposed to ^{14}C-labeled alpha-cypermethrin at nominal concentrations of 0.010 and 0.10 µg a.s./L in water. The maximum BCF values obtained in this study during the uptake period were 910 and 579 for the nominal test item concentrations of 0.010 and 0.10 µg a.s./L, respectively. In the static acute toxicity study with medaka (*Oryzias latipes*), the LC_{50} (48 h) of alpha-cypermethrin was 12 µg a.s./L, based on nominal concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Non-radiolabelled alpha-cypermethrin (BAS 310 I, Reg. No. 4 078 193; batch no. AC10194-61, purity 96.1%); ^{14}C-labeled BAS 310 I (alpha-cypermethrin; batch-no.: AC10727-40A), specific activity: 60.8 µCi/mg, chemical purity: > 99%, radiochemical purity: 99.6%.

B. STUDY DESIGN

Test species: Bioconcentration test: Common carp (*Cyprinus carpio*), body weight: 22 - 46 g; body length: 9 - 13 cm, mean fat content: 5.0%; source: Sankyo Suisan Co, Tokyo, Japan.
Acute toxicity test: medaka (*Oryzias latipes*); body length: approx. 2 cm; body weight: approx. 0.2 g; supplied by Niikura Fishing (1217 Shimotani, Isehara, Kanagawa, Japan).

Test design: Bioconcentration test: flow-through system (73 days uptake, 2 weeks depuration); two test item treatments plus a dilution water control treatment, one test vessel per treatment with 12 fish per vessel for the control and 22 fish per vessel for the test item treatments at the start of the uptake period. Stock solutions were prepared with acetonitrile and dispersing agent HCO-30. For the depuration phase the test water in the aquaria was replaced by dilution water.
Analysis of the test item concentration in test water was conducted twice a week during the uptake period of 73 days. Fish samples for determination of test item concentrations in fish were taken on weeks 2, 4, 6, 8 and 10 after start of exposure.

	Analysis of the test item in tissues and organs of the test fish was carried out on day 73 after test initiation. After 73 days of exposure, an elimination test was carried out for 2 weeks for each exposure level. Two fish were collected from both exposure aquaria on days 4, 7 and 14 after the initiation of the elimination test. From the results of the elimination test, half-lives of the test item in fish body were determined. Acute toxicity test: Static system (48 h); 5 test item concentrations plus a control; 10 fish per aquarium; stock solutions were prepared with acetonitrile and dispersing agent HCO-30; assessment of mortality 24 hours and 96 hours after start of exposure.
Endpoints:	Bioconcentration test: bioconcentration potential (bioconcentration factor, BCF), depuration half-life. Acute toxicity test: LC_{50}, mortality.
Test concentrations:	Bioconcentration test: Water control, 0.010, 0.10 µg a.s./L (nominal). Acute toxicity test: Solvent control (0.2 µg HCO-30/L and 0.002 mL acetonitrile/L), 2.0, 3.6, 6.5, 12 and 20 µg alpha-cypermethrin/L (nominal).
Test conditions:	Bioconcentration test: 50 L glass aquaria (60 x 30 x 36 cm); water volume: approx. 45 L; flow-through system; dilution water: deionized water; temperature: 25 °C ± 2 °C; oxygen content: > 4 mg/L; turnover rate for each aquarium: 9 times/day, flow rate: 400 L/day/aquarium; population density: exposure groups: 22 fish / 45 L test water, control group: 12 fish / 45 L test water; continuous aeration, feeding: commercial fish diet (Minipet) at approx. 2.5% of the body weight once per day. Acute toxicity test: Test volume: 3 L; dilution water: dechlorinated water; temperature: 25 ± 2°C; oxygen content: > 5.4 mg/L; continuous aeration; no feeding.
Analytics:	Bioconcentration test: Determination of test item concentrations in water and fish or tissue samples was conducted by radioactivity measurements using Liquid Scintillation Counting (LSC). Acute toxicity test: not reported.
Statistics:	Bioconcentration test: calculations according to OECD test guideline 305. Acute toxicity test: Descriptive statistics; graphical determination of LC_{50}.

II. RESULTS AND DISCUSSION

Analytical results

Test item concentration in the water: For the bioconcentration test, analysis of the test item concentration in test water was conducted twice a week during the uptake period of 73 days. The average concentration of the test substance in water during the uptake period was 0.110 ± 0.0173 µg a.s./L for the high exposure level and 0.0113 ± 0.00321 µg a.s./L for the low exposure level. For the acute toxicity test, analytical verification of test item concentrations was not conducted and the following biological results are based on nominal concentrations.

*Test item concentrations in fish: T*he maximum concentrations of the test item in fish during the uptake period were 66.0 ng a.s./g and 9.65 ng a.s./g at the high and the low exposure level, respectively.

Biological results

Bioconcentration test: No toxic effects like increased mortality or changes in behavior or appearance were observed in the test item treatment organisms. The BCFs of the test item at both exposure levels appeared to reach steady-state plateau by week 4 of exposure. The maximum BCF values at high and low exposure levels were 579 and 910, respectively. The elimination test carried out after 10 weeks of exposure revealed that half-life of the test item in fish was 8.6 days at the high exposure level and 6.9 days at the low exposure level. From the result of the tissue distribution analysis, the BCF of the test substance in tissue (of fish exposed for 10 weeks) was the highest in viscera and lowest in fillet. The results are summarized in Table 8.2.2.3-1.

Table 8.2.2.3-1: Bioconcentration Factors (BCF) obtained during the uptake period

Exposure period (weeks)			**2**	**4**	**6**	**8**	**10**
High exposure level	Mean test item concentration in test water [µg a.s./L]		0.109	0.110	0.114	0.114	0.112
	BCF	Sample fish No. 1	286	466	406	458	388
		Sample fish No. 2	294	294	426	579	303

	BCF	Sample fish No. 1	155	567	903	441	463
		Sample fish No. 2	138	474	910	422	304

Acute toxicity test: After 48 hours of exposure, no mortality was observed in the solvent control and at test item concentrations of up to and including 6.5 µg a.s./L, whereas 50% mortality was observed at 12 µg a.s./L and 100% mortality occurred at the highest tested concentration of 20 µg a.s./L. **The LC_{50} (48 h) of alpha-cypermethrin was determined to be 12.0 µg/L.** The results are summarized in Table 8.2.2.3-2.

Table 8.2.2.3-2: Acute toxicity (48 h) of alpha-cypermethrin on medaka (*Oryzias latipes*)

Concentration [µg/L] (nominal)	**Control**	**2.0**	**3.6**	**6.5**	**12**	**10**
Mortality (48 h) [%]	0	0	0	0	50	100
Endpoint [µg/L] (nominal)						
LC_{50} (48 h)	12					

III. CONCLUSION

In a flow-through bioconcentration study, common carp were exposed to ^{14}C-labeled alpha-cypermethrin at nominal concentrations of 0.010 and 0.10 µg a.s./L in water. The maximum BCF values obtained in this study during the uptake period were 910 and 579 for the nominal test item concentrations of 0.010 and 0.10 µg a.s./L, respectively.
In the static acute toxicity study with medaka (*Oryzias latipes*) the LC_{50} (48 h) of alpha-cypermethrin was 12 µg a.s./L based on nominal concentrations.

CA 8.2.3 Endocrine disrupting properties

Based on the physical, chemical and structural characteristics of the active substance alpha-cypermethrin as well as based on results of available long-term fish studies (and studies on terrestrial vertebrates; see chapter MCA-8.1.5) there is no indication of endocrine disrupting properties of this active substance. Thus, no further studies are required.

CA 8.2.4 Acute toxicity to aquatic invertebrates

CA 8.2.4.1 Acute toxicity to Daphnia magna

To study the influence of organic matter on the bioavailability and toxicity of alpha-cypermethrin to the standard sensitive arthropod species *Daphnia magna*, an acute higher tier study was conducted in the presence of humic acid and green algae (thus incorporating a contaminated food route). In parallel, a treatment series without organic material (i.e. a standard test) was run.
The study was already listed in the "Application" document submitted for the alpha-cypermethrin AIR 3 renewal process. Two previous runs of the study were invalid due to stability issues with the used test item batch as confirmed by analytical values. In 2015 a 3rd, valid, run of the study was started and is reported here.

New non-standard study conducted on the representative alpha-cypermethrin solo-formulation BAS 310 55 I. Study was submitted under the AIR3 process.

Report:	CA 8.2.4.1/1 Weltje L., Janson G.-M., 2015a The influence of humic acid and green algae on the toxicity of BAS 310 55 I to Daphnia magna STRAUS 2013/1404157
Guidelines:	OECD 202, EPA 850.1010 draft April 1996
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute test, water flea neonates were exposed to BAS 310 55 I at nominal concentrations of 0.6, 2, 6 and 20 µg BAS 310 55 I/L (for the mean measured concentrations in the different test setups see below) in 4 replicates per concentration, each containing 5 daphnids. A dilution water control was tested in parallel. Three setups were run: dilution water only (M4-medium), M4-water with humic acid, and M4-water with green algae. The test item was dispersed in M4-water and diluted with the respective test water (M4-water, M4-water with humic acid, resp. M4-water with green algae) to obtain the desired test concentrations. Daphnids were observed for immobility 24 hours and 48 hours after start of exposure.

The biological results are based on mean measured concentrations of the test item. After 48 hours no immobility of daphnids exposed to BAS 310 55 I in M4-water only was observed in the control and at the lowest test item concentration of 0.40 µg/L, whereas the three highest BAS 310 55 I concentrations in M4-water showed statistically significantly reduced mobility of daphnids of 25%, 45% and 80%, respectively. Regarding the effects of BAS 310 55 I in M4-water with humic acid, no statistically significant effect on mobility was observed in the control treatment and at test

item concentrations of 0.5, 1.6 and 4.0 µg/L, whereas the highest treatment concentration of 13 µg/L showed a statistically significant reduction of mobility by 55%. Mobility of daphnids exposed to BAS 310 55 I in M4-water with green algae was not affected in the control and at the two lowest test item concentrations of 0.42 and 1.2 µg/L, while at 3.6 µg/L 5% immobility was observed. The highest treatment of 14 µg/L showed a statistically significant inhibition of 50%.

In a 48-hour static acute toxicity test with *Daphnia magna* exposed to BAS 310 55 I the lowest EC_{50} was obtained in the standard setup with M4-water and was 3.6 µg/L based on mean measured concentrations. The corresponding NOEC was 0.4 µg/L. In the test water with humic acid and green algae, the EC_{50} values were determined to be 10.3 and 13.9 µg/L, respectively. The corresponding NOEC values were 4.0 and 3.6 µg/L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 310 55 I, batch no. FD-150123-0010, content of a.s.: alpha-cypermethrin (BAS 310 I, Reg. No. 4 078 193): 49.9 g analyzed (50.0 g/L nominal).

B. STUDY DESIGN

Test species: Water flea (*Daphnia magna* STRAUS), neonates from in-house culture (originally obtained from Institute National de Recherché Chimique Appliquée, France), > 2 < 24 hours old at test initiation.

Test design: Static system (48 hours), 3 parallel test setups were run: M4-water only, M4-water with humic acid and M4-water with green algae; each setup with 4 test concentrations plus a control, 4 replicates per concentration with 5 daphnids in each; assessment of immobility after 24 and 48 hours.

Endpoints: EC_{50} and NOEC based on immobility of daphnids.

Test concentrations: M4-water, M4-water with humic acid or M4-water with green algae with 0 (control), 0.6, 2, 6 and 20 µg BAS 310 55 I/L (nominal), corresponding to the following mean measured concentrations: M4-water: 0.40, 1.1, 2.9, 12.5 µg/L; M-4 water with humic acid: 0.50, 1.6, 4.0, 13 µg/L; M-4 water with algae: 0.42, 1.2, 3.6, 14 µg/L.

Test conditions: Glass vessels, test volume 50 mL, dilution water: "M4" (Elendt medium); M4-water with humic acid: humic acid sodium salt was added to obtain a total organic carbon (TOC) of 6.4 mg/L (25.6 mg humic acid/4000 mL M4-water); M4-water with green algae: M4-water was inoculated with *Desmodesmus subspicatus* to obtain a TOC of 4 mg/L (10.06 mL green algae/4000 mL M4-water); temperature: 20.8°C - 21.3°C; pH 7.90 - 8.28; oxygen content: 8.47 mg/L – 9.13 mg/L; total hardness: 2.51 mmol/L; conductivity: 670 µS/cm; photoperiod: 16 hours light : 8 hours dark; light intensity: 208 - 560 lux; no feeding and no aeration.

Analytics: Analytical verification of test item concentrations was conducted using a GC-method with MS-detection.

Statistics: Descriptive statistics; EC_{50} was calculated using probit analysis, Fisher's Exact Binomial Test with Bonferroni Correction for determination of the NOEC.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in the controls and the test item treatments at the beginning and at the end of the test. Measured values for BAS 310 55 I (M4-water) were 44 - 84% of nominal concentrations at test initiation and 51 - 61% of nominal at test termination. Measured values for BAS 310 55 I (M4-water with humic acid) were 57 - 93% of nominal at test initiation and 73 - 80% of nominal at test termination. Measured values for BAS 310 55 I (M4-water with green algae) were 82 - 94% of nominal at test initiation and 31 - 62% of nominal at test termination. Biological results were based on mean measured concentrations.

Biological results: After 48 hours no immobility of daphnids exposed to BAS 310 55 I in standard M4-water was observed in the control and at the lowest test item concentration of 0.40 µg/L, whereas the three highest BAS 310 55 I concentrations in M4-water showed statistically significantly reduced mobility of daphnids of 25%, 45% and 80% (Fisher's Exact Binominal Test with Bonferroni Correction, $p < 0.05$), respectively. Regarding the effects of BAS 310 55 I in M4-water with humic acid, no statistically significant effect on mobility was observed in the control treatment and at test item concentrations of 0.5, 1.6 and 4.0 µg/L, whereas the highest treatment concentration of 13 µg/L showed a statistically significant reduction of mobility by 55% (Fisher's Exact Binominal Test with Bonferroni Correction, $p < 0.05$). Mobility of daphnids exposed to BAS 310 55 I in M4-water with green algae was not significantly affected in the control and at the three lowest test item concentrations, whereas the highest treatment of 14 µg/L showed statistically significant inhibition of 50% (Fisher's Exact Binominal Test with Bonferroni Correction, $p < 0.05$). For results see Table 82.4.1-1.

Table 8.2.4.1-1: Effect of BAS 310 55 I on *Daphnia magna* mobility

Setup	**Concentration [µg/L] (nominal)**	**Control**	**0.6**	**2**	**6**	**20**

	Endpoints [µg BAS 310 55 I/L] (mean measured)					
	EC_{50} (48 h)	13.9 (95% confidence limits: 9.5 – 30.6)				
	NOEC (48 h)	3.6				

* Statistically significantly different compared to the control (Fisher's Exact Binominal Test with Bonferroni Correction, $p < 0.05$)

III. CONCLUSION

In a 48-hour static acute toxicity test with *Daphnia magna* exposed to BAS 310 55 I the lowest EC_{50} was obtained in the standard setup with M4-water and was 3.6 µg/L based on mean measured concentrations. The corresponding NOEC was 0.4 µg/L. In the test water with humic acid and green algae, the EC_{50} values were determined to be 10.3 and 13.9 µg/L, respectively. The corresponding NOEC values were 4.0 and 3.6 µg/L.

Study Comments: 8.2.4.1/1	
Agreed Endpoint: 8.2.4.1/1	

CA 8.2.4.2 Acute toxicity to an additional aquatic invertebrate species

The following acute toxicity study with the active substance alpha-cypermethrin on larvae and pupae of the phantom midge *Chaoborus crystallinus* is provided for aquatic risk refinement and has not been evaluated previously. This study has erroneously been listed under 10.2.4.1 in the application submitted for renewal of approval.

Report: CA 8.2.4.2/1
Janson G.-M.,Weltje L., 2009b
Acute toxicity of BAS 310 I (Reg.No. 4078193) to larvae of the phantom midge Chaoborus crystallinus in a 48 hour static test
2009/1085205
Guidelines: OECD 202
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a static acute toxicity laboratory study, larvae of the phantom midge *Chaoborus crystallinus* (Diptera, Chaoboridae) were exposed to alpha-cypermethrin (BAS 310 I) at nominal concentrations of 0 (control), 0 (solvent control), 6.25, 12.5, 25, 50 and 100 ng/L in 4 replicates per concentration, containing 5 larvae each. Additionally, a solvent control and a 50 ng/L treatment were initiated with four replicates, containing 5 pupae in each. Midge larvae and pupae were observed for immobility and other signs of toxicity 24 hours and 48 hours after start of exposure.

The biological results are based on geometric mean measured concentrations. After 24 and 48 hours of exposure statistically significant effects on larval mobility compared to the pooled control were observed at the two highest test item concentrations of 42.43 and 92.47 ng a.s./L. In the two lowest treatments and in the controls some larvae pupated (a sign for normal development). Since the pupae are mobile as well, mobility assessments were made in the same way as for larvae. At test end (48 h) 30% immobility of pupae was observed at a test item concentration of 42.43 ng a.s./L compared to 55% immobility of larvae. Thus, it was shown that pupae of *C. crystallinus* are less sensitive to alpha-cypermethrin than larvae.

In a 48-hour static acute toxicity study with *Chaoborus crystallinus* larvae the EC_{50} of alpha-cypermethrin was 44.54 ng a.s./L based on geometric mean measured concentrations. The NOEC was determined to be 24.87 ng a.s./L (geometric mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg. No. 4078193), batch no. COD-000595, purity: 99.7% (tolerance ± 1%).

B. STUDY DESIGN

Test species: *Chaoborus crystallinus* (phantom midge, Diptera, Chaoboridae); maintained in-house (non-GLP) for an acclimation period of at least 5 days (obtained from pet shop "Koelle Zoo", Ludwigshafen, Germany), body length of approx. 1.1 - 1.2 cm at test initiation.

Test design: Static system (48 hours), 5 test concentrations plus water and solvent control, 4 replicates with 5 larvae in each; additionally a solvent control and one test concentration (50 ng a.s./L) with 4 replicates, each containing 5 pupae; assessment of immobility after 24 and 48 hours.

Endpoints: NOEC, EC_{50} based on immobility.

Test concentrations: 0 (control), 0 (solvent control), 6.25, 12.5, 25, 50 and 100 ng a.s./L (nominal); corresponding to geometric mean measured concentrations of 8.31, 12.47, 24.87, 42.43 and 92.47 ng a.s./L.

Test conditions: 250 mL glass vessels, test volume 150 mL, filtered natural water from mesocosm pond; pH 7.94 - 8.14; oxygen content: 8.4 - 9.1 mg/L; total hardness: 2.23 mmol/L at test initiation; conductivity: 552 µS/cm at test initiation; temperature: 20.3 - 20.6 °C; light intensity 620 - 936 lux; photoperiod: 16 h light : 8 h dark, no feeding, no aeration.

Analytics: Analytical verification of test item concentrations was conducted using a GC/ECD method.

Statistics: Descriptive statistics; Fisher's exact test ($p < 0.05$) for determination of the NOEC; probit analysis for determination of the EC_{50} value.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentration was conducted in each concentration at the beginning and at the end of the test. Measured concentrations for alpha-cypermethrin ranged from 90% to 147% of nominal at test initiation and from 80% to 120% of nominal at test termination. The following biological results are based on geometric mean measured concentrations.

Biological results: Since there were no statistical differences between the control and the solvent control (t-test, $p < 0.05$) controls were pooled for comparison with the treatments. After 24 and 48 hours of exposure statistically significant effects on larval mobility compared to the pooled control were observed at the two highest test item concentrations of 42.43 and 92.47 ng a.s./L (Fisher's exact test, $p < 0.05$). In the two lowest treatments and in the controls some larvae pupated (a sign for normal development). Since the pupae are mobile as well, mobility assessment was made in the same way as for larvae. At test end (48 h) 30% immobility of pupae was observed at a test item concentration of 42.43 ng a.s./L compared to 55% immobility of larvae. Thus, it was shown that pupae of *C. crystallinus* are less sensitive to alpha-cypermethrin than larvae. For results see Table 8.2.4.2-1.

Table 8.2.4.2-1: Effects of alpha-cypermethrin on the mobility of *Chaoborus crystallinus*

Concentration [ng a.s./L] (geom. mean measured)	**Control**	**Solvent control**		**8.31**	**12.47**	**24.87**	**42.43**		**92.47**

NOEC (48 h)	24.87								

* Statistically significant different compared to the pooled control (Fisher's exact test, $p < 0.05$).
\# Immobility of pupae

III. CONCLUSION

In a 48-hour static acute toxicity study with *Chaoborus crystallinus* larvae the EC_{50} of alpha-cypermethrin was 44.54 ng a.s./L based on geometric mean measured concentrations. The NOEC was determined to be 24.87 ng a.s./L (geometric mean measured).

CA 8.2.5 Long-term and chronic toxicity to aquatic invertebrates

CA 8.2.5.1 Reproductive and development toxicity to Daphnia magna

The following chronic pulse-dose study toxicity study on *Daphnia magna* performed with the active substance alpha-cypermethrin is provided in support of the aquatic risk assessment and has not been evaluated previously on EU level.

Report:	CA 8.2.5.1/1 Bergtold M., 2007a Chronic toxicity of BAS 310 I to Daphnia magna STRAUS in a 21 day semi-static test - A time to effect study 2007/1016502
Guidelines:	OECD 211, EPA 850.1300
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a semi-static chronic toxicity laboratory study, water flea neonates (between 2 and 24 hours old) were exposed to alpha-cypermethrin (BAS 310 I) at peak concentrations of 0.0372, 0.0744, 0.1117 and 0.1489 µg a.s./L. To evaluate chronic effects after a realistic exposure scenario, a semi-static test has been conducted simulating peak concentrations after two applications of the test item (7 days interval) with subsequent dissipation. Daphnids were observed for parent mortality; body length and reproductive performance throughout the test period.

No mortality of the parent daphnids was observed in the controls and in the treatment with 0.0372 µg a.s./L peak concentration. One daphnid died at concentrations of 0.0744 µg a.s./L and 0.1117 µg a.s./L peak concentration and three daphnids died at 0.1489 µg a.s./L peak concentration. There was no significant treatment effect on mortality. First brood was observed on day 8-12 in the controls and on day 9-13 in the treatments. The number of offspring varied between 112.9 and 127.1. No significant effects on reproduction were found in the treatments compared to the pooled controls. Mean body length of the daphnids varied between 4.26 mm to 4.44 mm. Statistical analysis showed a minor effect on body length in the treatment with 0.1489 µg a.s./L peak concentrations compared to the pooled controls. The effect was judged to be ecologically not relevant.

In a 21-day semi-static chronic toxicity study with *Daphnia magna* no significant effects of the test item were observed on reproduction at the highest treatment comprising two peaks of 0.149 µg a.s./L alpha-cypermethrin (BAS 310 I), whereas a minimal (i.e. 3.2%) effect on body length occurred. As this was judged to be of no ecological relevance, the overall NOAEC is 0.149 µg a.s./L.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg.No. 4078193), batch no. COD-000595, purity: 99.7%.

B. STUDY DESIGN

Test species: Water flea (*Daphnia magna* STRAUS), neonates at test initiation between 2 and 24 hours old; from in-house culture.

Test design: Semi-static test (21 days) with renewal of test water on day 3, 5, 7, 10, 12, 14, 17 and 19; 6 treatment groups (4 test item concentrations, control, solvent control); 10 replicates with 1 daphnid in each treatment; assessment of parent mortality and reproduction throughout the test period; body length at test end.

Endpoints: Parent mortality; body length and reproductive performance.

Test concentrations: Control, solvent control, 0.0372, 0.0744, 0.1117 and 0.1489 µg a.s./L (peak concentrations).

Test conditions: M4 Elendt medium, 50 mL test volume; pH 7.92 - 8.15 (new test solutions), pH 7.74 - 8.13 (old test solutions); oxygen content: 8.38 mg/L - 9.43 mg/L (new test solutions), 7.92 mg/L - 9.43 mg/L (old test solutions); total hardness: 2.30 mmol/L - 2.60 mmol/L (old test solutions); light intensity: approx. 120 lux - 450 lux; temperature 18.9 °C - 21.1 °C (new test solutions), 19.4 °C - 21.0 °C (old test solutions); photoperiod: 16 h light : 8 h dark; feeding with algae, no aeration.

Analytics: The test item concentrations were analyzed using GC with MS-detection.

Statistics: Descriptive statistics, ANOVA followed by Bonferroni-test and William's-test for body length and reproduction data; Fisher's exact test for mortality ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of the test item was performed in all peak concentrations at study start (day 0) and day 7 in the new test water. Recovery of the test item was in the range of 71.2% to 133.9% and 78.7% to 118.7% of the nominal concentration at day 0 and at day 7, respectively. At the other days of test water exchange the concentration was determined in the stock solutions, where the recovery was in the range of 79.6 and 111.8% of the nominal values.

Biological results: No mortality of the parent daphnids was observed in the controls and in the treatment with 0.0372 µg a.s./L peak concentration. One daphnid died at concentrations of 0.0744 µg a.s./L and 0.1117 µg a.s./L peak concentration and three daphnids died at 0.1489 µg a.s./L peak concentration. There was no significant treatment effect on survival (Fisher's exact test, $\alpha = 0.05$). First brood was observed on day 8-12 in the controls and on day 8-13 in the treatments. The number of offspring varied between 112.9 and 127.1. No significant effects on reproduction were found in the treatments compared to the pooled controls (Bonferroni-test, William's-test, $\alpha = 0.05$, replicates with dead parent daphnids were excluded from statistical evaluation). Mean body length of the daphnids varied between 4.26 to 4.44 mm. Statistical analysis showed a minor but significant effect in the treatment with 0.1489 µg a.s./L peak concentration compared to the pooled controls (Bonferroni test, Williams' test, $\alpha = 0.05$). Although significant, body length was reduced by only 3.2% and thus not considered to be of biological relevance. The results are summarized in Table 8.2.5.1-1.

Table 8.2.5.1-1: Effect (21 d) of alpha-cypermethrin (BAS 310 I) on *Daphnia magna*

Concentration [µg a.s./L] [1)]	**Control**	**Solvent control**	**0.0372**	**0.0744**	**0.1117**	**0.1489**

Mean body length [mm]	4.43	4.37	4.44	4.31	4.73	4.26*

1) Peak concentration

* significant difference compared to the pooled controls (Bonferroni's, Williams' test, $\alpha = 0.05$). Body length was reduced by 3.2%.

III. CONCLUSION

In a 21-day semi-static chronic toxicity study with *Daphnia magna* no significant effects of the test item were observed on reproduction at the highest treatment comprising two peaks of 0.149 µg a.s./L alpha-cypermethrin (BAS 310 I), whereas a minimal (i.e. 3.2%) effect on body length occurred. As this was judged to be of no ecological relevance, the overall NOAEC is 0.149 µg a.s./L.

CA 8.2.5.2 Reproductive and development toxicity to an additional aquatic invertebrate species

No study required; thus, this point is not addressed *via* (new) toxicity studies.

CA 8.2.5.3 Development and emergence in Chironomus riparius

The following acute water-only toxicity study on *Chironomus riparius* larvae with the active substance alpha-cypermethrin was conducted to fulfill the data requirements for Annex I renewal and has not been evaluated previously.

Report:	CA 8.2.5.3/1 Janson G.-M. et al., 2011a Acute toxicity of Alpha-Cypermethrin (BAS 310 I) and of Cypermethrin (BAS 311 I) to the non-biting midge Chironomus riparius in a 48 hour static test 2009/1102214
Guidelines:	OECD 202
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 48 hours static acute toxicity study, non-biting midge larvae (*Chironomus riparius*) were exposed to alpha-cypermethrin at nominal test concentrations of 0 (control), 5, 10, 20, 40 and 80 ng a.s./L in 4 replicates per concentration, containing 5 larvae each. Chironomids were observed for immobility 24 hours and 48 hours after start of exposure.

The biological results are based on mean measured concentrations of alpha-cypermethrin. After 24 h no significant effects on mobility of chironomids was observed up to and including a concentration of 40 ng a.s./L. After 48 h no significant effects on mobility of chironomids was observed at test item concentrations of 5 and 10 ng a.s./L. Sublethal effects, like lethargy of mobile larvae, were observed in the three highest test concentrations after 24 h and after 48 h in almost all tested concentrations.

In a 48 h static acute toxicity study with *Chironomus riparius* the EC_{50} of alpha-cypermethrin was determined to be 12.6 ng a.s./L based on mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg. No. 4078193), batch no. COD-000595, purity: 99.2%.

B. STUDY DESIGN

Test species: Non-biting midge (*Chironomus riparius*), first instar larvae; source: in-house culture.

Test design: Static system (48 hours), 5 test concentrations plus control, 4 replicates per concentration and control; 5 larvae per replicate; assessment of immobility after 24 h and 48 h .

Endpoints: NOEC and EC_{50} (regarding immobilization).

Test concentrations: Control, 5, 10, 20, 40 and 80 ng alpha-cypermethrin/L (nominal).

Test conditions: Glass vessels, 50 mL M4 water (Elendt medium); pH 7.93 - 8.04; oxygen content: 8.4 - 9.2 mg/L; total hardness: 2.45 mmol/L (at test initiation); conductivity: 665 µS/cm (at test initiation); water temperature: 20.9 - 21.0°C; light intensity: 600 lux; photoperiod: 16 h light : 8 h dark; no feeding, no aeration.

Analytics: The test item concentrations were analyzed using a GC-ECD method after liquid-liquid extraction of the test item into hexane.

Statistics: Descriptive statistics, Fisher´s exact test ($\alpha = 0.05$) for determination of NOEC; probit analysis for determination of EC_{50}.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each concentration at the beginning and the end of the test. Recoveries for alpha-cypermethrin (Reg. No. 4078193) were in a range of 58% - 80% (average 65.6%) of the nominal concentrations at test initiation and 40% - 80% (average 63.6%) at test termination. The following mean measured concentrations were derived: 4, 6.5, 14, 23.5 and 39 ng a.s./L. The biological results are based on mean measured concentrations of alpha-cypermethrin.

Biological results: BAS 310 I: After 24 h no significant effects on mobility of chironomids was observed up to and including a concentration of 40 ng alpha-cypermethrin /L. After 48 h no significant effects on mobility of chironomids was observed at test item concentrations of 5 and 10 ng a.s./L. Sublethal effects were observed after 24 h in the concentrations 20, 40 and 80 ng a.s./L, and after 48 h, in the test item concentrations 5, 10, 20 and 40 ng a.s./L; the mobile larvae appeared lethargic. The results are summarized in Table 8.2.5.3-1.

Table 8.2.5.3-1: Effects of alpha-cypermethrin on *Chironomus riparius* immobility

Concentration (nominal) [ng a.s./L]	**Control**	**5**	**10**	**20**	**40**	**80**
Concentration (mean measured) [ng a.s./L]	**Control**	**4**	**6.5**	**14**	**23.5**	**39**

NOEC	6.5					

* Statistically significantly different from control (Fisher's Exact Test, $\alpha < 0.05$).

III. CONCLUSION

In a 48 h static acute toxicity study with *Chironomus riparius* larvae the EC_{50} of alpha-cypermethrin was determined to be 12.6 ng a.s./L based on mean measured concentrations.

An EU agreed spiked water study on *Chironomus riparius* performed with the active substance alpha-cypermethrin is already available. The following spiked sediment toxicity study was originally conducted for the biocide Annex I listing and is provided here in support of the aquatic risk assessment and has not been evaluated previously.

Report:	CA 8.2.5.3/2 Backfisch K.,Weltje L., 2011a Chronic toxicity of Reg.No. 4078193 (BAS 310 I; Alpha-Cypermethrin) to the non-biting midge Chironomus riparius - A spiked sediment study 2011/1124187
Guidelines:	OECD 218 (2004)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Report:	CA 8.2.5.3/3 Backfisch K.,Weltje L., 2012a Amendment No. 1 - Chronic toxicity of Reg.No. 4078193 (BAS 310 I; Alpha-Cypermethrin) to the non-biting midge Chironomus riparius - a spiked sediment study 2012/1156939
Guidelines:	OECD 218 (2004)
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 28-day static spiked sediment study, non-biting midge larvae (*Chironomus riparius*) were exposed to alpha-cypermethrin at nominal concentrations of 15, 30, 60, 120 and 240 µg a.s./kg dry sediment (corresponding to mean measured concentrations of 10.5, 22.5, 45.0, 84.5 and 148 µg a.s./kg dry sediment). Additionally, a solvent (acetone) control and a water control were set up. All test item concentrations and the water control had 4 replicates, whereas 6 replicates were tested for the solvent control. 20 larvae were added to each test vessel.

The biological results are based on mean measured concentrations of the test item. First emerged midges were observed on DAI 14 (= day after insertion of larvae). The solvent control data were used for statistical evaluation of treatment related effects. Statistically significant differences compared to the solvent control were found for the emergence rates at the two highest test item concentrations. Statistically significant effects on the development rate were observed in the three highest test item treatments.

In a 28-day static sediment test with *Chironomus riparius*, the EC_{10} values based on emergence rate and development rate were determined to be 51.4 µg a.s./kg dry sediment and 74.1 µg a.s./kg dry sediment, respectively (mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg. No. 4 078 193), batch no. COD-000595, purity: 99.2%.

B. STUDY DESIGN

Test species: Non-biting midge (*Chironomus riparius*), first instar larvae, not older than 2 days at test initiation; source: in-house culture (non-GLP), originally obtained from "Zoological Institute of the J.W. Goethe University", Frankfurt am Main, Germany.

Test design: Static system (28 days); 5 test concentrations plus a solvent (acetone) control and a water control, 4 replicates per test item concentration and for the water control, 6 replicates for the solvent control; 20 larvae were added to each test vessel; assessment of emergence rate and development rate.

Endpoints: NOEC, EC_{10} and EC_{50} (regarding emergence rate and development rate).

Test concentrations: Solvent (acetone) control, water control, 15, 30, 60, 120 and 240 µg a.s./kg dry sediment (nominal), corresponding to mean measured concentrations of 10.5, 22.5, 45.0, 84.5 and 148 µg a.s./kg dry sediment.

Test conditions: 600 mL glass vessels with 100 g spiked wet artificial sediment (according to OECD 218), 400 mL M4 water (Elendt medium) corresponding to a water layer of about 7.5 - 8.0 cm; pH 7.83 - 8.29; oxygen content: 7.89 - 10.06 mg/L; total hardness: 2.8 mmol/L; conductivity: 679 µS/cm; ammonia: 0.8 mg/L at test initiation and 2.0 mg/L at test termination; water temperature: 19.7 °C - 20.9 °C; light intensity: 536 - 952 lux; photoperiod: 16 h light : 8 h dark; continuous gentle aeration; food: TetraMin (0.25 - 1.0 mg food/larva/day until DAI 24.

Analytics: Analytical verification of test item concentrations in sediment was conducted using a GC-method with MS detection. Overlaying water concentrations were measured using a GC-method with ECD detection.

Statistics: Descriptive statistics, ANOVA followed by Williams' Multiple sequential t-test procedure for determination of the NOEC based on emergence and development rate ($\alpha = 0.05$); probit analysis using linear max. likelihood regression for determination of EC_x values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the overlying water, the pore water and the sediment was conducted in each concentration at the beginning and the end of the test. Recoveries in the sediment were in a range between 60.8% and 80.0% of the nominal concentrations at test initiation and 62.5% and 76.7% of nominal at test termination. Alpha-cypermethrin concentrations found in the overlaying water ranged from < 0.002 µg a.s./L (limit of quantification = 0.005 µg/L) to 0.049 µg a.s./L at test initiation and from < 0.002 to 0.036 µg a.s./L at test end. Measured pore water concentrations were between 0.031 and 0.210 µg a.s./L at the beginning of the test and between < 0.002 and 0.140 µg a.s./L at test termination. The following biological results are based on mean measured sediment concentrations.

Biological results: First emerged midges were observed on DAI 14. The solvent control data were used for statistical evaluation of treatment related effects. Statistically significant differences compared to the solvent control were found for the emergence rates at the two highest test item concentrations (Williams' Multiple sequential t-test procedure, $\alpha = 0.05$). Statistically significant effects on the development rate were observed in the three highest test item treatments (Williams' Multiple sequential t-test procedure, $\alpha = 0.05$). The results are summarized in Table 8.2.5.3-2.

Table 8.2.5.3-2: Effects of alpha-cypermethrin on emergence and development of *Chironomus riparius*

Concentration [µg a.s./kg dry sediment] (nominal)	**Control**	**Solvent control**	**15**	**30**	**60**	**120**	**240**
Concentration [µg a.s./kg dry sediment] (mean measured)	**--**	**--**	**10.5**	**22.5**	**45.0**	**84.5**	**148**
Emergence rate (ER) #	0.9125 ± 0.0479	0.9000 ± 0.0548	0.9000 ± 0.0408	0.8875 ± 0.1109	0.8125 ± 0.0479	0.7250 ± 0.1041 *	0.1250 ± 0.1190 *
Development rate per day (DR) #	0.0665 ± 0.0010	0.0672 ± 0.0016	0.0652 ± 0.0020	0.0651 ± 0.0033	0.0618 ± 0.0020 *	0.0594 ± 0.0013 *	0.0577 ± 0.0063 *
Endpoints [µg alpha-cypermethrin/kg dry sediment] (mean measured)							
$EC_{10\ emergence\ rate}$ (28 d)	51.4						
$EC_{10\ development\ rate}$ (28 d)	74.1						

Values represent mean and standard deviation from all replicates, each with 20 larvae.
* Statistically significant difference compared to the solvent control (Williams' Multiple sequential t-test procedure, $\alpha = 0.05$).

III. CONCLUSION

In a 28-day static sediment test with *Chironomus riparius*, the EC_{10} values based on emergence rate and development rate were determined to be 51.4 µg a.s./kg dry sediment and 74.1 µg a.s./kg dry sediment, respectively (mean measured).

CA 8.2.5.4 Sediment dwelling organisms

The following spiked sediment toxicity study on *Lumbriculus variegatus* conducted with the active substance alpha-cypermethrin was originally conducted for biocide Annex I listing and is provided here in support of the aquatic risk assessment and has not been evaluated previously.

Report:	CA 8.2.5.4/1 Gilberg D. et al., 2013a Alpha-Cypermethrin (BAS 310 I): A study on the chronic toxicity to the sediment dweller Lumbriculus variegatus 2012/1205915
Guidelines:	OECD 203 (1992), OECD 225 Sediment-water Lumbriculus toxicity test using spiked sediment (October 2007)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a 28-day static spiked sediment study, sediment-dwelling worms (*Lumbriculus variegatus*) were exposed to alpha-cypermethrin at nominal concentrations of 62.5, 125, 250, 500 and 1000 µg alpha-cypermethrin/kg dry sediment (corresponding to initial mean measured concentrations of 71.3, 143, 285, 570 and 1140 µg a.s./kg dry sediment). Additionally, a solvent (acetone) control was set up. All test item concentrations had 4 replicates, whereas 6 replicates were tested for the solvent control. 10 worms were added to each test vessel.

The biological results are based on initial mean measured concentrations of the test item. Concentration-dependent sediment avoidance, reduction, respectively, delay in production of fecal pellets and likely immobile worms on the sediment surface were observed at the three highest concentration levels. After 28 days of exposure, survival was not affected significantly up to and including the highest test item concentration. Since no meaningful number of dead worms (at test termination, only one worm was found to be dead, each in the test item treatments of 250 and 1000 µg a.s./kg dry sediment) and no concentration response relation was observed, no statistical evaluation was performed for the endpoint survival. Statistically significant differences compared to the solvent control were found for the parameters reproduction and total weight at the four highest test item concentrations, whereas for the parameter individual weight, statistically significant effects compared to the solvent control were observed at the three highest test item concentrations.

In a 28-day static sediment test with *Lumbriculus variegatus*, the NOEC values of alpha-cypermethrin were determined to be 71.3 µg a.s./kg dry sediment (initial mean measured) based on both reproduction and biomass and 143 µg a.s./kg dry sediment based on individual biomass (initial mean measured).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg. No. 4 078 193), batch no. COD-000595, purity: 99.4%.

B. STUDY DESIGN

Test species: Sediment-dwelling worm (*Lumbriculus variegatus*), synchronized adult worms of similar size; source: in-house culture, originally obtained from "Fischfutter Etzbach", Mechernich-Bergheim, Germany.

Test design: Static system (28 days); 5 test concentrations plus a solvent (acetone) control, 4 replicates per test item concentration, 6 replicates for the solvent control; 10 worms were added to each test vessel; assessment of reproduction (worm number), total weight and mean individual weight at test termination.

Endpoints: NOEC and EC_{50} (regarding reproduction, total weight and individual weight).

Test concentrations: Solvent (acetone) control, 62.5, 125, 250, 500 and 1000 µg alpha-cypermethrin/kg dry sediment (nominal), corresponding to initial mean measured concentrations of 71.3, 143, 285, 570 and 1140 µg a.s./kg dry sediment.

Test conditions: 250 mL glass vessels with 80 g spiked wet artificial sediment (according to OECD 225), reconstituted water (according to OECD 203), approximately 175 ml overlying water per test vessel; pH 7.6 - 8.1; oxygen content: 90% to 94%; total hardness: 273.3 - 292.9 mg $CaCO_3$/L; conductivity: 614 µS/cm; ammonia: < LOQ (limit of quantification = 1.3 mg/L) - 3.29 mg/L; water temperature: 20.3 °C - 20.7 °C; light intensity: 168 - 414 lux; photoperiod: 16 h light : 8 h dark; continuous gentle aeration; feed in sediment (addition of *Urtica*-powder (0.25% on dry sediment) and cellulose (0.25% on dry sediment) before application of the test item).

Analytics: Analytical verification of test item concentrations was conducted using a GC-MS-method.

Statistics: Descriptive statistics, Welch-t test and Williams t-test for determination of the NOEC values (α = 0.05), probit analysis for determination of EC_x values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the overlying water and the sediment was conducted in the test concentrations of 62.5 and 1000 µg a.s./kg dry sediment at the beginning and the end of the test. Recoveries in the sediment were in a range between 110% and 118% of the nominal concentrations at test initiation and 101% and 102% of nominal at test termination. Alpha-cypermethrin concentrations found in the overlaying water ranged from 4.0 to 63 ng a.s./L on day 0 and from 29 to 95 ng a.s./L of nominal on day 28. The following biological results are based on initial mean measured sediment concentrations.

Biological results: Concentration-dependent sediment avoidance, reduction, respectively delay in production of fecal pellets and likely immobile worms on the sediment surface were observed at the three highest concentration levels. After 28 days of exposure, survival was not affected significantly up to and including the highest test item concentration. Since no meaningful number of dead worms (at test termination, only one worm was found to be dead, each in the test item treatments of 250 and 1000 µg a.s./kg dry sediment) and no concentration response relation was observed, no statistical evaluation was performed for the endpoint survival. Statistically significant differences compared to the solvent control were found for the parameters reproduction and total weight at the four highest test item concentrations (Welch t-test, $\alpha = 0.05$), whereas for the parameter individual weight, statistically significant effects compared to the solvent control were observed at the three highest test item concentrations (Williams t-test, $\alpha = 0.05$). The results are summarized in Table 8.2.5.4-1.

\+ Statistically significant difference compared to the solvent control (Williams t-test, $\alpha = 0.05$).
a) Welch t-test could not be performed

III. CONCLUSION

In a 28-day static sediment test with *Lumbriculus variegatus*, the NOEC values of alpha-cypermethrin were determined to be 71.3 µg a.s./kg dry sediment (initial mean measured) based on both reproduction and biomass and 143 µg a.s./kg dry sediment based on individual biomass (initial mean measured).

The following chronic spiked sediment toxicity study on the nematode *Caenorhabditis elegans* conducted with the active substance alpha-cypermethrin was originally conducted for biocide Annex I listing and is provided here in support of the aquatic risk assessment and has not been evaluated previously.

Report:	CA 8.2.5.4/2 Hoess S., 2013a Chronic toxicity of Alpha-Cypermethrin to Caenorhabditis elegans exposed via spiked sediment according to ISO guideline 10872 (2010) 2013/1250848
Guidelines:	ISO 10872 (2010)
GLP:	yes (certified by Landesanstalt fuer Umwelt, Messungen und Naturschutz Baden-Wuerttemberg, Karlsruhe, Germany)

Executive Summary

In a chronic 96-h static spiked sediment study, nematodes (*Caenorhabditis elegans*) were exposed to alpha-cypermethrin. Nominal test concentrations were 300, 1000, 3000, 10000 and 30000 µg a.s./kg dry sediment (corresponding to mean measured concentrations of 230, 890, 3850, 7450 and 28650 µg a.s./kg dry sediment and to initial measured concentrations of 230, 730, 4390, 7510 and 28230 µg a.s./kg dry sediment). Additionally, a solvent (acetone) control and a dilution water control were set up. All test item concentrations, the dilution water control and the solvent control had 6 replicates. To each test vessel, 10 nematodes were added.

The biological results are based on mean measured concentrations, as well as on initial measured concentrations. Nematode growth and reproduction in the solvent control did not significantly differ from values of the control, meaning that no effect of the solvent occurred. The test item showed no significant inhibitory effect on growth and reproduction of *C. elegans* compared to the solvent control at any tested concentration. Even though the mean value was decreased in the lowest treatment group, the number of offspring did not differ significantly from the solvent control and was not considered to be a treatment related effect.

In a chronic 96-h static sediment test with *Caenorhabditis elegans* the NOEC of alpha-cypermethrin for both growth and reproduction was determined to be ≥ 28600 µg a.s./kg dry sediment (≥ 17200 µg a.s./kg wet sediment) based on mean measured concentrations and ≥ 28200 µg a.s./kg dry sediment (≥ 16900 µg a.s./kg wet sediment) based on initially measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg. no. 4 078 193), batch no. COD-000595, purity: 99.2% ± 1%.

B. STUDY DESIGN

Test species: Nematode (*Caenorhabditis elegans*), strain N2, wild type; first stage J1 at test beginning; initial body length: 275 ± 49 µm; source: Caenorhabditis Genetic Centre, Dept of GCD, University of Minnesota, Minneapolis, USA.

Test design: Static system (96 hours); 5 test concentrations plus a solvent (acetone) control and a dilution water control, 6 replicates per test item concentration and for the control groups; 10 test organisms per replicate; assessment of growth and reproduction.

Endpoints: NOEC based on growth and reproduction.

Test concentrations: Solvent (acetone) control, dilution water control, 300, 1000, 3000, 10000 and 30000 µg a.s./kg dry sediment (nominal), corresponding to mean measured concentrations of 230, 890, 3850, 7450 and 28650 µg a.s./kg dry sediment and to initial measured concentrations of 230, 730, 4390, 7510 and 28230 µg a.s./kg dry sediment.

Test conditions: 5 mL glass vessels with 0.5 g spiked wet artificial sediment (according to ISO 10872) and 0.2 mL M9 medium; food: bacterial suspension with 11,924 FAU; temperature: 19.5 °C - 20.0 °C.

Analytics: Analytical verification of test item concentrations was conducted using a GC-method with MS detection.

Statistics: Descriptive statistics, t-test for comparison of the control data ($p < 0.05$); one-way ANOVA followed by Dunnett's test ($p < 0.05$).

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations in the sediment was conducted in each concentration at the beginning and the end of the test. Recoveries in the sediment were in a range between 73% and 146 % of the nominal concentrations at test initiation. At test termination the detected concentrations ranged from 74% to 110% of the nominal values. The following biological results are based on mean measured sediment concentrations. Additionally, results are presented based on initial measured sediment concentrations.

Biological results: Nematode growth and reproduction in the solvent control did not significantly differ from values of the control (t-test, $p > 0.05$), meaning that no effect of the solvent occurred. The test item showed no significant inhibitory effect on growth and reproduction of *C. elegans* compared to the solvent control at any tested concentration (one-way ANOVA followed by Dunnett's test; $p > 0.05$). Even though the mean value was decreased in the lowest treatment group, the number of offspring did not differ significantly from the solvent control (one-way ANOVA followed by Dunnett's test; $p > 0.05$) and was not considered to be a treatment related effect. The results are summarized in Table 8.2.5.4-2.

Table 8.2.5.4-2: Effects of alpha-cypermethrin on growth and reproduction of *Caenorhabditis elegans* after 96 hours of exposure

Concentration [µg a.s./kg dry sediment] (nominal)	**300**	**1000**	**3000**	**10000**	**30000**
Concentration [µg a.s./kg dry sediment] (mean measured)	**230**	**890**	**3850**	**7450**	**28650**
Concentration [µg a.s./kg dry sediment] (initial measured)	**230**	**730**	**4390**	**7510**	**28230**
Growth (% Inhibition compared to solvent control) [#]	-1.6	-6.5	-2.9	-5.7	-2.3
Reproduction (Offspring / test organism) (% Inhibition compared to solvent control) [#]	30.5	-9.4	-5.9	-16.0	-24.4
	Endpoints [µg a.s./kg dry sediment] (mean measured / initially measured)				
$NOEC_{growth\ /\ reproduction}$	≥ 28600 / ≥ 28200				

[#] Negative inhibition values indicate higher performance than in the solvent control

III. CONCLUSION

In a chronic 96-h static sediment test with *Caenorhabditis elegans* the NOEC of alpha-cypermethrin for both growth and reproduction was determined to be ≥ 28600 µg a.s./kg dry sediment (≥ 17200 µg a.s./kg wet sediment) based on mean measured concentrations and ≥ 28200 µg a.s./kg dry sediment (≥ 16900 µg a.s./kg wet sediment) based on initially measured concentrations.

CA 8.2.6 Effects on algal growth

CA 8.2.6.1 Effects on growth of green algae

EU agreed endpoints for the freshwater green alga *Pseudokirchneriella subcapitata* are available, thus no further studies are required.

CA 8.2.6.2 Effects on growth of an additional algal species

The following 96 hour algal study on the freshwater diatom *Navicula pelliculosa* performed with the active substance alpha-cypermethrin is not required for registration in the EU. The study was conducted for U.S. registration purposes and has not been evaluated previously on EU level. In accordance to the EFSA Aquatic Guidance Document (EFSA, 2013) and OECD guideline 201 (2001) the 72 h endpoints obtained in the 96 h study are considered as relevant endpoint for the aquatic risk assessment, therefore both the 72 h and 96 h endpoints are reported in the study summary below.

Report:	CA 8.2.6.2/1 Hoffmann F., 2009a Effect of BAS 310 I (Reg.No. 4078193) on the growth of the fresh water diatom Navicula pelliculosa - A limit test 2009/1109081
Guidelines:	OECD 201, EPA 850.5400
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 96-hour static toxicity limit test, the effect of alpha-cypermethrin on the growth of the freshwater diatom *Navicula pelliculosa* was investigated. Due to its poor solubility in water the test substance was applied as pure centrifuged stock solution at a geometric mean measured test concentration of 70.3 µg a.s./L. Assessment of growth was conducted 24 h, 48 h, 72 h and 96 h after test initiation.

The biological results are based on the geometric mean measured concentration of the test item. No morphological effects on algae were observed in the control and at the tested treatment concentration. Furthermore, no statistically significant differences of growth and yield compared to the control were observed after exposure over 96 hours.

In a 96 hour algal toxicity limit test with *Navicula pelliculosa,* the E_rC_{50} and the E_yC_{50} for alpha-cypermethrin were both determined to be > 70.3 µg a.s./L after exposure over 72 and 96 hours, based on geometric mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I; Reg. No. 4 078 193), batch no. COD-000595; purity: 99.2 ± 1.0%.

B. STUDY DESIGN

Test species: Freshwater diatom, *Navicula pelliculosa*, strain UTEX 674, stock originally obtained from the "UTEX Culture Collection of Algae", University of Texas, Austin, USA.

Test design: Static system; test duration 96 hours; limit test: 1 test concentration plus a control; due to the poor water solubility of the test item a stock solution was prepared, constantly stirred for 24 hours and centrifuged to remove undissolved particles; the centrifuged stock solution was used for the limit test; 6 replicates for the test item and 10 replicates for the control; daily assessment of growth.

Endpoints: EC_{50} with respect to growth rate and yield after exposure over 72 hours and 96 hours.

Test concentrations: Control (dilution water), pure centrifuged stock solution: 70.3 µg alpha-cypermethrin/L (geometric mean measured).

Test conditions: 100 mL dimple flasks; test volume 60 mL; nutrient solution according to OECD 201; pH 8.1 at test initiation and pH 8.36 - 8.41 at test termination; temperature: 22 ± 1 °C; initial cell densities 1 x 10^4 cells/mL; continuous light at approx. 8000 lux; constant shaking at 135 rpm.

Analytics: Analytical verification of test item concentrations was conducted using a GC-method with MS detection.

Statistics: Descriptive statistics; Student t-test ($\alpha = 0.05$) for determination of the NOEC (72 h and 96 h) values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in the tested concentration at the beginning and at the end of the test. The analyzed contents of alpha-cypermethrin ranged from 44.4 to 64.3 µg a.s./L at test initiation and from 56.5 to 116 µg a.s./L at test termination. The resulting geometric mean measured concentration of alpha-cypermethrin was 70.3 µg a.s./L and is used for the following biological results.

Biological results: No morphological effects on algae were observed in the control and at the tested treatment concentration. Furthermore, no statistically significant differences of growth and yield compared to the control were observed after exposure over 96 hours (Student t-test; $\alpha = 0.05$).The effects on algal growth are summarized in Table 8.2.6.2-1.

Table 8.2.6.2-1: Effect of alpha-cypermethrin on the growth of the freshwater diatom *Navicula pelliculosa*

Concentration [µg a.s./L] (geometric mean measured)	**70.3**
Inhibition in 72 h (growth rate) *	-0.1
Inhibition in 72 h (yield) *	-0.4
Inhibition in 96 h (growth rate)	0.1
Inhibition in 96 h (yield)	0.4
Endpoints [µg alpha-cypermethrin/L] (geometric mean measured)	
E_rC_{50} / E_yC_{50} (72 h & 96 h)	> 70.3
NOE_rC / NOE_yC (96 h)	≥ 70.3

* Negative values indicate stimulated growth compared to the control.

III. CONCLUSION

In a 96 hour algae toxicity limit test with *Navicula pelliculosa,* the E_rC_{50} and the E_yC_{50} for alpha-cypermethrin were both determined to be > 70.3 µg a.s./L after exposure over 72 and 96 hours, based on geometric mean measured concentrations.

The following 96 hour algal study on the freshwater blue-green alga *Anabaena flos-aquae* performed with the active substance alpha-cypermethrin is not required for registration in the EU. The study was conducted for U.S. registration purposes and has not been evaluated previously on EU level. In accordance to the EFSA Aquatic Guidance Document (EFSA, 2013) and OECD guideline 201 (2001) the 72 h endpoints obtained in the 96 h study are considered as relevant endpoint for the aquatic risk assessment, therefore both the 72 h and 96 h endpoints are reported in the study summary below.

Report:	CA 8.2.6.2/2 Hoffmann F., 2009b Effect of BAS 310 I (Reg.No. 4078193) on the growth of the blue-green alga Anabaena flos-aquae - A limit test 2009/1109080
Guidelines:	OECD 201, EPA 850.5400
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 96-hour static toxicity limit test, the effect of alpha-cypermethrin on the growth of the freshwater blue-green alga *Anabaena flos-aquae* was investigated. The test item concentration reflected the maximum solubility of the test item under test conditions and corresponded to a geometric mean measured test item concentration of 27.0 µg alpha-cypermethrin/L. Assessment of growth was conducted 24 h, 48 h, 72 h and 96 h after test initiation.

The biological results are based on geometric mean measured concentrations of the test item. No morphological effects on algae were observed in the control and the tested treatment concentration. Furthermore, no statistically significant differences of growth and yield compared to the control were observed after exposure over 96 hours.

In a 96 hour algae toxicity limit test with *Anabaena flos-aquae,* the E_rC_{50} and the E_yC_{50} for alpha-cypermethrin were both determined to be > 27.0 µg a.s./L after exposure over 72 and 96 hours, based on geometric mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I; Reg. No. 4 078 193), batch no. COD-000595; purity: 99.2 ± 1.0%.

B. STUDY DESIGN

Test species:	Freshwater blue-green alga, *Anabaena flos-aquae*, specification UTEX B 674, stock originally obtained from "UTEX Culture Collection of Algae", University of Texas, Austin, USA.
Test design:	Static system; test duration 96 hours; limit test: 1 test concentration plus a control; 6 replicates for the test item and 10 replicates for the control; the test item concentration reflects the maximum solubility of the test item under test conditions; daily assessment of growth.
Endpoints:	EC_{50} and NOEC with respect to growth rate and yield after exposure over 72 hours and 96 hours.
Test concentrations:	Control, pure centrifuged stock solution: 27.0 µg alpha-cypermethrin/L (geometric mean measured).
Test conditions:	100 mL dimple flasks; test volume 60 mL; nutrient solution according to OECD 201; pH 7.5 at test initiation and pH 7.24 - 7.30 at test termination; temperature: 24 ± 1 °C; initial cell densities 1 x 10^4 cells/mL; continuous light at approx.. 3500 lux; constant shaking at 170 rpm.
Analytics:	Analytical verification of test item concentrations was conducted using a GC-method with MS detection.
Statistics:	Descriptive statistics; Student t-test ($\alpha = 0.05$) for determination of the NOEC value.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of the test item concentrations was conducted in the tested concentration at the beginning and at the end of the test. The mean analyzed content of alpha-cypermethrin in the test item treatment was 28.0 µg/L at test initiation and 26.1 µg/L at test termination, resulting in a geometric mean measured concentration of 27.0 µg a.s./L. The following biological results are based on the geometric mean measured concentration.

Biological results: No morphological effects on algae were observed in the control and the tested treatment concentration. Furthermore, no statistically significant differences of growth and yield compared to the control were observed after exposure over 96 hours (Student t-test; $\alpha = 0.05$). The effects on algal growth are summarized in Table 8.2.6.2-2.

Table 8.2.6.2-2: Effect of alpha-cypermethrin on the growth of the freshwater blue-green alga *Anabaena flos-aquae*

2009/1109079
Guidelines: OECD 201, EPA 850.5400
GLP: yes
(certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 96-h static toxicity limit test, the effect of alpha-cypermethrin on the growth of the marine diatom *Skeletonema costatum* was investigated. The test item concentration reflected the maximum solubility of the test item under test conditions and corresponded to a geometric mean measured test item concentration of 33.4 µg alpha-cypermethrin/L. Assessment of growth was conducted 24 h, 48 h, 72 h and 96 h after test initiation.

The biological results are based on the geometric mean measured concentration of the test item. No morphological effects on algae were observed in the control group and at the tested concentration. After 96 hours of exposure, no statistically significant differences compared to the control were observed at the tested concentration of 33.4 µg a.s./L.

In a 96-h algae toxicity limit test with *Skeletonema costatum*, the E_rC_{50} and the E_yC_{50} of alpha-cypermethrin were both determined to be > 33.4 µg a.s./L after exposure over 72 and 96 hours, based on geometric mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I; Reg. no.: 4 078 193), batch no. COD-000595; purity: 99.2% ± 1%.

B. STUDY DESIGN

Test species: Marine diatom, *Skeletonema costatum*, specification: UTEX 2308; stock obtained from "UTEX Culture collection of Algae", University of Texas, Austin, USA.

Test design: Static system (96 hours); limit test: 1 test concentration plus a control; 6 replicates for the test item and 10 replicates for the control; the test item concentration reflects the maximum solubility of the test item under test conditions; daily assessment of growth.

Endpoints: EC_{50} and NOEC with respect to growth rate and yield after exposure over 72 hours and 96 hours.

Test concentrations: Control, pure centrifuged stock solution: 33.4 µg alpha-cypermethrin/L (geometric mean measured).

Test conditions: 100 mL Erlenmeyer dimple flasks; test volume: 60 mL; nutrient solution according to OECD 201; pH 8.1 at test initiation and pH 7.79 - 7.83 at test termination; temperature: 20 ± 1 °C; initial cell densities: 1 x 10^4 cells/mL; photoperiod: 14 hours light : 10 hours dark, light intensity: about 4400 lux, continuous shaking at 60 rpm.

Analytics: Analytical verification of test item concentrations was conducted using a GC method with MS detection.

Statistics: Descriptive statistics, Student t-test (α = 0.05) for determination of the NOEC (96 h) values.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of the test item concentrations was conducted in the tested concentration at the beginning and at the end of the test. The mean analyzed content of alpha-cypermethrin in the test item treatment was 34.6 µg/L at test initiation and 32.3 µg/L at test termination, resulting in a geometric mean measured concentration of 34.4 µg a.s./L. The following biological results are based on the geometric mean measured concentration.

Biological results: No morphological effects on algae were observed in the control group and at the tested concentration. After 96 hours of exposure, no statistically significant differences compared to the control were observed at the tested concentration of 33.4 µg a.s./L (Student t-test, α = 0.05). The effects on algal growth are summarized in Table 8.2.6.2-3.

Table 8.2.6.2-3: Effect of alpha-cypermethrin on the growth of the marine diatom *Skeletonema costatum*

Concentration [µg a.s./L] (geometric mean measured)	**33.4**
Inhibition in 72 h (growth rate) [%]	- 0.4
Inhibition in 72 h (yield) [%]	- 1.3
Inhibition in 96 h (growth rate) [%]	- 0.4
Inhibition in 96 h (yield) [%]	- 1.8
Endpoints [µg alpha-cypermethrin/L] (geometric mean measured)	
E_rC_{50} / E_yC_{50} (72 h & 96 h)	> 33.4
NOE_rC / NOE_yC (96 h)	≥ 33.4

* Negative values indicate stimulated growth compared to the control.

III. CONCLUSION

In a 96-h algae toxicity limit test with *Skeletonema costatum*, the E_rC_{50} and the E_yC_{50} of alpha-cypermethrin were both determined to be > 33.4 µg a.s./L after exposure over 72 and 96 hours, based on geometric mean measured concentrations.

CA 8.2.7 Effects on aquatic macrophytes

The following toxicity study on the aquatic plant *Lemna gibba* performed with the active substance alpha-cypermethrin is not required for registration in the EU. The study was conducted due to U.S. data requirements and has not been evaluated previously on EU level.

Report:	CA 8.2.7/1 Hoffmann F., 2009d Effect of BAS 310 I (Reg.No. 4078193) on the growth of Lemna gibba - A limit test 2009/1108874
Guidelines:	OECD 221, EPA 850.4400, ASTM E 1415-91
GLP:	yes (certified by Landesamt fuer Umwelt, Wasserwirtschaft und Gewerbeaufsicht, Mainz, Germany)

Executive Summary

In a 7-day static limit test, the effect of alpha-cypermethrin on the growth of the duckweed *Lemna gibba* was investigated. The test item concentration reflected the maximum solubility of the test item under test conditions and corresponded to a geometric mean measured test item concentration of 1.39 µg alpha-cypermethrin/L. Additionally, a dilution water control was set up. Assessment of plant growth and other effects was conducted 3, 5 and 7 days after test initiation. The percentage growth inhibition in the test item treatment, relative to the control, was calculated based on growth rates and final yield for the parameters frond number and plant dry weight.

The biological results are based on the geometric mean measured concentration of the test item. The duckweed population in the control vessels showed sufficient, exponential growth. No morphological effects on the duckweed were observed in the control and at the test item concentration of 1.39 µg a.s./L. There were no statistically significant effects on the growth of *Lemna gibba* compared to the control at the tested concentration of 1.39 µg a.s./L.

In a 7-day aquatic-plant limit test with *Lemna gibba,* both the E_rC_{50} and the E_yC_{50} values of alpha-cypermethrin based on frond number and dry weight were determined to be > 1.39 µg a.s./L, based on geometric mean measured concentrations.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I; Reg. no.: 4 078 193), batch no. COD-000595; purity: 99.2%.

B. STUDY DESIGN

Test species: Duckweed (*Lemna gibba* G3); inocula: 10 days old cultures; maintained in-house; stock obtained from "ÖkoTox Moser & Pickl GbR", Stuttgart, Germany.

Test design: Static system; test duration 7 days; limit test: 1 test item concentration plus a control with 6 replicates, respectively, 2 plants with 4 fronds and 1 plant with 3 fronds, total number of fronds at test initiation: 11 per replicate; assessment of growth and other effects on days 3, 5 and 7.

Endpoints: EC_{50} with respect to growth rate and yield after exposure over 7 days.

Test concentrations: Control (dilution water) and geometric mean measured test item concentration of 1.39 µg alpha-cypermethrin/L (reflects the maximum solubility of the test item under test conditions).

Test conditions: 400 mL glass flasks, test volume: 160 mL, 20 x-AAP medium, pH 7.50 - 7.51 at test initiation and pH 8.56 - 8.63 at test termination; mean water temperature: 24.3 °C, continuous light, light intensity: about 8200 lux.

Analytics: Analytical verification of the test item was conducted using a GC-method with MS-detection.

Statistics: Descriptive statistics, standard procedures.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of the test item concentration was conducted in the control and the test item treatment at the beginning and at the end of the test. The mean analyzed content of alpha-cypermethrin in the test item treatment was 2.45 µg/L at test initiation and 0.788 µg/L at test termination, resulting in a geometric mean measured concentration of 1.39 µg/L. The following biological results are based on the geometric mean measured concentration.

Biological results: The duckweed population in the control vessels showed exponential growth, increasing from 11 fronds per vessel to an average of 142.7 fronds per vessel in the control after 7 days, corresponding to a 13.0 x multiplication. The dry weight increased from 2.0 mg to an average of 21.2 mg per vessel in the control at test termination. No morphological effects on the duckweed were observed in the control and at the test item concentration of 1.39 µg a.s./L. There were no statistically significant effects on the growth of *Lemna gibba* compared to the control at the tested concentration of 1.39 µg a.s./L. Effects on growth rate and yield are summarized in Table 8.2.7-1.

Table 8.2.7-1: Effects of alpha-cypermethrin on the growth of duckweed *Lemna gibba*

Concentration [µg a.s./L] (geometric mean measured)	**Control**	**1.39**
Inhibition after 7 d [%] (growth rate based on frond no.)	--	0.6
Inhibition after 7 d [%] (growth rate based on dry weight)	--	0.6
Inhibition after 7 d [%] (yield based on frond no.)	--	1.9
Inhibition after 7 d [%] (yield based on dry weight)	--	1.6
	Endpoints [µg a.s./L] (geometric mean measured)	
E_rC_{50} / E_yC_{50} (7 d) based on frond no. and dry weight	> 1.39	

III. CONCLUSION

In a 7-day aquatic-plant limit test with *Lemna gibba,* both the E_rC_{50} and the E_yC_{50} values of alpha-cypermethrin based on frond number and dry weight were determined to be > 1.39 µg a.s./L, based on geometric mean measured concentrations.

CA 8.2.8 Further testing on aquatic organisms

The following outdoor mesocosm study performed with the solo-formulation BAS 310 55 I (containing 50.0 g alpha-cypermethrin/L, nominally) is provided in support of the aquatic risk assessment and has not been evaluated previously on EU level.

Guidelines:	SANCO/3029/99 rev. 4 (11 July 2000)
GLP:	yes (certified by Landesamt fuer Umwelt, Messungen und Naturschutz Baden Wuerttemberg, Karlsruhe, Germany)

Executive Summary

In a 12-weeks outdoor mesocosm study, the acute and chronic effects of the active substance alpha-cypermethrin (BAS 310 I; applied as solo-formulation BAS 310 55 I) on functional and structural parameters of aquatic ecosystems were investigated under field conditions in natural pond water. Mesocosms consisted of eighteen stainless steel enclosures each containing approx. 1600 L of water with a sediment layer. The test item was applied directly into the water column at nominal initial water concentrations of 0.12, 0.6, 3.0, 15, 30 and 90 ng a.s./L (corresponding to measured peak concentrations of 0.21, 0.87, 4.03, 17.0, 38.5 and 138 ng a.s./L) with two replicate enclosures per concentration. Four untreated enclosures were used as controls. All test item concentrations were applied twice (on May 09, 2012 and May 17, 2012), except for the 30 ng a.s./L treatment which was applied only once. The second application of 15 ng a.s./L was time-shifted (on May 25, 2012).. Post-application samplings and analysis of biota and physico-chemical parameters were conducted at weekly or bi-weekly intervals until 12 weeks after treatment. The effects monitored at the ecosystem level included functional parameters measured via physical-chemical water parameters and structural parameters such as diversity of species and effects on and recovery time of the communities of macrozoobenthos, emerging insects, zooplankton, phytoplankton and macrophytes..

The effects monitored at the population level included abundance of individual populations of phytoplankton, zooplankton and macrozoobenthos and recovery time of sensitive organisms.

Analyses of alpha-cypermethrin in water samples collected 1 to 3 h after application showed that peak concentrations were between 113% and 173% of the nominal alpha-cypermethrin concentrations. Therefore, the biological results are based on mean measured peak concentrations. No effects on any of the monitored population or community were observed at the three lowest test item concentrations 0.21, 0.87 and 4.03 ng a.s./L (class 1). Pronounced effects with recovery within 8 weeks after the first application (class 3A) were found at 17.0 ng a.s./L for the community structure and the total abundance of macroinvertebrates, for *Chaoborus* sp. as well as for some zooplankton populations (namely copepodites of Diaptomidae) and at 138 ng a.s./L for populations of emerging insects (based on Chaoboridae sp.). At 38.5 ng a.s./L (single application) the observed effects were very similar to the effects found after a double application of 17.0 ng a.s./L, except that no consistent effects on the total abundance of macroinvertebrates were observed but slight effects on the zooplankton community (class 2). After twofold application at 17.0 ng a.s./L and single application at 38.5 ng a.s./L, no effects on emerging insects, phytoplankton or macrophytes were observed. Pronounced effects without recovery within the test period (class 5B) were found at 138 ng a.s./L for the community structure and the populations of macroinvertebrates (based on total abundance of *Asellus aquaticus* and *Baetidae* sp.) and zooplankton (based on the copepodites of Diaptomidae). Furthermore, at 138 ng a.s./L, slight and short term increases in abundances of phytoplankton populations (based on *Cryptomonas erosa et ovata* and *Navicula pupula*) were observed (class 2+) whereas no effects on the community of emerging insects, on the community of phytoplankton or on macrophytes were observed (class 1).

The overall NOEC of this aquatic outdoor mesocosm study is 4.03 ng a.s./L (based on mean-measured peak concentration) as no consistent effects on any of the monitored endpoints were observed up to this concentration. Two applications of 17.0 ng a.s./L and one application of 38.5 ng a.s./L are defined as the study specific effect class 3A NOEAEC, since no long lasting effects were observed at these treatment levels.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 310 55 I, batch no. 101198; content of a.s.: alpha-cypermethrin (BAS 310 I, Reg. No. 4078193): 51.1 g/L (nominal: 50 g/L); density: 0.994 g/cm^3.

B. STUDY DESIGN

Test system: The mesocosm site is located on the grounds of 'Institut für Gewässerschutz' MESOCOSM GmbH, Homberg (Ohm), Germany. Outdoor mesocosm study was conducted in stainless-steel enclosures each with a diameter of approximately 143 cm (surface approx. 1.60 m^2) and a depth of approximately 150 cm. The nominal depth of the water body was 100 cm ± 10%, resulting in a total volume of approximately 1600 L. 18 stainless steel enclosures were pressed into the sediment of an artificial pond (diameter of approximately 7.7 m, water volume approx. 47,000 L) 49 days before the first test item application. 15 enclosures were selected for the use in the study. Because of an amendment two further enclosures were reintroduced in the study after the first application. The artificial pond was filled with sediment and water collected from a reference lake on-site. The pond sediment was placed in the artificial pond (10 - 15 cm) onto a layer of clay (5 - 10 cm). The organic matter content of the mixed sediment was 1.9%. Washed sand was added to achieve the optimum organic carbon content. The test system was established in March 2009, so the period for equilibration of the test system was about 38 months.
The test systems contained various naturally growing macrophytes (*Ceratophyllum demersum*, *Potamogeton natans*, *Chara intermedia*, *Zannichellia palustris*) of comparable density and composition per enclosure at the start of the exposure.

Test design: Static test system. The test item was applied twice to the outdoor mesocosm community with two replicate enclosures per concentration. Due to a calculation error of the analytical laboratory for preparation of the application solutions of the higher concentrations the application of 15 ng a.s./L was time-shifted and 30 ng a.s./L was only applied once. Four untreated enclosures were used as controls The test item was applied directly into the water column on May 09, 2012 and May 17, 2012. The second application for the treatment receiving 15 ng a.s./L was on May 25, 2012. The in-life phase was terminated 12 weeks after the first application. Water and sediment samples were taken from enclosures after applications at regular intervals for residue analysis. All enclosures were monitored for water parameters (temperature, oxygen concentration, pH, conductivity and nutrients), macrophytes, phytoplankton, zooplankton, emerging insects and macrozoobenthos at weekly or bi-weekly intervals. The biological samples were collected from the enclosures at regular intervals over the course of the study by depth-integrated sampling (zooplankton, phytoplankton), under water traps and netting (macroinvertebrates), emergence traps (emerging insects).

Endpoints:	NOEC and NOEAEC plus corresponding 'effect classes'; based on functional parameters (physical-chemical water parameters such as conductivity, pH, dissolved oxygen, DOC, nitrate, phosphate and ammonium), structural parameters (diversity of species and effects on and recovery time of the communities of macrozoobenthos, emerging insects, zooplankton, phytoplankton and macrophytes) and population effects (abundance of individual populations of macrozoobenthos, zooplankton and phytoplankton, recovery time of sensitive organisms).
Test concentrations:	0 (water control), 2.33, 11.7, 58.4, 291.8, 583.6 and 1750.6 ng BAS 310 55 I/L (nominal); equivalent to 0.12, 0.6, 3.0, 15, 30 and 90 ng alpha-cypermethrin/L (corresponding to measured peak concentrations of 0.21, 0.87, 4.03, 17.0, 38.5 and 138 ng a.s./L). Second application of 15 ng a.s./L (nominal) was time-shifted and the 30 ng a.s./L treatment (nominal) was applied only once.
Test conditions:	The test was performed under outdoor conditions. Climatic conditions and water parameters were recorded throughout the conduct of the study.
Analytics:	Test water and sediment samples collected at various time points from the mesocosm enclosures were analyzed for alpha-cypermethrin concentrations using GC/MS(NCI) after liquid/liquid partition (water) and extraction/partition (sediment).
Statistics:	Descriptive statistics; multiple comparison test by Dunnett ($\alpha = 0.05$) to determine the NOEC values; diversity analysis by calculation of the Shannon-Index and Evenness; similarity analysis using Steinhaus´ and Stander´s index; calculation of Principal Response Curves (PRC) as a multivariate approach to analyze and visualize effects on the community level. The program Community Analysis V4.3 (CA) was used for the calculations of effects (NOECs, diversity indices). The PRC analysis and the Redundancy Analysis (RDA) and Principal Component Analysis (PCA) were performed using CANOCO 4.5 (Biometrics Plant Research International, Wageningen, The Netherlands). Observed effects were classified according to the scheme suggested in the EU Guidance Document on Aquatic Ecotoxicology (SANCO 2002) and the refinement suggested by de Jong et al. (2008) in order to facilitate the estimation of the study specific NOEC and NOEAEC.

II. RESULTS AND DISCUSSION

Analytical measurements:

Analyses of alpha-cypermethrin in water samples collected 1 to 3 hours after application showed that peak concentrations were between 113% and 173% of the nominal alpha-cypermethrin concentrations. Therefore, the biological results are based on the mean measured peak concentrations. Alpha-cypermethrin dissipated fast from the water phase with a DT_{50} of ca. 24 h. The concentration of alpha-cypermethrin in sediment samples of control and treatments was below the LoQ (0.1 µg a.s./kg wet weight), indicating the decline of alpha-cypermethrin in the water phase is probably due to hydrolytic degradation and not to adsorption and sedimentation.

Biological results:

Functional parameters

All physical and chemical parameters (*e.g.* pH 8.71 - 10.05; conductivity: 183 - 255 µS/cm at 50 cm below water surface) were within the range of mesotrophic natural pond water during the study. Water temperatures ranged from around 11.5 °C (April) to around 21 °C (July) during the study. No treatment related effects on pH, oxygen levels or conductivity were observed (Dunnett`s test, $\alpha = 0.05$). Furthermore, there were no apparent treatment related effects in the measured nutrient parameters like water hardness (usually 2.6 - 5.7°dH with a trend to decrease to values around 3°dH at the end of the study), nitrate (always < 0.4 mg/L), and ammonium (always < 0.1 mg/L). The total phosphate concentration of the water was usually around or below 0.2 mg/L with a general trend to increase at the end of the study. The maximum concentration found was 1.0 mg/L.

Structural parameters

Macroinvertebrates

In total, 34 taxa respectively stages were identified in the 176 macroinvertebrates samples. The macroinvertebrates were dominated by the isopod *Asellus aquaticus*, mayflies (Ephemeroptera, mostly Baetidae), the phantom midge *Chaoborus* and flatworms of the order Tricladida.

No adverse direct or indirect effects of the test item were found either on the community or on the population level of the macroinvertebrates at the three lowest treatment levels of 0.21, 0.87 and 4.03 ng a.s./L (class 1). Pronounced effects on the community structure, the total abundance of macroinvertebrates and the *Chaoborus* population were demonstrated at 17.0 ng a.s./L. Since these endpoints recovered within 8 weeks after the first application, the effects at 17.0 ng a.s./L were classified as class 3A. At 138 ng a.s./L no full recovery regarding the community structure, the total abundance and the populations of *Asellus aquaticus* and Baetidae / Sum Ephemeroptera took place during the study. Thus, the effects at the highest concentration are considered to be class 5B effects.

After a single application of 38.5 ng a.s./L effects of class 3A (community structure and *Chaoborus* sp.) were observed.

Emerging insects
In total, 16 taxa of eight different orders were found in the 223 samples of the emerging insects. Since no treatment related effects on the community and the population level of emerging insects were found at 0.21, 0.87, 4.03, 17.0 (twofold application) and at 38.5 ng a.s./L (single application), effect class 1 can be assigned to all of these treatment levels.
At 138 ng a.s./L no effects were observed on community structure and total abundance. For the population of Chaoboridae a pronounced decrease with recovery within 8 weeks after the first application was found at 138 ng a.s./L, resulting in a classification to effect class 3A.

Zooplankton
Species of three classes (Insecta, Crustacea and Rotatoria) were present in the 272 zooplankton samples. 13 different taxa respectively life stages (nauplia, copepodites and adults of copepods) of crustaceans were identified and 17 different taxa of rotifers.
No direct or indirect effects on zooplankton community or at the population level were observed up to a concentration of 4.03 ng a.s./L (class 1). At 17.0 ng a.s./L no effects on the community, but slight (*Chydorus sphaericus*) respectively pronounced effects with recovery within 8 weeks after the first application (Diaptomidae copepodites) on the zooplankton populations were found. Based on the effects on Diaptomidae copepodites these effects are classified as class 3A.
At 138 ng a.s./L no effects on the number of taxa or the Shannon index, but short term effects on total abundance and diversity (Evenness) were observed (class 2). Pronounced long term effects on the community structure were indicated by similarity and ordination analyses (PCA). As full recovery was not proven for two consecutive sampling dates, these effects are considered as class 5B effects. In addition, the effects on the zooplankton populations were also rated as class 5B effects based on Diaptomidae copepodite.
At 38.5 ng a.s./L (single application) slight temporary effects on the zooplankton community (Stander`s index) were observed (class 2), but pronounced short term effects on Diaptomidae were demonstrated. Thus, the effects on the zooplankton populations are assigned as class 3A.

Phytoplankton
The analysis with inverted microscopy of the 160 phytoplankton samples resulted in 140 taxa belonging to nine different classes.
Regarding the phytoplankton community and populations no direct or indirect effects were observed after twofold application at up to 17.0 ng a.s./L and after single application at 38.5 ng a.s./L (class 1).
At the highest treatment level (138 ng a.s./L) no effects on the community structure or total abundance were observed (class 1), but slight short term, positive, effects on the populations of *Cryptomonas erosa + ovata* and *Navicula pupula* occurred on two consecutive samplings days at 138 ng a.s./L, resulting in a class 2 effect.

Macrophytes
The following macrophyte species were found: *Ceratophyllum demersum*, *Potamogeton natans* and *Zannichellia palustris*. The algae *Chara intermedia* and filamentous algae were also considered within the functional group of macrophytes. The percentage of coverage of all macrophytes and of each species was comparable at all treatment levels. No unusual observations were made.

A summary of the effect classes for the different types of endpoints and the concentrations tested is provided in Table 8.2.8-1 below. The classes on the taxon level are based on the most sensitive taxon found in the community.

Table 8.2.8-1: Summary of effect classes # in the outdoor mesocosm study with alpha-cypermethrin

Endpoint	Mean-measured peak concentration [ng a.s./L] *					
	0.21	0.87	4.03	17.0	138	38.5
Macroinvertebrates						
Community structure	1	1	1	3A	5B	3A
Abundance of populations	1	1	1	3A	5B	3A
Emerging insects						
Community structure	1	1	1	1	1	1
Abundance of populations	1	1	1	1	3A	1
Zooplankton						
Community structure	1	1	1	1	5B	2
Abundance of populations	1	1	1	3A	5B	3A
Phytoplankton						
Community structure	1	1	1	1	1	1
Abundance of populations	1	1	1	1	2+	1
Macrophytes						
Coverage	1	1	1	1	1	1
Study			NOEC	NOEAEC		NOEAEC

* Note: 0.22, 0.87, 4.03, 17.0, and 138 ng a.s./L were applied twice, 38.5 ng a.s./l was applied once.

Classes according to the Guidance Document on Aquatic Ecotoxicology (SANCO 2002) and de Jong et al. (2008): 1 = effects could not be demonstrated; 2 = slight and/or temporary effects on single sampling dates; 3A = pronounced short-term effect with recovery within 8 weeks after first application or total period of effects < 8 weeks; 5B = pronounced effects without full recovery within the study. A '+' indicates an increase of abundance.

III. CONCLUSION

The overall NOEC of this aquatic outdoor mesocosm study is 4.03 ng a.s./L (based on mean-measured peak concentration) as no consistent effects on any of the monitored endpoints were observed up to this concentration. Two applications of 17.0 ng a.s./L or one application of 38.5 ng a.s./L are defined as the study specific effect class 3A NOEAEC, since no long lasting effects were observed at these treatment levels.

The following summary of a Review of available mesocosm studies conducted with alpha-cypermethrin is provided in support of the aquatic risk assessment and has not been evaluated previously on EU level.

Report: CA 8.2.8/3
Janz P., 2015a
A critical review of available mesocosm studies with Alpha-Cypermethrin
2014/1102014
Guidelines: none
GLP: no

Executive Summary

In the period 1997 to 2012, nine aquatic field studies (*i.e.* mesocosms) applying different exposure regimes were conducted at three different sites across Germany. In this review each of these studies was evaluated using a unified set of criteria. This chapter brings together all results in a weight of evidence approach, considering the consistency in results and reliability of the studies.
The results and final conclusions of the evaluated mesocosm studies appeared highly consistent (see Table 8.2.8-2). The effects after one, two and three applications of alpha-cypermethrin are summarized in the following and appropriate endpoints are proposed.

One application
In studies dealing with effects after a single application of alpha-cypermethrin no effects (class 1) on any of the monitored endpoints were found up to a concentration of 3 ng a.s./L. In the single application study with a study specific NOEC of 0.6 ng a.s./L (Dawo 2005a), 3 ng a.s./L was not applied and 15 ng a.s./L was the next higher treatment level. **Thus, 3 ng a.s./L is considered as a fully supportable overall $NOEC_{mesocosm}$ for alpha-cypermethrin after a single application.** Further, this value needs to be compared with (and adjusted to) the two application NOEC, as the latter cannot be higher.

Huber et al. 2000a, Huber et al. 2000b, Grünwald 2003, Dawo 2005a and Stegger and Janz 2014 showed that no direct long-lasting effects (class 3A) occurred after a single application of 12, 15, 15, 15 or 38.5 ng a.s./L. Thus, in consideration of the concentration in the next higher treatment level (*i.e.* 60 or 75 ng a.s./L) and the reliability of 1 for the Stegger and Janz (2014) study, **38.5 ng a.s./L is regarded as an overall and consistent $NOEAEC_{mesocosm}$ for alpha-cypermethrin after a single application.**

At the treatment level of 12, 15 or 38.5 ng a.s./L the effects on macroinvertebrates in the studies were comparable. In each study the phantom midge *Chaoborus* was the most sensitive organism. The effects on the *Chaoborus* populations as well as the impacts on the macroinvertebrate communities were rated as class 3A effects in each study. The effects on zooplankton at these concentrations differed slightly between the studies. Class 3A effects on the zooplankton community were observed in two studies (Huber et al. 2000b and Dawo 2005a). Class 2 effects on the zooplankton community were found in three studies (Huber et al. 2000a, Grünwald 2003, Stegger and Janz 2014). Changes in the zooplankton community structures were mainly indirect effects and due to lower abundance of *Chaoborus*, resulting in reduced predation pressure. The most sensitive group of organisms belonging to the zooplankton community was Copepoda. Indirect long lasting effects (class 5A+) were revealed at 15 ng a.s./L in Dawo 2005a. This isolated observation was not considered to disagree with the above mentioned overall $NOEAEC_{mesocosm}$ since the effect was indirect, not ecologically relevant (had no influence on any other endpoint) and the effect duration could not be confirmed in any of the other evaluated studies (even after multiple applications of alpha-cypermethrin they did not last longer than 8 weeks, Huber et al. 2001 and Dawo 2005b). No effects on copepods at 15 ng a.s./L were found in Huber et al. (2000a and 2000b) and Grünwald (2003; note, the classification of effects on zooplankton populations into class 3A was based on *Chaoborus* in this study). Class 3A effects on copepods were also described by Stegger and Janz (2014). The impacts on phytoplankton, the food source of zooplankton, were comparable in all studies. Effects on the phytoplankton community were shown in none of the studies at 12, 15 or 38.5 ng a.s./L. However, at these concentrations short term effects (class 2) on phytoplankton populations were found in Huber et al. (2000b), Dawo (2005a) and Stegger and Janz (2014), while no effect on phytoplankton populations were revealed in Grünwald (2003). Huber et al. (2000a) did not analyse phytoplankton at the population level.

Class 5 effects were always measured at the next higher tested treatment level above 12, 15 and 38.5 ng a.s./L, respectively. These concentrations were 60 (Huber et al. 2000a), 75 (Huber et al. 2000b, Grünwald 2003 and Dawo 2005) and two applications of 138 ng a.s./L (Stegger and Janz 2014).

Two applications

No effects (class 1) on any of the monitored endpoints were demonstrated after a double application of alpha-cypermethrin up to a concentration of 4.03 ng a.s./L in Stegger and Janz (2014). A reliability index of 1 was assigned to this study. No $NOEC_{mesocosm}$ was found in the study of Sevim 2012, in which only one concentration (20 ng a.s./L) was tested. Jordan (2012) and Sippenhauer (2012) determined a $NOEC_{mesocosm}$ of 0.6 ng a.s./L. However, the findings of this study are not reliable (Ri = 3, low acceptability). Therefore, the derivation of an overall $NOEC_{mesocosm}$ is based on the $NOEC_{mesocosm}$ specified in the reliable study by Stegger and Janz (2014). Thus, **4.03 ng a.s./L is considered as a fully supportable overall $NOEC_{mesocosm}$ for alpha-cypermethrin after two applications with an interval of approximately one week**.
This value would then also be applicable for a single application.

In the reliable study conducted by Stegger and Janz (2014) the study specific $NOEAEC_{mesocosm}$ was determined as 17 ng a.s./L. The effects after a double application of the nominal concentration of 20 ng a.s./L described by Sevim 2012 were also rated as class 3A effects. However, as the effects in Sevim (2012) cannot be related to measured concentrations and consequently the reliability of this study is rated as 3 (not reliable), the test concentration of 20 ng a.s./L is not considered as a fully supportable $NOEAEC_{mesocosm}$. The same applies for the $NOEAEC_{mesocosm}$ of 135 ng a.s./L as derived from Jordan (2012) and Sippenhauer (2012). Consequently, **17 ng a.s./L is regarded as a fully supportable overall $NOEAEC_{mesocosm}$ for alpha-cypermethrin after two applications with an interval of approximately one week.**

The effects described by Stegger and Janz (2014) after two applications of 17 ng a.s./L with a one week interval were very similar to those found after one application of 12, 15 and 38.5 ng a.s./L. Class 3A effects were observed for the macroinvertebrate community, for *Chaoborus* as well as for zooplankton populations, namely copepodites. In contrast to the results of the single application studies, at 17 ng a.s./L no effects on the zooplankton community were described by Stegger and Janz (2014). *Chaoborus*, the species which caused the indirect effects on the zooplankton community, was by far less dominant (15.5% of macroinvertebrates) in the test system used by Stegger and Janz (2014) compared to the ponds in the studies performed at TU Munich (e.g. 68% of macroinvertebrates in Dawo 2005a). As a consequence, the influence of *Chaoborus* on the zooplankton community was clearly much weaker in Stegger and Janz (2014). This is probably the reason why no indirect effects on the zooplankton community were shown at 17 ng a.s./L in Stegger and Janz (2014). No effects on emerging insects, phytoplankton or macrophytes were found by Stegger and Janz (2014) at 17 ng a.s./L. In the non reliable study performed by Sevim (2012) which focused on the population dynamics of *Chaoborus*, class 3A effects were observed after two applications of 20 ng a.s./L at an interval of two weeks. In the non-reliable study of Jordan (2012) and Sippenhauer (2012) the effects were classified as 3A up to and including a concentration of 135 ng a.s./L.
In Stegger and Janz (2014) class 5 effects on macroinvertebrates and zooplankton were measured at the next higher treatment level (138 ng a.s./L).

Three applications

Both studies with a triple exposure regime (Huber et al. 2001 and Dawo 2005b) were scientifically not reliable (Ri 3) due to lacking analytical verification of nominal concentrations. Therefore, the results of these studies should be interpreted with care and a fully supportable overall $NOEC_{mesocosm}$ and $NOEAEC_{mesocsm}$ could not be defined with reasonable certainty for three applications. However, the initial effects during the first days after application in both studies were perfectly in line with the other mesocosm studies (Huber et al. 2000a and 2000b, Grünwald 2003 and Stegger and Janz 2014), providing some evidence that the target concentrations were achieved. Huber et al. 2001 (three applications at an interval of two weeks) as well as Dawo 2005b (three applications at an interval of three weeks) determined 0.6 ng a.s./L to be the study specific NOEC. Since 3 ng a.s./L was not applied in these studies, it remains unclear, if this concentration is also a valid NOEC after triple application of alpha-cypermethrin.

In both studies pronounced effects with recovery within 8 weeks after the last application (class 3B) were detected for *Chaoborus* and the macroinvertebrate communities at 15 ng a.s./L. (changes in the macroinvertebrate community were mainly due to the effects on *Chaoborus*). The effects on *Chaoborus* and the macroinvertebrate community changed from class 3A (recovery within 8 weeks after the first application) to class 3B (recovery within 8 weeks after the last application), when 15 ng a.s./L of alpha-cypermethrin was applied three times instead of one or two times with a one week interval. As a consequence, *Chaoborus* populations and the macroinvertebrate communities should have recovered within four weeks and two weeks after the last application, respectively, for these effects to be classified into class 3A. Obviously, this time frame is too short for complete recovery of these endpoints after exposure to 15 ng a.s./L.

As a result of the longer lasting effects on *Chaoborus*, the indirect effects on zooplankton were stronger and also longer lasting after three applications compared to one or two applications. The effects on the zooplankton community in Huber et al. (2001) were classified as 3A and in Dawo (2005b) as 3B. Furthermore, the indirect effects on zooplankton populations were rated as class 3B based on planktonic arthropods and copepods in Huber et al. (2001) and on copepods in Dawo (2005b), respectively. Effects on the phytoplankton community were not found in these studies. Dawo (2005b) described slight effects on phytoplankton populations.

Table 8.2.8-2: Effect class concentrations [ng a.s./L] of the most sensitive endpoints in aquatic outdoor mesocosm studies with alpha-cypermethrin.

The effect classes are expressed in terms of nominal concentrations and measured mean peak concentrations in Stegger and Janz (2014). Ri = Reliability index (determined according to de Jong et al. 2008, 1 = reliable, 2 = less reliable, 3 = not reliable)

Exposure regime	Effect class 1	Effect class 2	Effect class 3A	Effect class 3B	Effect class 5	Reference	Ri
Single	3	-	12		60	Huber et al. 2000a	2

The phantom midge *Chaoborus*

The phantom midge *Chaoborus* was the most sensitive organism in all evaluated mesocosm studies. Therefore, the effects on this genus are discussed in detail in this section.

As mentioned above, up to a concentration of 4.03 ng a.s./L no effects on *Chaoborus* populations were observed in the evaluated mesocosm studies. Pronounced effects on *Chaoborus* at 12, 15, 20 or 38.5 ng a.s/L were described in each evaluated mesocosm study. Considering only the period after the last application, it appears, that it makes no difference for the effect duration, how often alpha-cypermethrin was applied in the weeks before the last application (if alpha-cypermethrin is applied at an approximately one week interval). In the single application studies the effects on *Chaoborus* lasted four weeks (Huber et al. 2000b and Grünwald 2003), five weeks (Huber 2000a and Dawo 2005a) and six weeks (Stegger and Janz 2014) after an application of 12, 15 or 38.5 ng a.s./L, respectively. In the two applications study the effects on *Chaoborus* lasted five weeks after the second application of 17 ng a.s./L (Stegger and Janz 2014). The less reliable studies conducted by Sevim (2012) and Jordan (2012) and Sippenhauer (2012) confirm this observation. Three applications of 15 ng a.s./L caused effects on *Chaoborus*, which lasted four weeks (Dawo 2005) and five weeks (Huber et al. 2001) after the third application. The time needed for recovery therefore complies with approximately one generation time of *Chaoborus* (six to seven weeks, Sevim 2012). The finding that the time needed for recovery seems to be independent from the number of previous applications with a one week interval, can be explained by the short dissipation time of alpha-cypermethrin in water (Huber et al. 2000b and Stegger and Janz 2014, respectively). Assuming first order kinetics for dissipation and using the DT_{50} of 1 d (Stegger and Janz, 2014, Huber et al. 2000b), the concentration of alpha-cypermethrin after an application of 15 ng a.s./L would be below the NOEC for *Chaoborus* (3 ng a.s./L) after 2.5 d. Since the concentration of alpha-cypermethrin is expected to be negligible one week after the first application of 15 ng a.s./L, there is no build up of alpha-cypermethrin after the second application of 15 ng a.s./L. Therefore, the peaks are toxicologically independent. Assuming a recovery time of six weeks, *Chaoborus* would probably recover within eight weeks after the first application (effect class 3A), if 15 ng a.s./L was applied three times at intervals of one week. Thus, 15 ng a.s./L is likely to be also an appropriate $NOEAEC_{mesocosm}$ for three applications with an interval of approximately one week.

In discussing the effects on *Chaoborus* populations, it is important to consider all factors affecting recovery. The recovery process of *Chaoborus* populations is influenced by the following aspects (based on Sevim 2012, Janz 2014; BASF DocID 2014/1102016) and findings in the review report):

- magnitude of the effect (to what extent is the population impacted)
- dissipation time of the substance in water (e.g. degradation and adsorption) (alpha-cypermethrin: DT_{50} ~ 1 d)
- generation time (depends on temperature, light period and food availability) (usually five to eight weeks during the growing season in Germany)
- number of generations per season (usually three generations in Germany)
- immigration / emigration of flying imagines (availability of unexposed waters)
- oviposition success
- population density (reduced density results in lower mortality due to less cannibalism)
- food availability (presence of prey)

Most of the above listed factors are depending on the season. Therefore the season, in which the test item is applied, should be taken into account. To ensure the possibility of recovery by recolonization, alpha-cypermethrin should be applied early enough in the year. During spring and early summer the conditions are best for recovery. Later in the year the number of flying imagines is usually too low for a complete recovery.

The immigration rate of flying imagines is enhanced by the availability of unexposed waters in the vicinity of the treated area. In each of the reliable evaluated mesocosm studies (except in Sevim 2012) unexposed waters (i.e. the control ponds) were available. However, selection of the water body for oviposition is primarily a function of fish abundance and distance from the site of emergence (Berendonk, 1999; Berendonk and Bonsall, 2002). In the cited papers it has been shown that female imagines of *C. crystallinus* disperse over great distances to find fish-free waterbodies to oviposit and colonize these. Therefore, population recovery in water bodies receiving drift entry of alpha-cypermethrin would also be expected when sources of *C. crystallinus* (such as unexposed waters) are not in the direct vicinity. This is supported by the results of Sevim (2012) which indicated that recovery is also possible in isolated ponds.

The following summary of a modelling study for phantom midge *Chaoborus* sp. population after treatment with alpha-cypermethrin is provided in support of the aquatic risk assessment and has not been evaluated previously on EU level.

Report: CA 8.2.8/4
Strauss T., 2015a
An individual based population model for the phantom midge Chaoborus crystallinus to simulate effects and recovery under Alpha-Cypermethrin (BAS 310 I) exposure
2014/1162681
Guidelines: none
GLP: no

Executive Summary

In this study, the FOCUS R3 stream scenario (late application date) with a twofold application of 10 g alpha-cypermethrin per ha (*i.e.* 200 mL BAS 310 55 I/ha) to leafy vegetables has been selected for modeling. Potential impacts on the population of the phantom midge *Chaoborus crystallinus* under realistic outdoor field conditions were assessed using a combination of different mitigation measures (i.e. buffer zones and drift reducing nozzles).

For this purpose, an individual based population model for *Chaoborus crystallinus* is used. The ecological model has been previously parameterized and intensively tested using large datasets from the laboratory as well as outdoor micro- and mesocosms. The complete life-cycle for *Chaoborus* populations was simulated depending on food conditions, water temperature and photoperiod. The model integrates density-dependent processes as well as immigration and emigration rates of the adults.

Further, a toxicokinetic/toxicodynamic (TKTD) effect model (GUTS approach) was used for the simulation of uptake and elimination rates of alpha-cypermethrin and the prediction of mortality from time-variable exposure, which was successfully coupled with the *Chaoborus* population model. With this modelling approach it is possible to extrapolate effect data from laboratory to field conditions such as outdoor studies (e.g. mesocosm and microcosm studies) without further model calibrations.

The model was tested against control data from several outdoor mesocosm studies first. The biological part of the IBM *Chaoborus* model proved suitable to reproduce the case specific as well as more principle population patterns as found in the mesocosm field studies.
Secondly, the model was tested against three alpha-cypermethrin mesocosm studies. The combination of the *Chaoborus* model and the GUTS model allowed a precise prediction of the impact of alpha-cypermethrin on *Chaoborus crystallinus* populations.
This was demonstrated for a large number of alpha-cypermethrin concentrations and different application patterns (single application in study AL-560-023, two applications in study 2014/1102015, and three applications in study AL-560-056), covering a wide concentration range from 0.06 ng/L to 1.875 µg/L.
The results showed a good match between simulations and measurements for the larval abundances as well as the emergence rate of the adults. This applies also to the timing and magnitude of the toxic effects, and the subsequent degree of recovery.
Finally, simulations with several FOCUS exposure scenarios were conducted to assess the effect size and the duration of the effects under semi-field conditions for *Chaoborus crystallinus*. The ecological scenario was defined as a mesocosm facility with treated and untreated (control) populations, as was used for the model testing previously.
Both, exposure concentrations and water temperatures were derived from the FOCUS R3 scenario.

In summary, the FOCUS R3 step 3 scenario (maximum peak height: 0.042 µg/L) caused stronger effects of longer duration than the FOCUS R3 step 4 scenarios that included mitigation measures (maximum peak heights ranging from 0.0014 to 0.0146 µg/L). In all cases effects lasted shorter than 8 weeks after the exposure started.

The following investigation of phantom midge population development in mesocosm studies is provided in support of the aquatic risk assessment and has not been evaluated previously on EU level.

Report: CA 8.2.8/5
Janz P., 2014a
Phantom midge (Chaoborus spp.) population development in mesocosm studies
2014/1102016
Guidelines: none
GLP: no

Executive Summary

Aquatic mesocosms (model ecosystems) are frequently used to refine aquatic risk assessments when a potential risk is indicated by lower tier studies (e.g. laboratory single species tests). One of the species typically occurring in mesocosms is the phantom midge *Chaoborus* spp.. As top predators in fish-free mesocosm studies chaoborids play a key role in limnetic food webs. Besides they are sensitive to insecticides, especially pyrethroids. For a correct evaluation of mesocosm data a profound knowledge of the biology of the organisms of interest is essential.

Based on a large data pool (data from 19 mesocosm studies, all of which were conducted in the same test system over a period of 15 years) this study provides information on *Chaoborus* population dynamics, their life cycle, the natural variability of *Chaoborus* populations and their influence on the zooplankton community structure. The data of untreated enclosures from 19 mesocosm studies was used to examine the population dynamics of *Chaoborus* and the inter-replicate and temporal variability of *Chaoborus* populations. For the analysis of the influence of *Chaoborus* on the zooplankton community structure, the enclosures in which direct effects exclusively on *Chaoborus* occurred (and consequently potential indirect effects on prey species and competing species) were included additionally.

The composition of the *Chaoborus* populations in the untreated enclosures analyzed in the present study varied significantly between the years. The variation in the *Chaoborus* population structure between the seasons (i.e. within a year) was even higher than between years. It was shown that in the studied test system there usually were three *Chaoborus* generations per year (from the end of April to the beginning of August), each lasting four to six weeks. Calculations of Minimum Detectable Differences (MDDs) showed that the inter-replicate variability was sufficient low in order to reveal population relevant effects of chemicals on *Chaoborus* in mesocosm studies that follow common principles of design and evaluation. Ordination analysis revealed that *Chaoborus* larvae seem to promote high densities of rotifers and reduce the abundance of small crustaceans (nauplii larvae, copepods and small cladocerans).

In the meantime, this report has been published in the peer-reviewed literature as: Janz P., Weltje L., Ebke K.P., Dawo U. 2015. Temporal population dynamics of the phantom midge *Chaoborus crystallinus* and its influence on the zooplankton community. Hydrobiologia 770(1): 273–287.

Analysis of the raw data of 19 mesocosm studies showed that the composition of *Chaoborus* populations varied significantly between the years with the variation in the *Chaoborus* population structure between the seasons (*i.e.* within a year) being higher than between years. The present study confirmed that population relevant effects of chemicals on *Chaoborus* will be picked up in mesocosm studies that follow common principles of design and evaluation. Furthermore, the study revealed that *Chaoborus* larvae seem to promote high densities of rotifers and reduce the abundance of small crustaceans.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Not specified in the study report (data from untreated mesocosm enclosures was used).

B. STUDY DESIGN

Data source: Raw data of 19 mesocosm studies, conducted at TU Munich, Germany in the period between 1999 and 2012.
The data of untreated enclosures was used to examine the population dynamics of *Chaoborus* and the inter-replicate and temporal variability of *Chaoborus* populations. For the analysis of the influence of *Chaoborus* on the zooplankton community structure, the enclosures in which direct effects exclusively on *Chaoborus* occurred (and consequently potential indirect effects on prey species and competing species) were included additionally.

Test system: 11 structurally identical ponds: stainless steel ponds (29 000 L, diameter 5 m, height 1.5 m) with 1 mm black polyethylene foil, the ponds were embedded in the ground at a depth of 1 m; the water surface was positioned approximately at ground level, 20 cm sediment layer (natural sediment obtained from nearby water bodies and soil material obtained during construction of the ponds); 600 - 750 L stainless steel enclosures (diameter: 0.9 - 0.95 m, height: 1.3 - 1.5 m) were introduced into the ponds at least four weeks before the beginning of each mesocosm study.
Macroinvertebrates, zooplankton and phytoplankton were introduced into the ponds with sediment and ditchwater.
Macrophyte species planted: *Myriophyllum spicatum*, *Potamogeton natans*, *Chara intermedia*, *Nitella opaca* and *Elodea Canadensis*; degree of surface cover of macrophytes 20 – 25% at the beginning of each study.
Chaoborus crystallinus was the only *Chaoborus* species present in the test systems. The test systems were described as oligo-mesotrophic. Dilution water: natural water collected from nearby water bodies

Test design: Physico-chemical analysis (dissolved oxygen, conductivity, pH and temperature), *Chaoborus* sampling and sampling of other zooplankton species was usually conducted weekly.

Chaoborus sampling: aquatic stages of *Chaoborus* were collected by two different sampling methods: a) macroinvertebrate artificial substrate sampler and b) net sampling; individuals were identified and counted alive, then released back into the corresponding enclosure. Classification in the different larval stages was done based on body length (Instar I/II < 0.5 cm, Instar III 0.5 - 1 cm and Instar IV > 1 cm).

a) Macroinvertebrate artificial substrate sampler (MASS): artificial substrates consisted of pebble baskets (volume ca. 10 L, pebbles 24/32 mm), plant stems (*Phragmitis communis*) and five horizontal hardboard plates (multiplates, 10 x 10 x 0.4 cm). On each sampling occasion, one artificial substrate sampler was retrieved from each enclosure using a net (mesh size: 250 µm) in order to prevent organisms from escaping.

b) Net sampling: a scoop net (area of the opening: 425 cm^2, mesh size: 250 µm) was used to collect *Chaoborus* specimens.

Other zooplankton species sampling: two depth-integrated water samples (ca. 3 L each) were taken, combined, sieved (mesh size: 63 µm) and preserved with 4% formaldehyde. Specimens were identified and counted using a stereo-microscope at 40 x magnification. Organisms were grouped as Ostracoda, soft-bodied rotifers, rotifers with shell or spines, Cyclopidae, Diaptomidae, Nauplia, small Cladocerans (< 1.4 mm) and large Cladocerans (> 1.4 mm).

Endpoints: Composition of *Chaoborus* populations (presence and dominance of different aquatic life stages); number of *Chaoborus* generations per year; inter-replicate and temporal variability of *Chaoborus* populations; influence of *Chaoborus* on the zooplankton community structure.

Test concentrations: Not relevant, only data from untreated enclosures was used

Test conditions: All studies were conducted at Gruenschwaige Research Station, located approximately 15 km from Freising, Bavaria, Germany. The surrounding area was used by the TU Munich for agricultural research projects, in which no plant protection products or other chemicals were applied.

Analytics: Not relevant.

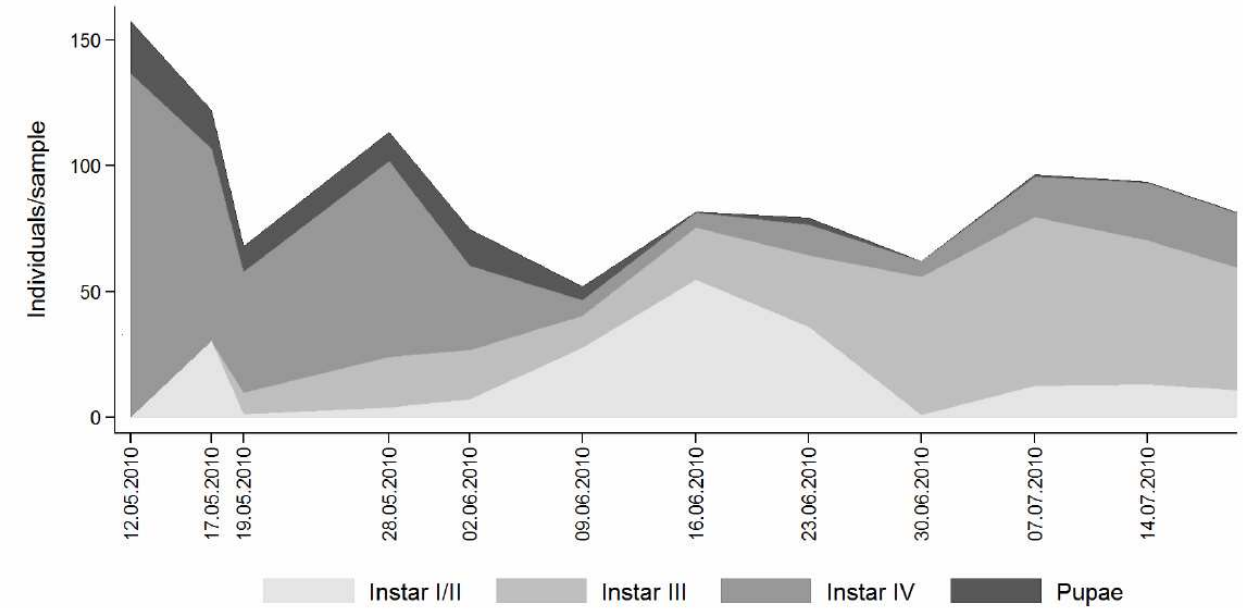
Statistics: Descriptive statistics; calculations of Minimum Detectable Differences (MDDs); multivariate statistical methods (partial Redundancy Analyses (RDAs) and Ordination analysis).

II. RESULTS AND DISCUSSION

Presence and dominance of the aquatic stages

The composition of the *Chaoborus* populations in the untreated enclosures analyzed in the present study varied significantly between the years. Due to its life cycle, the variation in the *Chaoborus* population structure between the seasons (i.e. within a year) was even higher than between years. A typical development of a *Chaoborus* population itemized into the different aquatic life stages is illustrated for the time period from mid-May to mid-July in Figure 8.2.8-1. Instar IV larvae dominated in May, instar III larvae in July and the proportion of instar I/II was highest in June.

Figure 8.2.8-1: Example of a typical development of a *Chaoborus* population in a mesocosm from mid-May to mid-July (data from 2010).



Number of generations per year

The recovery time of populations affected by the test item is an important aspect in using aquatic mesocosm study results for risk assessment. The generation time, reproductive rate and the number of generations per year are among the key factors for the recovery process of populations. It was shown for the studied test system in the south of Germany in Central Europe that there usually were three *Chaoborus* generations per year (from the end of April to the beginning of August), each lasting four to six weeks.

Inter-replicate variability
Inter-replicate variability was predominantly caused by natural variability between parallel enclosures and to a lesser extent by sampling errors. Calculations of Minimum Detectable Differences (MDDs) showed that the inter-replicate variability was sufficient low in order to reveal population relevant effects of chemicals on *Chaoborus* in mesocosm studies that follow common principles of design and evaluation. In addition, it was demonstrated, that effects on *Chaoborus* populations can be measured with high sensitivity using mesocosm test systems. Hence, population relevant effects of chemicals on *Chaoborus* will be picked up in mesocosm studies that follow common principles of design and evaluation.

Temporal variability
The population structure of *Chaoborus* varied significantly between the years and between the seasons (within a year). As indicated by partial Redundancy Analyses (RDAs) the study year could explain 10.8% of the total variance in the *Chaoborus* data set, whereas 23.3% could be explained by the variability within a year.

Influence on the zooplankton community structure
Ordination analysis revealed that *Chaoborus* larvae seem to promote high densities of rotifers and reduce the abundance of small crustaceans (nauplii larvae, copepods and small cladocerans). *Chaoborus* larvae prefer small crustaceans as a food source over rotifers (Kajak and Rybak 1979). Probably, as a consequence of the decrease in crustacean populations caused by *Chaoborus*, the numbers of rotifers increased due to the reduced predator pressure and lower food competition.

In the meantime, this report has been published in the peer-reviewed literature as: Janz P., Weltje L., Ebke K.P., Dawo U. 2015. Temporal population dynamics of the phantom midge *Chaoborus crystallinus* and its influence on the zooplankton community. Hydrobiologia 770(1): 273–287.

III. CONCLUSION

Analysis of the raw data of 19 mesocosm studies showed that the composition of *Chaoborus* populations varied significantly between the years with the variation in the *Chaoborus* population structure between the seasons (*i.e.* within a year) being higher than between years. The present study confirmed that population relevant effects of chemicals on *Chaoborus* will be picked up in mesocosm studies that follow common principles of design and evaluation. Furthermore, the study revealed that *Chaoborus* larvae seem to promote high densities of rotifers and reduce the abundance of small crustaceans.

From the performed literature search the following peer-reviewed scientific study investigating the aquatic toxicity of alpha-cypermethrin to the moorfrog *Rana arvalis* was considered for the aquatic risk assessment of alpha-cypermethrin. Due to missing analytical measurements in this study and the insufficient description of the testing method, exposure duration, etc. it was classified as "not reliable" (RI 3). For details please see the literature search and evaluation files also provided within the submission for Annex I Renewal. Nevertheless, the study is considered to provide some additional information on chronic effects on amphibians (note that a reliable, RI 2, study on acute effects is available – see below). The data have not been used or evaluated during the previous Annex I inclusion process and thus, relevant information and results of the study are described in the following summary.

Report:	CA 8.2.8/6 Greulich K. Pflugmacher S., 2003a Differences in susceptibility of various life stages of amphibians to pesticide exposure 2003/1034399
Guidelines:	none
GLP:	no

Executive Summary

The influence of alpha-cypermethrin on hatching success, mortality, duration of metamorphosis, and growth of moor frog (*Rana arvalis*) tadpoles exposed at various life stages was investigated under worst-case laboratory conditions. Preliminary tests used small clutches of eggs (approximately 10 embryos at stage 10–12) and 10 tadpoles (stage 20) and exposed them for 48 hours to nominal alpha-cypermethrin concentrations of 0.1, 1.0 and 10.0 µg a.s./L in three replicates per treatment. Due to overt toxicity in the 10 µg/L treatment the definitive test was conducted with 0.1 and 1.0 µg/L (the larvae/eggs exposed to 1.0 µg/L also showed some effects). In the study of the life-stage treatment 10 individuals were exposed to nominal alpha-cypermethrin concentrations of 0.1 and 1.0 µg a.s./L. The tadpoles were examined for the mortality and behavioral abnormalities. All experiments were replicated three times. In addition, a water control and a solvent control were set up for all experiments. Body weight and snout-vent length of test organisms were assessed at the end of the experiment, when resorption of the tail was completed. The preliminary test showed overt toxicity in the 10 µg/L treatment and the larvae/eggs exposed to 1.0 µg/L also showed some effects (e.g. impact on hatching rate). However, there was no clear picture concerning growth, where sometimes the treated animals were bigger and sometimes smaller, depending on the exposed life-stage. The definitive test over about 60 days (test duration not clearly indicated in the paper) was conducted with treatments 0.1 and 1.0 µg/L. Growth was assessed by an unconventional method (linear regression of length vs. weight and then comparing slopes with Fisher's exact test). The slope of the 0.1 µg/L treatment was comparable to the control, while the 1.0 µg/L slope showed a significant difference. Further, there was no difference in duration of metamorphosis at 0.1 µg/L. Thus, the 0.1 µg/L treatment may be regarded as a preliminary NOEC.

In the present study, moor frog (*Rana arvalis*) tadpole chronic toxicity of alpha-cypermethrin was investigated. After ca. 60-d exposure to 0.1 µg/L no significant differences compared to the control were found for length, weight and duration of metamorphosis.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg. No. 4 078 193); purity: >99%; purchased from Fluka (Seelze, Germany).

B. STUDY DESIGN

Test species: Moor frog (*Rana arvalis*); eggs (stage 10 - 12) and tadpoles (stage 20 according to Gosner, 1960), two egg clutches were collected from a wetland pond in northeastern Germany in April 2002; one egg clutch used for hatching studies immediately after collection, the other one was reared until tadpoles reached specific developmental stages and then used for studies.

Test design: Preliminary and definitive study: small egg clutches (approx. 10 embryos at stage 10-12) or tadpoles (10 individuals) were exposed to a water control, a solvent control and alpha-cypermethrin treatments. The control and test substance treatments were replicated 3 times respectively.

Preliminary study: Egg clutches and tadpoles were exposed over 48 hours.

Definitive study: Exposure over the whole developmental stage: egg stage, embryo stage and tadpole stage until metamorphosis (resorption of tail completed).

During the experiments animals were observed for mortality and behavioral abnormalities. Body weight and snout-vent length of test organisms were assessed at the end of the experiment, when resorption of the tail was completed.

Endpoints: Hatching success, mortality and sublethal effects (duration of metamorphosis, body weight and length).

Test rates: Water control (artificial, demineralized well water); solvent control (acetonitrile: 100 µL/L); 0.1, 1 and 10 µg alpha-cypermethrin/L in the preliminary studies and 0.1 and 1 µg a.s./L in the definitive study.

Test conditions: Test tanks containing 10 L artificially salted, demineralized water; water temperature: 20°C; light : dark cycle: 14:10 hours; feeding every third day: powdered dry food (Tetramin AZ 40).

Analytics: No analytical measurements conducted.

Statistics: Descriptive statistics; one-way ANOVA followed by Newman-Keuls test ($p < 0.05$) for hatching success data; Fisher`s exact test ($p < 0.05$) for mortality data; regression analysis and Fisher's exact test ($p < 0.05$) for body length and weight data.

II. RESULTS AND DISCUSSION

Analytical results:
Analytical measurements of test item concentrations were not conducted.

Biological results:
The influence of alpha-cypermethrin on hatching success, mortality, duration of metamorphosis, and growth of moor frog (*Rana arvalis*) tadpoles exposed at various life stages was investigated under worst-case laboratory conditions. Preliminary tests used small clutches of eggs (approximately 10 embryos at stage 10–12) and 10 tadpoles (stage 20) and exposed them for 48 hours to nominal alpha-cypermethrin concentrations of 0.1, 1.0 and 10.0 µg a.s./L in three replicates per treatment. Due to overt toxicity in the 10 µg/L treatment the definitive test was conducted with 0.1 and 1.0 µg/L (the larvae/eggs exposed to 1.0 µg/L also showed some effects). In the study of the life-stage treatment 10 individuals were exposed to nominal alpha-cypermethrin concentrations of 0.1 and 1.0 µg a.s./L. The tadpoles were examined for the mortality and behavioral abnormalities. All experiments were replicated three times. In addition, a water control and a solvent control were set up for all experiments. Body weight and snout-vent length of test organisms were assessed at the end of the experiment, when resorption of the tail was completed. The preliminary test showed overt toxicity in the 10 µg/L treatment and the larvae/eggs exposed to 1.0 µg/L also showed some effects (e.g. impact on hatching rate). However, there was no clear picture concerning growth, where sometimes the treated animals were bigger and sometimes smaller, depending on the exposed life-stage. The definitive test over about 60 days (test duration not clearly indicated in the paper) was conducted with treatments 0.1 and 1.0 µg/L. Growth was assessed by an unconventional method (linear regression of length vs. weight and then comparing slopes with Fisher's exact test). The slope of the 0.1 µg/L treatment was comparable to the control, while the 1.0 µg/L slope showed a significant difference. Further, there was no difference in duration of metamorphosis at 0.1 µg/L. Thus, the 0.1 µg/L treatment may be regarded as a preliminary NOEC.

III. CONCLUSION

In the present study, moor frog (*Rana arvalis*) tadpole chronic toxicity of alpha-cypermethrin was investigated. After ca. 60-d exposure to 0.1 µg/L no significant differences compared to the control were found for length, weight and duration of metamorphosis.

From the performed literature search the following peer-reviewed scientific study investigating lethal and sublethal effects of alpha-cypermethrin (and two other insecticides) on two developmental stages of *Xenopus laevis* was considered relevant and reliable (with restrictions, RI 2) for the aquatic risk assessment of alpha-cypermethrin (for details please see the literature search and evaluation files also provided within the submission for Annex I Renewal). The data had not been used or evaluated during the previous Annex I inclusion process and thus, relevant information and the results for alpha-cypermethrin of this study are described in the following summary.

Report:	CA 8.2.8/7 Yu S. et al., 2013a Lethal and sublethal effects of three insectidides on two developmental stages of Xenopus laevis and comparison with other amphibians 2013/1417940
Guidelines:	none
GLP:	no

Executive Summary

Lethal and sublethal effects of alpha-cypermethrin on African clawed frog (*Xenopus laevis*) embryos and larvae were investigated over a period of 96 h under semi-static test conditions. Embryos were exposed to alpha-cypermethrin at nominal concentrations of 10, 20, 40, 80, 160 µg alpha-cypermethrin/L (corresponding to measured concentrations of 4.5, 13.5, 34.4, 77.1 and 160.7 µg a.s./L) in 5 replicates per treatment containing 20 embryos each. Frog larvae were exposed at nominal concentrations of 1.25, 2.5, 5, 10 and 20 µg a.s./L (corresponding to measured concentrations of 1.0, 2.0, 4.5, 8.5 and 22.4 µg a.s./L) in 5 replicates per treatment containing 10 larvae each. In addition, a solvent control was set up for embryo and larvae tests. Embryos and larvae were observed for mortality and sub-lethal effects daily. Body length of larvae was assessed at the end of the experiment. Furthermore, data were used to compare toxicity of *X. laevis* with that of other amphibians.

The biological results are based on measured concentrations. Alpha-cypermethrin caused mortality, malformations, and growth inhibition in both developmental stages at all tested concentrations. Gut abnormalities, axial/tail malformations, and edema were the 3 major malformations observed. Compared with embryos, larvae were more sensitive to alpha-cypermethrin. The results suggest that *X. laevis* larvae may generate more protective toxicity estimates in risk assessments than embryos. Furthermore, it was shown that *Xenopus laevis* may provide useful toxicity thresholds for pyrethroid insecticides.

In a semi-static acute toxicity study with *Xenopus laevis* embryos and larvae the LC_{50} (96 h) values were determined to be 30.6 and 6.9 µg alpha-cypermethrin/L, respectively (based on measured concentrations).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (BAS 310 I, Reg.No. 4 078 193); purity: 99.5%; purchased from ChemService.

B. STUDY DESIGN

Test species: African clawed frog (*Xenopus laevis*); embryos (Nieuwkoop and Faber (NF) stage 8 - 11) and larvae (NF stage 46); derived from laboratory-bred *X. laevis.*

Test design: Experiments were conducted according to the Frog Embryo Teratogenesis Assay-Xenopus (FETAX) protocol (ASTM International, 2004) with modifications. Both experiments were conducted in a semi-static test system with daily renewal of test solutions over an exposure period of 96 hours. Five replicates were set up for each of the five test item concentrations and for the solvent control (acetone) in both experiments.

Embryonic experiment: Embryos were examined with a microscope for viability and developmental stages. Twenty viable embryos from 3 clutches (NF stage 8 -11) were mixed and randomly assigned to each beaker.

Larval experiment: NF stage 46 larvae from 3 clutches were mixed and randomly placed in beakers (10 larvae/beaker).

Embryos and larvae were checked daily for mortality. At the end of the 96 h exposure, surviving larvae were euthanized preserved in 10% formalin and each individual was examined for abnormalities with a microscope. Body length of test organisms was assessed at the end of the experiment. Water quality was measured every other day before water change.

Endpoints: Median lethal concentrations (LC_{50}); median teratogenic concentrations (TC_{50}); teratogenic index (TI); sub-lethal effects (abnormal behavior, body length).

Test rates: Embryonic experiment: Solvent control, 10, 20, 40, 80, 160 µg alpha-cypermethrin/L (nominal) corresponding to measured concentrations of 0, 4.5, 13.5, 34.4, 77.1 and 160.7 µg alpha-cypermethrin/L.

Larval experiment: Solvent control, 1.25, 2.5, 5, 10 and 20 µg alpha-cypermethrin/L (nominal) corresponding to measured concentrations of 0, 1.0, 2.0, 4.5, 8.5 and 22.4 µg alpha-cypermethrin/L.

Test conditions: 50 mL beakers containing 40 mL FETAX solution for the embryonic experiments and 1 L beakers containing 1 L FETAX solution for the larval experiments; temperature: 22 - 24° C; dissolved oxygen: 5.07 - 8.59 mg/L; conductivity: 1610 - 1879 µS/cm; pH: 6.5 - 8.0; average ammonia concentration: 0.36 mg/L (0.04 - 1.32 mg/L); feeding: larvae were given a diet comprised of Nasco frog brittle, Trout Growers Ration, and Nutrafin Max tropical fish food approx. 1 h before water changes.

Analytics: Analytical verification of test item concentrations was conducted using an Agilent 6890 series gas chromatograph equipped with an electron capture detector.

Statistics: Descriptive statistics; LC_{50s} and TC_{50s} were determined using a logistic model in JMP 9.0.0 (SAS Institute); TI was calculated as the ratio LC_{50}/ TC_{50}. Incidence of malformations was compared using the Kruskal–Wallis test. If a statistical significance was indicated, a nonparametric multiple comparison with control was performed. Difference in total length was compared using one-way ANOVA or Welch's test. Pesticide-treated groups were further compared with controls using Dunnett's test. Results were considered significant at $\alpha = 0.05$.

II. RESULTS AND DISCUSSION

Analytical measurements: Analytical verification of test item concentrations was conducted in each test item treatment. Measured concentrations of alpha-cypermethrin in the 10 µg/L and 20 µg/L treatments in the embryonic test were 4.5 µg/L and 13.5 µg/L (corresponding to 45% and 67.5% of nominal concentrations), respectively. This may be due to the absorption of the chemical to glass. However, recovery in the higher concentrations ranged from 86% to 100% of the nominal concentrations. In the larval experiment, the actual concentrations of alpha-cypermethrin ranged from 80% to 112% of the nominal concentrations. The biological results are based on measured concentrations.

Biological results: Mortality rates of 4% and 2% were observed in the solvent controls of the embryonic and larval experiments, respectively. After exposure of embryos over 96 hours, 12%, 38% and 44% mortality was observed at measured concentrations of 4.5, 13.5 and 34.4 µg a.s./L, respectively. In the two highest tested concentrations of 77.1 and 160.7 µg a.s./L all embryos were dead at test end. Larval mortality increased from 16% in the lowest measured concentration of 1.0 µg a.s./L to 88% in the highest concentration of 22.4 µg a.s./L after 96 hours of exposure.
In the embryonic experiments, abnormal behaviors such as twitching and convulsion occurred and were more obvious when embryos were occasionally disturbed during water change. In the larval experiments, alpha-cypermethrin induced abnormal behaviors such as hypersensitivity, twitching, convolution, and swimming in a circle at all tested concentrations. Furthermore, alpha-cypermethrin induced malformations in both embryos and larvae in all concentrations. Gut abnormalities, axial/tail malformations, and edema were the 3 major malformations observed. In both experiments, incidence of total malformations was significantly different among alpha-cypermethrin treatments (Kruskal-Wallis test, $p < 0.05$) and all concentrations caused significantly higher incidence of total malformations compared with controls (non-parametric comparison, $p < 0.05$). The embryonic TC_{50} was determined to be 4.4 µg a.s./L and the TI was calculated to be 6.95 (strong teratogen).
All concentrations of alpha-cypermethrin produced significantly smaller larvae than controls (Dunnett's test, $p < 0.05$).
Comparison of toxicity data for *X. laevis* and data for other amphibians indicate that *Xenopus laevis* larvae had high sensitivity to alpha-cypermethrin/cypermethrin relative to other larval amphibians. The results suggest that *X. laevis* larvae may generate more protective toxicity estimates in risk assessments than embryos. Furthermore, it was shown that *Xenopus laevis* may provide useful toxicity thresholds for pyrethroid insecticides.

The mortality rates and resulting endpoints of both experiments are summarized in Table 8.2.8-3 (embryonic experiment) and Table 8.2.8-4 (larval experiment).

Table 8.2.8-3: Lethal effects of alpha-cypermethrin on African clawed frog (*Xenopus laevis*) embryos after exposure over 96 hours

III. CONCLUSION

In a semi-static acute toxicity study with *Xenopus laevis* embryos and larvae the LC_{50} (96 h) values were determined to be 30.6 and 6.9 µg alpha-cypermethrin/L, respectively (based on measured concentrations).

From the performed literature search the following peer-reviewed scientific study investigating the efficacy and environmental fate of alpha-cypermethrin applied to rice fields for the control of chironomid midge larvae was considered relevant and reliable (with restrictions, RI 2) for the aquatic risk assessment of alpha-cypermethrin (for details please see the literature search and evaluation files also provided within the submission for Annex I Renewal). The data had not been used or evaluated during the previous Annex I inclusion process and thus, relevant information and results of this study are described in the following summary.

Report: CA 8.2.8/8
Helliwell S.,Stevens M.M., 2000a
Efficacy and environmental fate of Alpha-Cypermethrin applied to rice fields for the control of chironomid midge larvae (Diptera: Chironomidae)
2000/1024088
Guidelines: none
GLP: no

Executive Summary

The pyrethroid insecticide alpha-cypermethrin was evaluated for the control of chironomid midge larvae in two field trials in New South Wales during 1997 - 1998 (trial 1) and 1998 - ± 1999 (trial 2) rice seasons. In each trial, two bays were designated as untreated controls, two were treated with a chlorpyrifos as a toxicant control and six bays (two at each of three application rates) were treated with alpha-cypermethrin. In trial 1, alpha-cypermethrin was applied at 10, 20, and 30 g a.s./ha, while in trial 2, application rates of 6, 10, and 20 g a.s./ha were evaluated. All treatments were applied 6 days after flooding using a single nozzle hand sprayer. In trial 1, three samples were taken from each bay 4, 9, 14, 19, and 24 days after application (DAA), whilst in trial 2, four samples were taken from each bay 4, 9, 14, 19, and 24 DAA. Concentrations of alpha-cypermethrin in the water column were monitored during each trial.

In trial 1 (1997 – 1998), alpha-cypermethrin applied at 10, 20, and 30 g a.s./ha provided between 54% and 73% control of target Chironominae in the first 19 DAA. Populations of Chironominae were very low during trial 1 with estimated control density at 14 DAA of approximately 485 larvae/m². Alpha-cypermethrin strongly suppressed the non-target group, but also provided significant reductions in target Chironominae at 9 DAA (all rates) and at 14 DAA (10 g a.s./ha rate only). In trial 2 (1998 - 1999), target Chironominae, were far more abundant with an estimated control density 14 DAA of approximately 13100 larvae/m². Alpha-cypermethrin provided > 99% control of Chironominae for 19 DAA at all rates evaluated (6, 10 and 20 g a.s./ha). In trial 2, all treatments significantly reduced populations of target Chironominae at each sampling period up to and including 19 DAA. At test end no statistically significant reductions in larval chironomid populations (including both target Chironominae and 'other Chironomidae') were observed in the 10 and 20 g a.s./ha treatments in trial 1 and the 6 and 10 g a.s./ha treatments in trial 2 when compared to the control populations. Hence, a recovery potential of both target Chironominae and other Chironomidae populations could be observed in the course of both trials after exposure to several alpha-cypermethrin concentrations. NOEAEC values were estimated based on initial (DAT 1) measured water concentrations of alpha-cypermethrin (these endpoints were not reported in the publication).

In two rice field trials, the recovery of chironomid populations was observed following exposure to alpha-cypermethrin at 10 and 20 g a.s./ha over an exposure period of 29 days (trial 1) and at 6 and 10 g a.s./ha over 24 days (trial 2). Based on the effects of alpha-cypermethrin on abundances of chironomid midge larvae and initial (DAT 1) measured water concentrations in the 6 and 10 g a.s./ha treatments, a NOEAEC value of about 0.16 - 0.23 µg a.s./L was derived.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (tested with Dominex® 100 EC, content of a.s.: 100 g alpha-cypermethrin/L); purchased from FMC International AG.

B. STUDY DESIGN

Test species: Naturally-occurring non-biting midges of different taxa; Chironominae (target; predominantly *Chironomus tepperi* Skuse) and 'other chironomids' (predominantly Tanypodinae).

Test site: The test site (size approximately 300 m²) was located at Yanco Agricultural Institute in southwestern New South Wales, Australia. Alternate bays in rows were used as treatment bays, with intervening bays being used as buffer zones. Two rows of nine rectangular bays with earthen banks (each approximately 30 m^2) were used in each trial. The two trials were conducted on adjacent sites on a Birganbigil clay loam soil.

Test design: Field studies conducting during 1997-1998 (trial 1) and 1998-1999 (trial 2). In each trial, two bays were designated as untreated controls, two were treated with a standard chlorpyrifos treatment and six bays (two at each of three application rates) were treated with alpha-cypermethrin. All chemical treatments were applied to the water surface in approximately 5 L of water using a single nozzle hand sprayer. All treatments were applied 6 days after flooding. All treatment and control bays were sown with pregerminated rice (cv. `Namaga', 120 kg dry weight/ha) by hand broadcasting within 2 h of chemical treatments being applied.
Soil core sampling combined with magnesium sulphate flotation was used to quantify larval chironomid populations by using plastic cylinder (96 mm Ø). In trial 1, three samples were taken from each bay 4, 9, 14, 19, 24 and 29 DAA, whilst in trial 2 four samples were taken from each bay 4, 9, 14, 19 and 24 DAA. Extracted larvae were divided into two groups, Chironominae and 'other chironomids' (predominantly Tanypodinae).
Single 1 L composite water samples were taken from the control and alpha-cypermethrin treated bays with five subsamples from random points in each bay. In trial 1, samples were collected at 1, 2, 5, 9, 14, 19 and 25 DAA. In trial 2, samples were collected at 1, 2, 3, 4, 7, 10, 14 and 18 DAA.

Endpoints: NOEAEC, based effects on larval chironomid abundance.

Test concentrations:	Control Treatments (both trials): untreated control, toxicant control (chlorpyrifos, tested as Lorsban® 500 EC (DowElanco, Australia), at 500 g a.s./L applied at 75 g a.s./ha) Alpha-cypermethrin treatment (trial 1): 10, 20 and 30 g a.s./ha Alpha-cypermethrin treatment (trial 2): 6, 10 and 20 g a.s./ha.
Test conditions:	Two rows of nine rectangular bays with earthen banks (each approximately 30 m²; Birganbigil clay loam soil) were used in each trial. Each bay was supplied with water from a central channel. A water depth of approximately 12 cm was maintained in the bays throughout both trials. rice: cv. `Namaga', 120 kg dry weight/ha; mean values of environmental parameters: pH: 9.1; conductivity: 90.2 µS/cm; water temperature: 23.8 °C; rainfall: 0.9 mm (trial 1, first 25 DAA); pH: 7.7; conductivity: 172.3 µS/cm; water temperature: 19.0 °C; rainfall: 1.0 mm (trial 2, first 18 DAA).
Analytics:	Analytical verification of test item concentrations in water was conducted using a Hewlett Packard 5890 Series II gas chromatograph equipped with an electron capture detector.
Statistics:	Descriptive statistics, Data were transformed to $y' = \log_e (y+1)$ and analyzed using ANOVA and Tukey's HSD test ($p < 0.05$). NOEAEC values were estimated based on measured concentrations of alpha-cypermethrin in water (endpoints are not reported in publication).

II. RESULTS AND DISCUSSION

Analytical measurements: Concentrations of alpha-cypermethrin in the water column were monitored during each trial. In both trials, alpha-cypermethrin levels in the water column followed an exponential decay, levels declining to < 0.015 µg/L at 5 DAA for trial 1 and at 7 DAA for trial 2. Concentrations in water for the 20 g a.s./ha rate ranged from 0.23 to 0.41 mg/L 1 DAA down to 0.008 mg/L at 18 DAA, whilst at the 6 g a.s./ha rate alpha-cypermethrin concentrations declined to below the detection limit (0.001 mg/L) at 18 DAA.

Biological results: In trial 1 (1997 – 1998), alpha-cypermethrin applied at 10, 20, and 30 g a.s./ha provided between 54% and 73% control of target Chironominae in the first 19 DAA. Populations of Chironominae were very low during trial 1 with estimated control density 14 DAA of approximately 485 larvae/m². Alpha-cypermethrin strongly suppressed the non-target group, but also provided significant (Tukey's HSD test; $p < 0.05$) reductions in target Chironominae at 9 DAA (all rates) and at 14 DAA (10 g a.s./ha rate only).
In trial 2 (1998 - 1999), target Chironominae, were far more abundant with an estimated control density 14 DAA of approximately 13100 larvae/m². Alpha-cypermethrin provided > 99% control of Chironominae for 19 DAA at all rates evaluated (6, 10 and 20 g a.s./ha). In trial 2, all treatments significantly ($p < 0.05$) reduced populations of target Chironominae at each sampling period up to and including 19 DAA.

At test end no statistically significant reductions in larval chironomid populations (including both target Chironominae and 'other Chironomidae') were observed in the 10 and 20 g a.s./ha treatments in trial 1 and the 6 and 10 g a.s./ha treatments in trial 2 when compared to the control populations. Hence, a recovery potential of both target Chironominae and other Chironomidae populations could be observed in the course of both trials after exposure to several alpha-cypermethrin concentrations. Initial (DAT 1) measured water concentrations were taken from the graphs in the paper. NOEAEC values were based on initial (DAT 1) measured water concentrations of alpha-cypermethrin in the 6 and 10 g a.s./ha treatments (these endpoints were not reported in the publication).

III. CONCLUSION

In two rice field trials, the recovery of chironomid populations was observed following exposure to alpha-cypermethrin at 10 and 20 g a.s./ha over an exposure period of 29 days (trial 1) and at 6 and 10 g a.s./ha over 24 days (trial 2). Based on the effects of alpha-cypermethrin on abundances of chironomid midge larvae and initial (DAT 1) measured water concentrations in the 6 and 10 g a.s./ha treatments, a NOEAEC value of about 0.16 - 0.23 µg a.s./L was derived.

From the performed literature search the following peer-reviewed scientific study investigating the uptake, translocation, and metabolism of the metabolite 3-phenoxybenzoic acid (3-PBA) in the submerged rooted macrophyte water milfoil (*Myriophyllum elatinoides*) was considered relevant and reliable (with restrictions, RI 2) for the aquatic risk assessment of alpha-cypermethrin (for details please see the literature search and evaluation files also provided within the submission for Annex I Renewal). The data had not been used or evaluated during the previous Annex I inclusion process and thus, relevant information and results of this study are described in the following summary.

Report: CA 8.2.8/9
Ando D. et al., 2012a
Uptake, translocation, and metabollism of 3-phenoxybenzioc acid in the submerged rooted macrophyte water milfoil (Myriophyllum elatinoides)
2012/1367684
Guidelines: none
GLP: no

Executive Summary

In a 14-day static toxicity laboratory study, the toxicity and the metabolic pathway of 3-phenoxybenzoic acid (3-PBA; metabolite of alpha-cypermethrin) in water milfoil *Myriophyllum elatinoides* was investigated. Water milfoils were exposed to a water control and to ^{14}C-radiolabeled 3-PBA at an exposure concentration of 3.28 ppm (equivalent to 3280 µg/L; concentration in overlying water or in sediment pore water). Exposure was conducted in a medium-containing shoot/leaves chamber *via* water treatment and in a sediment-containing roots chamber *via* sediment treatment. Plant sampling for ^{14}C-distribution analysis and determination of plant growth (total length and wet weight) was conducted 0.5, 1, 3, 5, 7 and 14 days after test initiation.

No growth inhibition of the plants was confirmed in the sequestered glass chambers after comparing the length (ranging from 1.1 to 1.8 cm) and fresh weight (ranging from 0.7 to 0.11 g) with those grown in the acclimation aquarium during a 14-day incubation period.
The uptake of ^{14}C-radiolabeled 3-PBA dissolved in water by the shoot/leaves amounted to 15.85% of the applied radioactivity (AR) after 0.5 days, and ^{14}C translocation to the roots was minimal during 14 days. Slower uptake of the radioactivity from test item treated sediment by the roots was observed (6.37%AR after 14 days) and 1.71%AR was trans-located to the shoot/leaves. Oxidation, reduction and conjugation of the test item proceeded in the macrophyte.

Water and sediment exposure of the submerged rooted macrophyte *Myriophyllum elatinoides* to 3-phenoxybenzoic acid (3-PBA, metabolite of alpha-cypermethrin) at a concentration of 3.28 ppm caused no growth inhibition after incubation over 14-days. Thus, the NOEC based on growth inhibition can be estimated to be ≥ 3.28 ppm (equivalent to ≥ 3280 µg/L; concentration in overlying water or in sediment pore water).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: 3-phenoxybenzoic acid (3-PBA; metabolite of alpha-cypermethrin); uniformly labeled with ^{14}C at the phenoxyphenyl ring (specific radioactivity: 4.37 GBq/mmol); analytical grade; synthesized in-house.

B. STUDY DESIGN

Test species:	Water milfoil (*Myriophyllum elatinoides* Gaudich), Haloragaceae, a dicotyledonous, submerged rooted macrophyte; purchased from Aqua Rise Co., Osaka, Japan; cultivated in-house for at least 10 days.
Test design:	Static system; 14 day incubation; 3 day rooting phase. 1 test item concentration; each exposure (water and sediment treatments) was conducted in triplicate. Exposure experiments were conducted using a glass vessel partitioned with a welded grass board that included shoot/leaves and roots chambers. The chambers were individually filled with 120 mL of the AAP medium (shoot/leaves chamber) and 35 g of OECD sediment moistened with 20 mL of AAP medium (roots chamber). The test solution was applied to the AAP medium in the shoot/leaves chamber via water treatment or to the sediment in the roots chamber via sediment treatment followed by uniform mixing to establish an exposure concentration of 3.28 ppm (0.167 MBq). The root tip of the sterilized plant (length: 16.5 - 18.3 cm; fresh body weight: 0.34 -0.51 g) was buried into the sediment and the shoot/leaves portion was immersed in the AAP-medium. Sampling was conducted at 0.5, 1, 3, 5, 7 and 14 days after treatment.
Endpoints:	NOEC based on growth inhibition (based on length and fresh weight); uptake rates; metabolite distribution.
Test concentrations:	0 (water control), 3.28 µg ^{14}C-labeled 3-PBA/L (0.167 MBq); equivalent to 3280 µg/L (concentration in overlying water or in sediment pore water).
Test conditions:	Partitioned glass vessel, including a sediment containing root chamber and a medium containing shoot/leaves chamber; root chamber was filled with 35 g artificial sediment (OECD 218) moistened with 20 mL AAP medium; shoot/leaves chamber was filled with 120 mL AAP (American Academy of Pediatrics) water medium; pH of AAP medium: 7.0 ± 0.5; temperature: 20 ± 2 °C; photoperiod: 16 h light : 8 h dark, light intensity: 120 µE*m-^{2}s-^{1}[10].
Analytics:	A reversed-phase HPLC system with scintillation counting was used to analyzed 3-PBA and its degradation products. One-dimesional NMR spectra was measured using a Spectrometer. Liquid chromatography-electrospray ionization-mass spectrometry (LC-ESI-MS) analysis was conducted to measure radioactivity in water, sediment extract, and rinsate/extract of the plants.
Statistics:	No statistical methods were described.

II. RESULTS AND DISCUSSION

Metabolic distribution: Radioactivity in water, sediment and plants was measured 0.5, 1, 3, 5, 7 and 14 days after test initiation. The total recovery of ^{14}C in each treatment was greater than 95% of the applied radioactivity throughout the test period, indicating the insignificant loss of ^{14}C by volatilization or adsorption to the test vessel. In case of the sediment treatment, approximately 80%AR remained as unaltered 3-PBA in the roots chamber, most of which originated from ^{14}C in the interstitial medium water of the sediment. Regarding the water treatment, approximately 80%AR remained in the medium, and no ^{14}C was detected in the sediment phase. The uptake of ^{14}C-radiolabeled 3-PBA dissolved in water by the shoot/leaves amounted to 15.85% of the applied radioactivity (AR) after 0.5 days, and ^{14}C translocation to the roots was minimal during 14 days. Slower uptake of the radioactivity from test item treated sediment by the roots was observed (6.37%AR after 14 days) and 1.71%AR was trans-located to the shoot/leaves. Oxidation, reduction and conjugation of the test item proceeded in the macrophyte.

Plant growth observations: No growth inhibition of the plants was confirmed in the sequestered glass chambers after comparing the length (ranging from 1.1 to 1.8 cm) and fresh weight (ranging from 0.7 to 0.11 g) with those grown in the acclimation aquarium during a 14-day incubation period.

III. CONCLUSION

Water and sediment exposure of the submerged rooted macrophyte *Myriophyllum elatinoides* to 3-phenoxybenzoic acid (3-PBA, metabolite of alpha-cypermethrin) at a concentration of 3.28 ppm caused no growth inhibition after incubation over 14-days. Thus, the NOEC based on growth inhibition can be estimated to be ≥ 3.28 ppm (equivalent to ≥ 3280 µg/L; concentration in overlying water or in sediment pore water).

CA 8.3.1.1 Acute toxicity to bees

CA 8.3.1.1.1 Acute oral toxicity

Report: CA 8.3.1.1.1/1
Barth M., 2006a
Acute toxicity of BAS 310 I to the honeybee Apis mellifera L. under laboratory conditions
2005/1026137
Guidelines: OECD 213, OECD 214
GLP: yes
(certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

In a dose response test, young adult worker bees (*Apis mellifera* L.) were exposed to alpha-cypermethrin. The toxicity of the test product was determined in an oral test at concentrations of 0.800, 0.400, 0.200, 0.100 and 0.050 µg a.s./bee (0.650, 0.375, 0.192, 0.100 and 0.050 µg a.s./bee actual intake). Additionally, honeybees were treated with dimethoate as reference item at concentrations ranging from 0.0625 to 0.50 µg a.s./bee (0.499 to 0.0625 µg a.s./bee actual intake). Two control treatments consisting of sucrose solution alone and sucrose solution containing 1% ethyl acetate were carried out**.** The test was conducted with 3 replicates for the treatment groups; each of the test cages contained 10 bees. Assessment of mortality was done after 4, 24 and 48 hours. Additionally behavioral abnormalities were observed within 48 hours after oral exposure.

In the oral toxicity test (48 h) the average mortalities for the test item treatments of 0.800, 0.400, 0.200, 0.100 and 0.050 µg a.s./bee (0.650, 0.375, 0.192, 0.100 and 0.050 µg a.s./bee actual intake) were 100%, 66.75%, 16.7%, 13.3% and 10%, respectively. In the sucrose control and sucrose/ethyl acetate control, average mortalities were 3.3% and 0%, respectively.
At assessments conducted 4 hours after oral exposure of the test item effects on behavior were observed in honeybees consuming doses of 0.05 up to 0.650 µg a.s./bee. At the assessments conducted 24 hours after oral exposure of the test item bees had generally recovered. No different behavior for all surviving bees consuming doses up to 0.375 µg a.s./bee compared to control bees was observed.

The LD_{50} (48 h) was 0.246 µg alpha-cypermethrin (95% CL 0.201 – 0.301 µg alpha-cypermethrin) consumed a.s./bee.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: alpha-cypermethrin (BAS 310 I, Reg. no. 4 078 193); batch COD-000166 (99.3%, analyzed).

B. STUDY DESIGN

Test species: Honeybee (*Apis mellifera carnica* L.), worker bees from a healthy and queen-right colony, age: 4 - 6 weeks, source: Bienenfarm Kern GmbH, Leipzig, Germany, collected in the morning of use and kept under test conditions.

Test design: Oral (LD_{50} test): 48 h; 5 treatment groups; 3 replicates each consisting 10 bees. The mortality was assessed 4, 24 and 48 h after application.

Endpoints: LD_{50}, behavioral abnormalities.

Reference item: Perfekthion EC 400 (dimethoate 408.7 g/L analyzed).

Test concentrations: 0.800, 0.400, 0.200, 0.100 and 0.050 µg a.s./bee. Actual intake: 0.650, 0.375, 0.192, 0.100 and 0.050 µg a.s./bee.

Test conditions: Bees were kept in the dark at 24°C – 25°C (69 - 71% RH) in the oral test. Food: 50 % w/v sucrose solution.

Statistics: Fisher's Exact Binomial Test with Bonferroni Correction for mortality data, $\alpha \leq 0.05$. Probit analysis according to the maximum likelihood method (FINNEY 1971) for calculation of the LD_{50} with 95 % confidence intervals. Statistical program used: ToxRat Professional 2.09 (2004).

II. RESULTS AND DISCUSSION

In the oral toxicity test no statistically significant effects on survival (10.0, 13.3 and 16.7% mortality, respectively) were observed at consumed doses of 0.050, 0.100 and 0.192 µg a.s./bee during 48 hours (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha \leq 0.05$). For the consumed doses of 0.375 and 0.650 µg a.s./bee statistically significant effects of the test item on survival (66.7 and 100.0% mortality) were observed after 48 hours (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha \leq 0.05$). Therefore the LD_{50} (48 h) was calculated as 0.246 µg consumed a.s./bee in the oral toxicity test.

At assessments conducted 4 hours after oral exposure of the test item effects on behavior were observed in honeybees consuming doses of 0.05 up to 0.650 µg a.s./bee. At the assessments conducted 24 hours after oral exposure of the test item bees had generally recovered. No different behavior for all surviving bees consuming doses up to 0.375 µg a.s./bee compared to control bees was observed.

See results are summarized below Table 8.3.1.1.1-1.

Table 8.3.1.1.1-1: Toxicity of alpha-cypermethrin to honeybees (*Apis mellifera* L.) in an oral toxicity test

	Oral test (48 h)
	µg a.s./bee
LD_{50}	0.246
95 %-CL	0.201 - 0.301

III. CONCLUSION

The LD_{50} (48 h) was 0.246 µg alpha-cypermethrin (95 % CL 0.201 – 0.301 µg alpha cypermethrin) consumed a.s./bee.

Executive Summary

In a dose response test, young adult worker bumblebees (*Bombus terrestris* L.) were exposed to BAS 310 I. The acute toxicity of the test item was determined in an oral test at dose rates of 0.13, 0.25, 0.51, 1.01 and 2.02 µg BAS 310 I/bumblebee which is corresponding to 0.13, 0.25, 0.50, 1.00 and 2.00 µg a.s./bumblebee (corrected for purity). The resulting oral uptake was 0.12, 0.24, 0.46, 0.97 and 1.76 µg BAS 310 I/bumblebee. Additionally, bumblebees were treated with Dimethoate EC 400 as reference item at dose rates ranging from 0.25 to 1.50 µg dimethoate/bumblebee (nominal) or with 50% (w/v) sucrose solution and sucrose solution including 1% acetone as controls.

In the oral toxicity test, no mortality occurred in both control groups. In the test item treatment, statistically significant mortality of 53.3, 76.7 and 86.7% occurred after oral consumption of 0.46, 0.97 and 1.76 µg BAS 310 I/bumblebee, after 96 hours. Bumblebees in the dose rate of 0.24 µg consumed BAS 310 I/bumblebee revealed effects on mortality that amounted to 16.7%, whereas no mortality occurred in the lowest dose rate of 0.12 µg consumed BAS 310 I/bumblebee, after 96 hours. Behavioral abnormalities of surviving bumblebees occurred at the higher dose rates of 0.46, 0.97 and 1.76 µg consumed BAS 310 I/bumblebee. Surviving bumblebees showed symptoms of moribundity. No or only slight effects on behavior of surviving bumblebees occurred in the dose rates of 0.12 and 0.24 µg consumed BAS 310 I in the oral toxicity test when compared to the control

The toxicity of BAS 310 I on bumblebees was tested in an acute oral toxicity test. The LD_{50} (96 h) was determined to be 0.54 µg consumed product/bumblebee which is corresponding to 0.54 µg consumed a.s./bumblebee (corrected for purity).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 310 I, batch no. COD-000595; content: alpha-cypermethrin (BAS 310 I, Reg. No. 4 078 193): 99.2% (analyzed).

B. STUDY DESIGN

Test species: Bumblebee (*Bombus terrestris* L.), young adult worker bumblebees derived from a healthy and queen-right micro-hive; source: Biobest Belgium N.V., Westerlo, Belgium; delivered by: Katz Biotech AG, Baruth, Germany; collected from the bumblebee micro-hive in the morning prior to use; starving period: 3 hours.

Test design: In a 96-hour test, adults of *Bombus terrestris* L. were exposed to 5 dose rates of BAS 310 I in treated food (50% (w/v) sucrose solution). In total, 3 treatment groups were set up: 5 dose rates of the test item, two control groups and 4 dose rates of the reference item with 30 replicates per dose and 1 bumblebee per replicate. Assessments of bumblebee mortality and behavioral effects were done after 4, 24, 48, 72 and 96 hours.

Endpoints: Mortality, behavioral impairments.

Reference item: Dimethoate EC 400 (BAS 152 11 I, a.s.: dimethoate, 400 g/L nominal).

Test rates: Controls: 50% (w/v) sucrose solution, 50% (w/v) sucrose solution including 1% acetone; test item: 0.13, 0.25, 0.51, 1.01 and 2.02 µg BAS 310 I/bumblebee which is corresponding to 0.13, 0.25, 0.50, 1.00 and 2.00 µg a.s./bumblebee (corrected for purity); resulting in an actual uptake of 0.12, 0.24, 0.46, 0.97 and 1.76 µg BAS 310 I/bumblebee; reference item: 0.25, 0.46, 0.83 and 1.50 µg dimethoate/bumblebee.

Test conditions: Temperature: 24.9°C – 25.1°C; relative humidity: 57.5% - 60.9%, photoperiod: 24 h darkness, food: 50% (w/v) sucrose solution.

Statistics: Descriptive statistics. Fisher's Exact Binominal test with Bonferroni Correction for mortality data (one-sided greater, $\alpha = 0.05$), Probit analysis using linear weight regression and moving average computation after Thompson for calculation of the LD_{50} values.

II. RESULTS AND DISCUSSION

In the oral toxicity test, no mortality occurred in both control groups. In the test item treatment, statistically significant mortality of 53.3, 76.7 and 86.7% occurred after oral consumption of 0.46, 0.97 and 1.76 µg BAS 310 I/bumblebee, after 96 hours (Fisher's Exact Binominal test with Bonferroni Correction, one-sided greater, $\alpha = 0.05$). Bumblebees in the dose rate of 0.24 µg consumed BAS 310 I/bumblebee revealed effects on mortality that amounted to 16.7%, whereas no mortality occurred in the lowest dose rate of 0.12 µg consumed BAS 310 I/bumblebee, after 96 hours. Behavioral abnormalities of surviving bumblebees occurred at the higher dose rates of 0.46, 0.97 and 1.76 µg consumed BAS 310 I/bumblebee. Surviving bumblebees showed symptoms of moribundity. No or only slight effects on behavior of surviving bumblebees occurred in the dose rates of 0.12 and 0.24 µg consumed BAS 310 I in the oral toxicity test when compared to the control The results are summarized in Table 8.3.1.1.1-2.

Table 8.3.1.1.1-2: Toxicity of BAS 310 I to bumblebee (*Bombus terrestris* L.) in an oral toxicity test

Treatment [µg BAS 310 I/bumblebee]	**Uptake of test item [µg BAS 310 I/bumblebee]**	**Mean mortality [%]**			
		24 h	**48 h**	**72 h**	**96 h**
Control (sucrose)	--	0.0	0.0	0.0	0.0
Control (sucrose + acetone)	--	0.0	0.0	0.0	0.0
0.13	0.12	0.0	0.0	0.0	0.0
0.25	0.24	16.7	16.7	16.7	16.7
0.50	0.46	36.7*	53.3*	53.3*	53.3*
1.00	0.97	56.7*	66.7*	76.7*	76.7*
2.00	1.76	40.0*	73.3*	86.7*	86.7*
Endpoints					
LD_{50} (96 h) [1)]	**[µg consumed a.s./bumblebee]**		**[µg consumed product/bumblebee]**		
	0.54 (95% CL: 0.42 - 0.69)		0.54 (95% CL: 0.42 - 0.69)		

* Statistically significant differences compared to the control (Fisher's Exact Binominal test with Bonferroni Correction, $\alpha = 0.05$).

1) Median lethal dose calculated by Probit analysis (with 95% Confidence Limits).

The LD_{50} value (24 h) for the reference item in the oral toxicity test was determined to be 0.50 µg a.s./bumblebee.

III. CONCLUSION

The toxicity of BAS 310 I on bumblebees was tested in an acute oral toxicity test. The LD_{50} (96 h) was determined to be 0.54 µg consumed product/bumblebee which is corresponding to 0.54 µg consumed a.s./bumblebee (corrected for purity).

CA 8.3.1.1.2 Acute contact toxicity

Report:	CA 8.3.1.1.2/1 Barth M., 2006a Acute toxicity of BAS 310 I to the honeybee Apis mellifera L. under laboratory conditions 2005/1026137
Guidelines:	OECD 213, OECD 214
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

In a dose response test, young adult worker bees (*Apis mellifera* L.) were exposed to alpha-cypermethrin. The toxicity of the test product was determined in an contact test at concentrations of 0.200, 0.096, 0.046, 0.022 and 0.011 µg a.s./bee. Additionally, honeybees were treated with dimethoate as reference standard at concentrations ranging from 0.0625 to 0.50 µg a.s./bee. Three control treatments consisting of deionized water, acetone and 0.1% v/v Tween solution were carried out. The test was conducted with 3 replicates for the treatment groups; each of the test cages contained 10 bees. Assessment of mortality was done after 4, 24 and 48 hours. Additionally behavioral abnormalities were observed within 48 hours after contact exposure.

In the contact toxicity test (48 h) the average mortalities for the test item treatments of 0.200, 0.096, 0.046, 0.022 and 0.011 µg a.s./bee were 100, 93.3, 76.7, 33.3 and 6.7%, respectively. No mortality was observed in the control treatment groups.
Effects on behavior were observed in honeybees after contact exposure to doses of 0.011 up to 0.200 µg a.s./bee at the 4 hour assessment.
Within 48 hours after contact exposure to the test item bees had generally recovered and no different behavior for all surviving bees exposed up to a dose of 0.096 µg a.s./bee compared to control bees was observed.

The LD_{50} (48 h) was 0.030 µg (95% CL 0.025 - 0.036 µg alpha cypermethrin) a.s./bee in the contact toxicity test.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: alpha-cypermethrin (BAS 310 I, Reg. no. 4 078 193); batch COD-000166 (99.3%, analyzed).

B. STUDY DESIGN

Test species: Honeybee (*Apis mellifera carnica* L.), worker bees from a healthy and queen-right colony, age: 4 - 6 weeks, source: Bienenfarm Kern GmbH, Leipzig, Germany, collected in the morning of use and kept under test conditions.

Test design: Contact (LD_{50} test): 48 h; 5 treatment groups, 3 replicates each consisting 10 bees. The mortality was assessed 4, 24 and 48 h after application.

Endpoints: LD_{50}, behavioral abnormalities.

Reference item: Perfekthion EC 400 (dimethoate 408.7 g/L analyzed).

Test concentrations: 0.200, 0.096, 0.046, 0.022 and 0.011 µg a.s./bee.

Test conditions: Bees were kept in the dark at 24°C – 25°C (69% - 71% RH) in the contact test. Food: 50% w/v sucrose solution.

Statistics: Fisher's Exact Binomial Test with Bonferroni Correction for mortality data, $\alpha \leq 0.05$. Probit analysis according to the maximum likelihood method (FINNEY 1971) for calculation of the LD_{50} with 95 % confidence intervals. Statistical program used: ToxRat Professional 2.09 (2004)

II. RESULTS AND DISCUSSION

In the contact toxicity test no statistically significant effects on survival (6.7% mortality) were observed at the tested dose of 0.011 µg a.s./bee after 48 hours (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha \leq 0.05$). For the tested doses of 0.022, 0.046, 0.096 and 0.200 µg a.s./bee statistically significant effects of the test item on survival (33.3, 76.7, 93.3 and 100.0% mortality) were observed after 48 hours (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha \leq 0.05$). Therefore the LD_{50} (48 h) was calculated as 0.030 µg consumed a.s./bee in the contact toxicity test.
In the contact toxicity test effects on behavior were observed in honeybees after contact exposure to doses of 0.011 up to 0.200 µg a.s./bee at the 4 hour assessment.
Within 48 hours after contact exposure to the test item bees had generally recovered and no different behavior for all surviving bees exposed up to a dose of 0.096 µg a.s./bee compared to control bees was observed.

See results are summarized in Table 8.3.1.1.2-1.

Executive Summary

In a dose response test, young adult worker bumblebees (*Bombus terrestris* L.) were exposed to BAS 310 I. The acute toxicity of the test item was determined in a contact test at dose rates of 0.06, 0.13, 0.25, 0.51 and 1.01 µg BAS 310 I/bumblebee which is corresponding to 0.06, 0.13, 0.25, 0.50 and 1.00 µg a.s./bumblebee (corrected for purity). Additionally, bumblebees were treated with Dimethoate EC 400 as reference item at dose rates ranging from 2.5 to 10.0 µg dimethoate/bumblebee (nominal) or with deionized water, Tween solution and acetone as controls.

In the contact toxicity test, no mortality occurred in the control group treated with deionized water. After 96 hours of exposure 3.3% mortality occurred in the control groups treated with Tween solution and acetone. In the test item treatment, statistically significant mortality of 43.3, 76.7 and 100.0% occurred after thoracic application of 0.25, 0.51 and 1.01 µg BAS 310 I/bumblebee, after 96 hours. Bumblebees treated with 0.06 and 0.13 µg BAS 310 I/bumblebee revealed effects on mortality that amounted to 6.7 and 20.0%, after 96 hours. Behavioral abnormalities of surviving bumble bees occurred at the higher dose rates of 1.01 and 0.50 µg BAS 310 I/bumblebee. Surviving bumblebees showed symptoms of moribundity. In the other dose rates no effects on behavior of surviving bumblebees occurred when compared to the control.

The toxicity of BAS 310 I on bumblebees was tested in an acute contact toxicity test. The LD_{50} (96 h) was determined to be 0.29 µg product/bumblebee which is corresponding to 0.29 µg a.s./bumblebee (corrected for purity).

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 310 I, batch no. COD-000595; content: alpha-cypermethrin (BAS 310 I, Reg. No. 4 078 193): 99.2% (analyzed).

B. STUDY DESIGN

Test species: Bumblebee (*Bombus terrestris* L.), young adult worker bumblebees derived from a healthy and queen-right micro-hive; source: Biobest Belgium N.V., Westerlo, Belgium; delivered by: Katz Biotech AG, Baruth, Germany; collected from the bumblebee micro-hive in the morning prior to use.

Test design: In a 96-hour test, adults of *Bombus terrestris* were exposed to 5 doses of BAS 310 I in an appropriate carrier (Tween as wetting agent) placed on the dorsal bumblebee thorax. In total, 3 treatment groups were set up: 5 dose rates of the test item, 3 control groups and 4 dose rates of the reference item with 3 replicates per dose and 10 bumblebees per replicate, respectively.
Assessments of bumblebee mortality and behavioral effects were done after 4, 24, 48, 72 and 96 hours.

Endpoints: Mortality, behavioral impairments.

Reference item: Dimethoate EC 400 (BAS 152 11 I, a.s.: dimethoate, 400 g/L nominal).

Test rates: Controls: deionized water, 1.0 % (v/v) Tween solution, pure acetone; test item: 0.06, 0.13, 0.25, 0.51 and 1.01 µg BAS 310 I/bumblebee which is corresponding to 0.06, 0.13, 0.25, 0.50 and 1.00 µg a.s./bumblebee (corrected for purity); reference item: 2.5, 4.0, 6.3 and 10.0 µg dimethoate/bumblebee.

Test conditions: Temperature: 24.9°C – 25.1°C; relative humidity: 57.5% - 60.9%, photoperiod: 24 h darkness, food: 50% (w/v) sucrose solution.

Statistics: Descriptive statistics. Fisher's Exact Binominal test with Bonferroni Correction for mortality data (one-sided greater, $\alpha = 0.05$), Probit analysis using linear weight regression and linear maximum likelihood regression for calculation of the LD_{50} values.

II. RESULTS AND DISCUSSION

In the contact toxicity test, no mortality occurred in the control group treated with deionized water. After 96 hours of exposure 3.3% mortality occurred in the control groups treated with Tween solution and acetone. In the test item treatment, statistically significant mortality of 43.3, 76.7 and 100.0% occurred after thoracic application of 0.25, 0.51 and 1.01 µg BAS 310 I/bumblebee, after 96 hours (Fisher's Exact Binominal test with Bonferroni Correction, one-sided greater, $\alpha = 0.05$). Bumblebees treated with 0.06 and 0.13 µg BAS 310 I/bumblebee revealed effects on mortality that amounted to 6.7 and 20.0%, after 96 hours. Behavioral abnormalities of surviving bumblebees occurred at the higher dose rates of 1.01 and 0.50 µg BAS 310 I/bumblebee. Surviving bumblebees showed symptoms of moribundity. In the other dose rates no effects on behavior of surviving bumblebees occurred when compared to the control. The results are summarized in Table 8.3.1.1.2-2.

Table 8.3.1.1.2-2: Toxicity of BAS 310 I to bumblebee (*Bombus terrestris* L.) in a contact toxicity test

Treatment [µg BAS 310 I/bumblebee]	Mean mortality [%]				
	24 h	48 h	72 h	96 h	
Water	0.0	0.0	0.0	0.0	--
Tween	0.0	0.0	3.3	3.3	--
Acetone	0.0	0.0	0.0	3.3	0.0
0.06	0.0	0.0	3.3	6.7	3.5 [2)]
0.13	0.0	0.0	20.0*	20.0	17.2 [2)]
0.25	0.0	33.3*	40.0*	43.3*	41.4 *[2)]
0.51	0.0	50.0*	70.0*	76.7*	75.9 *[2)]
1.01	53.3*	86.7*	96.7*	100.0*	--
Endpoints					
LD_{50} (96 h) [1)]	[µg a.s./bumblebee]		[µg product/bumblebee]		
	0.29 (95% CL: 0.23 - 0.37)		0.29 (95% CL: 0.23 - 0.37)		

* Statistically significant differences compared to the control (Fisher's Exact Binominal test with Bonferroni Correction, $\alpha = 0.05$).

1) Median lethal dose calculated by Probit analysis (with 95% Confidence Limits).

2) Corrected mortality according to Schneider-Orelli, 1947.

The LD_{50} value (24 h) for the reference item in the contact toxicity test was determined to be 5.9 µg a.s./bumblebee.

III. CONCLUSION

The toxicity of BAS 310 I on bumblebees was tested in an acute contact toxicity test. The LD_{50} (96 h) was determined to be 0.29 µg product/bumblebee which is corresponding to 0.29 µg a.s./bumblebee (corrected for purity).

CA 8.3.1.2 Chronic toxicity to bees

Report:	CA 8.3.1.2/1 Sekine T., 2014a Chronic oral toxicity test of BAS 310 I on the honey bee (Apis mellifera L.) in the laboratory 2013/1132489
Guidelines:	OECD 213 (1998), CEB No. 230 (2003)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

In a 10-day chronic oral toxicity test, one day old worker honeybees (*Apis mellifera* L.) were exposed to a daily application of BAS 310 I diluted in the bee food (50 % (*w/w*) aqueous syrup solution). The test item BAS 310 I was daily administered to the bees in sugar solution at the following concentrations: 0.4, 1.0, 2.5, 6.25, and 15.625 mg a.s./kg food. The actual daily mean doses were 0.014, 0.033, 0.098, 0.35, and 1.13 µg a.s./bee/day after 10 days, corresponding to overall doses of 0.14, 0.33, 0.98, 3.2, and 6.8 µg a.s./bee. Untreated diet as well as diet treated with the solvent served as water and solvent controls, respectively.

After 10 days of exposure, a mean mortality of 3.3 % and 6.7 % were observed in the water and solvent control, respectively. In the test item group mean mortalities ranged between 20.0% at an actual dose of 0.04 µg a.s./bee/day and 100 % at the highest test dose. At a dose of 1.13 µg a.s./be/day bees displaying moving coordination problems and/or apathy were observed from day 1 to 3. A single surviving bee showed cramps on day 4 and 5 before dying. A dose of 0.35 µg a.s./bee/day led to moving coordination problems and/or apathy from day 2 to 9. 0.098 µg a.s./bee/day resulted in moving coordination problems and/or apathy from day 2 to 10. At a dose of 0.033 µg a.s./bee/day moving coordination problems and/or apathy were observed from day 2 to 10, except on day 8. At 0.014 µg a.s./bee/day only single bees showed uncoordinated movements on the days 2, 3, 5 and 6. Intensity and frequency of the behavioral abnormalities were dose dependent.

In a 10-day chronic toxicity feeding study with BAS 310 I, the $LD_{50\ (daily)}$ was determined to be 0.11 µg a.s./bee/day. Consequently, the LD_{50} for the entire testing period ($LD_{50\ (overall)}$) was 1.1 µg a.s./bee. This corresponds to a LC_{50} of 2.29 mg a.s./kg food.
The $NOED_{daily}$ was determined to be < 0.014 µg a.s./bee/day and the $NOED_{overall}$ < 0.14 µg a.s./bee. The NOEC was < 0.4 mg a.s./kg food.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: alpha-cypermethrin (BAS 310 I, Reg. no. 4 078 193); batch No.: COD-000595: 99.2 % (analyzed; tolerance ± 1.0 %).

B. STUDY DESIGN

Test species: Honey bee (*Apis mellifera* L.); young female worker bees (one day old); obtained from a healthy and queen-right colony, bred by IBACON, collected in the morning of use.

Test design: 10-day chronic oral feeding test in the laboratory (dose response test). Freshly emerged honey bees were daily provided with 5 freshly prepared doses of test item treated sugar solutions (50 % *w/w* Apiinvert) *ad libitum* over a period of 10 days. An untreated water control, a solvent control and a reference item were included in this study. 3 replicates per treatment, each consisting of 10 bees per test cage. Assessments of bee mortality and behavioral effects were done daily over the 10 days test period.

Endpoint: Mortality, behavioral impairments.

Reference item: BAS 152 11 I (Perfekthion EC), 400.0 g/L dimethoate (nominal).

Test concentrations: Control: untreated diet (50 % (*w*/*w*) aqueous syrup solution), solvent control: untreated diet with solvent (50 % (*w*/*w*) aqueous syrup solution plus 5 % acetone).
Test item: 15.625, 6.25, 2.5, 1.0 and 0.4 mg a.s./kg food. Target Dose Level: 0.625, 0.25, 0.1, 0.04 and 0.016 µg a.s/bee/day. Actual Mean Dose Level: 1.13, 0.35, 0.098, 0.033 and 0.014 µg a.s./bee/day (based on daily actual intake).
Reference item: 1 mg a.s./kg food. Target Dose Level: 0.04 µg a.s/bee/day. Actual mean dose level: 0.034 µg a.s/ bee/day (based on daily actual intake).

Test conditions: Temperature: 33°C – 34°C, mean relative humidity: 34 % – 78 %, photoperiod: darkness (except during assessments), food: 50 % aqueous syrup solution (Apiinvert, 30 %sucrose, 31 % glucose, 39 % fructose).

Statistics: Descriptive statistics; the LC_{50} as well as $LD_{50\ (daily)}$ and $LD_{50\ (overall)}$ values of the test item were estimated according to moving average computations (Thompson and Weil, 1952). The NOEC as well as the $NOED_{daily}$ and $NOED_{overall}$ of the test item were determined using Fisher's Exact Test (pairwise comparison, one-sided greater, $\alpha = 0.05$).

II. RESULTS AND DISCUSSION

In a chronic oral toxicity test, the test item BAS 310 I was daily administered to the honeybees via food at the following concentrations: 0.4, 1.0, 2.5, 6.25, and 15.625 mg a.s./kg food. The actual daily mean doses were 0.014, 0.033, 0.098, 0.35, and 1.13 µg a.s./bee/day after 10 days, corresponding to overall doses of 0.14, 0.33, 0.98, 3.2, and 6.8 µg a.s./bee.

Mortality occurred in all test item treated dose levels ranging from 20.0 % at a dose 0.033 µg a.s./bee/day to 100 % at the highest test dose at the test end. There was 3.3 % mortality in the water control and 6.7 % in the solvent control.
At a dose of 1.13 µg a.s./be/day, honeybees displaying moving coordination problems and/or apathy were observed from day 1 to 3. A single surviving bee showed cramps on day 4 and 5 before dying. A dose of 0.35 µg a.s./bee/day led to moving coordination problems and/or apathy from day 2 to 9. The dose of 0.098 µg a.s./bee/day resulted in moving coordination problems and/or apathy from day 2 to 10. At a dose of 0.033 µg a.s./bee/day, moving coordination problems and/or apathy were observed from day 2 to 10, except on day 8. At 0.014 µg a.s./bee/day only single bees showed uncoordinated movements on day 2, 3, 5 and 6. Intensity and frequency of the behavioral abnormalities were dose dependent. Because control mortality was ≤ 15 % and the mortality of the reference item was ≥ 50 % the test can be regarded as valid.

The results are summarized in Table 8.3.1.2-1 and Table 8.3.1.2-2.

0.098	0.98	2.5	46.7	42.9
0.35	3.2	6.25	100.0	100.0
1.13	6.8	15.625	100.0	100.0

Endpoints *		**10 days**
Test item dose	**$LD_{50\ (daily)}$**	0.11 µg a.s./bee/day (95 % CL: 0.071 – 0.18)
	$LD_{50\ (overall)}$	1.10 µg a.s./bee (95 % CL: 0.71 – 1.8)
	NOED (daily) 1)	< 0.014 µg a.s./bee/day
	NOED (overall) 1)	< 0.14 µg a.s./bee
Test item concentration [mg a.s./kg food]	**LC_{50}**	2.29 mg a.s./kg food (95 % CL: 1.56 – 3.36)
	NOEC 1)	< 0.4 mg a.s./kg food

* The LC_{50}/LD_{50} was estimated according to moving average computations, corrected by solvent control mortality using Abbott's formula; CL. = lower and upper confidence limits.

1) The NOEC/NOED was estimated using Fisher's Exact Test (pairwise comparison, one-sided greater, $\alpha = 0.05$).

The reference item dimethoate caused 100 % mortality at day 10 at a concentration 1 mg dimethoate/kg food (1 ppm), corresponding to an actual dose of 0.034 µg a.s./bee/day.

III. CONCLUSION

In a 10-day chronic toxicity feeding study with BAS 310 I, the $LD_{50\ (daily)}$ was determined to be 0.11 µg a.s./bee/day. Consequently, the LD_{50} for the entire testing period ($LD_{50\ (overall)}$) was 1.1 µg a.s./bee. This corresponds to a LC_{50} of 2.29 mg a.s./kg food.
The $NOED_{daily}$ was determined to be < 0.014 µg a.s./bee/day and the $NOED_{overall}$ < 0.14 µg a.s./bee. The NOEC was < 0.4 mg a.s./kg food.

CA 8.3.1.3 Effects on honeybee development and other honeybee life stages

The acute study on honeybee larvae (DocID 2014/1090816) was conducted, but was not valid and would need to be repeated in the bee season of 2015 in order to obtain a reliable endpoint. A new acute study could potentially be submitted at the end of September 2015. However, the submission already comprises a study addressing the repeated exposure to honeybee larvae (BASF DocID 2014/1162697). As just one of the bee larvae studies (acute or chronic) is required to address honeybee larvae in tier 1, the missing study is actually obsolete. Furthermore, the honeybee brood will be addressed in several higher tier studies (see chapter 10.3).

Report:	CA 8.3.1.3/1 Kleebaum K., 2014a Chronic toxicity of BAS 310 I honeybee larvae Apis mellifera L. under laboratory conditions (in vitro) 2014/1162697
Guidelines:	OECD 237 (2013) Honey bee (Apis mellifera) larval toxicity test single exposure, OECD Draft Test Guideline on Honey bee (Apis mellifera) Larval Toxicity Test Repeated Exposure (February 2014)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

In a chronic feeding toxicity test, honeybee larvae (*Apis mellifera* L.) were exposed to repeated applications of BAS 310 I (alpha-cypermethrin) diluted in the larvae food. The toxicity of the test item was determined at doses of 1.0, 2.0, 4.0, 6.0 and 8.0 ng a.s./larva (corresponding to 1.0, 2.0, 4.0, 6.0 and 8.1 ng product/larva). The concentrations of test item in the diet were 0.006, 0.013, 0.026, 0.039 and 0.052 mg a.s./kg food. Additionally, honeybee larvae were treated with dimethoate as reference item and with an untreated diet as well as with a diet treated with the solvent as controls, respectively.

In the larval toxicity test, the control group (untreated diet) showed a mortality of 0.0% after 96 hours (D7) and 5.6% after 120 hours (D8). The solvent control showed a mortality of 0.0% after 96 hours (D7) and 2.8% after 120 hours (D8). In the test item group, none of the larvae fed with 1.0, 2.0, 4.0, 6.0 and 8.0 ng a.s./larva revealed a mortality, which was statistically significantly different in comparison to the control groups after 96 hours (D7) and 120 hours (D8), respectively.

In a chronic larval toxicity test with BAS 310 I, the NOED (96 h and 120 h) was ≥ 8.0 ng a.s./larva and the corresponding NOEC (96 h and 120 h) ≥ 0.052 mg a.s./kg food. Accordingly, the LD_{50} (96 h) was determined to be > 8.0 ng a.s./larva, which is equivalent to a LC_{50} (96 h) of > 0.052 mg a.s./kg food. The LD_{50} (120 h) was calculated to be > 8.0 ng a.s./larva, which is equivalent to a LC_{50} (120 h) of > 0.052 mg a.s./kg food.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: alpha-cypermethrin (BAS 310 I, Reg. no. 4 078 193); batch no.: COD-000595: 99.2 % (analyzed; tolerance ± 1.0 %).

B. STUDY DESIGN

Test species: *Apis mellifera iberica* P. (honeybee), synchronized first instar larvae (L1, one day old); derived from three healthy and queen-right colonies; source: Beekeeper Joaquin Cordero, Cazalla (Sevilla), Spain.

Test design: One day old honeybee larvae (D1) of *Apis mellifera* L. were transferred from brood combs to polystyrene grafting cells in 48-well cell culture plates 3 days before start of the treatment. On 4 successive days (D3 to D6) the larvae were chronically exposed to BAS 310 I diluted in the larvae food (aqueous sugar solution mixed with royal jelly). After these applications no additional feeding of the larvae has been carried out. In total, 3 treatment groups were set up: 5 doses of the test item, 2 untreated control groups and 1 dose of the reference item with 3 replicates per dose and 12 larvae per replicate. Assessments of larval mortality were done after 24, 48, 72, 96 and 120 hours (respectively D4, D5, D6, D7 and D8). Additionally other observations as small body size or large quantities of remaining food after 96 and 120 hours (on D7 and D8) were noted. In an analytical phase of the study the concentration of the active substance in the test item base stock solution was determined.

Endpoints: Mortality, quantitative observations: body size, remaining food.

Reference item: Dimethoate tech. (analysed purity: 99.8 % w/w).

Test concentrations: Control: untreated diet (50% aqueous sugar solution + 50% royal jelly), solvent control: diet containing 2% v/v acetone; BAS 310 I: 1.0, 2.0, 4.0, 6.0 and 8.0 ng a.s./larva (corresponding to 1.0, 2.0, 4.0, 6.0 and 8.1 ng product/larva), the concentrations of test item in the diet were 0.006, 0.013, 0.026, 0.039 and 0.052 mg a.s./kg food; reference item: 6.2 µg dimethoate/larva.

Test conditions: Temperature: 34.0°C – 34.7°C, relative humidity: 95.2% - 95.8%, photoperiod: darkness (except during assessments), food: 50% aqueous sugar solution and 50% royal jelly.

Statistics: Descriptive statistics; Fisher's Exact Binominal test with Bonferroni Correction for mortality results and for determination of NOEC/NOED (one-sided greater, $\alpha = 0.05$).

II. RESULTS AND DISCUSSION

In the larval toxicity test, the control group (untreated diet) showed a mortality of 0.0% after 96 hours (D7) and 5.6% after 120 hours (D8). The solvent control showed a mortality of 0.0% after 96 hours (D7) and 2.8% after 120 hours (D8). In the test item group, none of the larvae fed with 1.0, 2.0, 4.0, 6.0 and 8.0 ng a.s./larva revealed a mortality, which was statistically significantly different in comparison to the control groups after 96 hours (D7) and 120 hours (D8), respectively. The results are summarized in Table 8.3.1.3-1.

Table 8.3.1.3-1: Toxicity of BAS 310 I to *Apis mellifera* L. in an acute larval toxicity test

Treatment		Mortality after 96 hours (D7)			Mortality after 120 hours (D8)		
Dosage [ng a.s./larva]	Concentration [mg a.s./kg food]	mean mortality [%] absolute	mean mortality [%] corrected [1]	mean OO [%] [2]	mean mortality [%] absolute	mean mortality [%] corrected [1]	mean OO [%] [2]
Control	Control	0.0	--	0.0	5.6	--	0.0
Solvent control	Solvent control	0.0	--	0.0	2.8	--	0.0
1.0	0.006	5.6	--	0.0	5.6	2.9	9.1
2.0	0.013	5.6	--	26.0	5.6	2.9	6.1
4.0	0.026	2.8	--	22.5	5.6	2.9	6.1
6.0	0.039	8.3	--	39.1	13.9	11.4	15.9
8.0	0.052	8.3	--	30.3	8.3	5.7	21.2

Endpoints		96 hours (D7)	120 hours (D8)
Test item dose [ng a.s./larva]	LD_{50}	> 8.0	> 8.0
	NOED [3]	≥ 8.0	≥ 8.0
Test item concentrations [mg a.s./kg food]	LC_{50}	> 0.052	> 0.052
	NOEC [3]	≥ 0.052	≥ 0.052

[1] Corrected mortality (according to Schneider-Orelli 1947).

[2] OO: Other observations (large quantities of remaining food, smaller body size of larva); Calculation are performed with non-rounded values.

[3] Fisher's Exact Binominal test with Bonferroni Correction, $\alpha = 0.05$, one sided greater.

In the reference item treatment group of 6.2 µg dimethoate/larva a mortality of 61.1% on D7 and 61.1% (corrected by control mortality: 58.8%) on D8 was determined.

III. CONCLUSION

In a chronic larval toxicity test with BAS 310 I, the NOED (96 h and 120 h) was ≥ 8.0 ng a.s./larva and the corresponding NOEC (96 h and 120 h) ≥ 0.052 mg a.s./kg food. Accordingly, the LD_{50} (96 h) was determined to be > 8.0 ng a.s./larva, which is equivalent to a LC_{50} (96 h) of > 0.052 mg a.s./kg food. The LD_{50} (120 h) was calculated to be > 8.0 ng a.s./larva, which is equivalent to a LC_{50} (120 h) of > 0.052 mg a.s./kg food.

CA 8.4.1 Earthworms – sub-lethal effects

Report: CA 8.4.1/1
Friedrich S., 2014b
Sublethal toxicity of BAS 310 I (Alpha-Cypermethrin) to the earthworm Eisenia fetida in artificial soil
2014/1135439
Guidelines: OECD 222 (2004)
GLP: yes
(certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of BAS 310 I (alpha-cypermethrin) on mortality, biomass development and reproduction were investigated in an extended laboratory study over 56 days. Five test concentrations (0.25, 0.5, 1, 2, 4 mg a.s./kg dry soil) were incorporated into the soil (10% peat) with four replicates per treatment (each containing 10 worms). An untreated control with 8 replicates was included. The reference item was tested in a separate study. Assessment of worm mortality, body weight and feeding activity was carried out after 28 days, assessment of reproduction (number of juveniles) was carried out after 56 days.

BAS 310 I (alpha-cypermethrin) did not show any statistically significant effects compared to the control on mortality and body weight. The mortality of adult worms was 0 – 2.5% in the treated variants and 1.3% in the control group. The weight change of adult worms was about 25.9 – 29.4% in the treated variants and 28.6% in the control group. The reproduction rates were not statistically significantly different compared the control up to and including a concentration of 4 mg a.s./kg dry soil. No behavioral abnormalities were observed in any of the treatment groups. The feeding activity in all the treated groups was comparable to the control.

In a 56-day earthworm reproduction study with BAS 310 I (alpha-cypermethrin), no adverse effects on survival, biomass development and reproduction could be determined at concentrations up to and including 4 mg a.s./kg dry soil. The NOEC for mortality, biomass and reproduction was determined to be ≥ 4 mg a.s./kg dry soil, the highest concentration tested.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 310 I (alpha-cypermethrin); batch no.: COD-000595; purity: 99.2% (tolerance ± 1.0%) (analyzed).

B. STUDY DESIGN

Test species:	Earthworm (*Eisenia fetida*), adult worms (with clitellum and weight of 254 – 443 mg/worm), approximately 3 months old; source: W. Neudorff GmbH KG, followed by in-house culture.
Test design:	56-day test in treated artificial soil according to OECD 222 (10% peat), different concentrations of the test item were incorporated into the soil; 6 treatment groups (5 test item concentrations, control); 4 replicates for the test item treatments, 8 replicates for the control, 10 worms each. Assessment of adult worm mortality, behavioral effects and biomass development after 28 days was done. Reproduction rate after additional 28 days (assessed 56 days after application) was determined.
Endpoints:	Mortality, weight change, feeding activity and reproduction rate.
Reference item:	Nutdazim 50 Flow (carbendazim, SC 500). The effects of the reference item were investigated in a separate study.
Test concentrations:	0.25, 0.5, 1, 2, 4 mg a.s./kg dry soil (based on analyzed purity).
Test conditions:	Artificial soil according to OECD 222 (with 10% peat); pH 6.00 – 6.05 at test initiation, 5.68 – 5.74 at test termination; water content 56.0 – 56.2% of maximum water holding capacity (WHC) at test initiation and 55.1 – 56.2% of WHC at test termination; temperature: 18.1 – 19.6°C; photoperiod: 16 h light : 8 h dark, light intensity: 540 lux.
Statistics:	Fisher's Exact Binomial Test for mortality ($\alpha = 0.05$, one-sided greater), Williams-t-test for weight change and reproduction ($\alpha = 0.05$, one-sided smaller).

II. RESULTS AND DISCUSSION

BAS 310 I (alpha-cypermethrin) did not show any statistically significant effects compared to the control on mortality and body weight (Fisher's Exact Binomial Test ($\alpha = 0.05$, one-sided greater) for mortality and Williams-t-test for weight change ($\alpha = 0.05$, one-sided smaller)). The mortality of adult worms was 0 – 2.5% in the treated variants and 1.3% in the control group. The weight change of adult worms was about 25.9 – 29.4% in the treated variants and 28.6% in the control group.

The reproduction rates were not statistically significantly different compared the control up to and including a concentration of 4 mg a.s./kg dry soil (Williams-t-test for reproduction ($\alpha = 0.05$, one-sided smaller)). No behavioral abnormalities were observed in any of the treatment groups. The feeding activity in all the treated groups was comparable to the control. The results are summarized in Table 8.4.1-1.

Table 8.4.1-1: Effects of BAS 310 I (alpha-cypermethrin) on earthworms (*Eisenia fetida)* in a 56-day reproduction study

BAS 310 I [mg a.s./kg dry soil]	**Control**	**0.25**	**0.5**	**1**	**2**	**4**
Mortality (day 28) [%]	1.3	0.0	2.5	0.0	0.0	2.5
Weight change (day 28) [%]	28.6	29.4	25.9	29.0	26.9	26.9
No. of juveniles (day 56)	135.8	143.3	130.3	120.8	129.0	111.5
Reproduction (day 56) [% of control]	100	105.5	95.9	89.0	95.0	82.1
Endpoints [mg a.s./kg dry soil]						
NOEC (day 28)	≥ 4					
NOEC (day 56)	≥ 4					

In a separate study the reference item Nutdazim 50 Flow had a significant effect on biomass increase and reproduction of *Eisenia fetida*. The reproduction rate was clearly inhibited by 39% and 100% compared to the control at the tested concentrations of 5 and 10 mg product/kg dry soil.

III. CONCLUSION

In a 56-day earthworm reproduction study with BAS 310 I (alpha-cypermethrin), no adverse effects on survival, biomass development and reproduction could be determined at concentrations up to and including 4 mg a.s./kg dry soil. The NOEC for mortality, biomass and reproduction was determined to be ≥ 4 mg a.s./kg dry soil, the highest concentration tested.

Report:	CA 8.4.1/2 Witte B., 2014a Effects of Reg.No. 130213 (metabolite of BAS 310 I, Alpha-cypermethrin, CL 206128) on reproduction and growth of earthworms Eisenia fetida in artificial soil 2014/1135451
Guidelines:	OECD 222 - Earthworm reproduction Test (2004), ISO 11268-2 (2012)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The effects of Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin; CL 206128) on mortality, biomass development and reproduction of the earthworm *Eisenia fetida* (Annelida: Oligochaeta) were investigated in a laboratory study over 56 days. Seven concentrations (0.12, 0.31, 0.77, 1.92, 4.8, 12 and 30 mg CL 206128/kg dry soil) were incorporated into the soil with four replicates per treatment (each containing 10 worms). An untreated control with 8 replicates was included. The reference item was tested in a separate study. Assessment of worm mortality, body weight and feeding activity was carried out after 28 days, assessment of reproduction (number of juveniles) was carried out after 56 days.

No mortality was observed in any treatment group. The body weight changes of the earthworms after 4 weeks exposure to CL 206128 were not statistically significantly different compared to the control up to and including the highest test concentration of 30 mg/kg dry soil. The reproduction rates were not statistically significantly different compared to the control up to and including the test concentration of 4.8 mg/kg dry soil. At the test concentration of 12 mg/kg dry soil and above the reproduction was statistically significantly reduced compared to the control. No behavioral abnormalities were observed in any of the treatment groups. The feeding activity in all the treated groups was comparable to the control.

In an earthworm reproduction and growth study with Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) the No Observed Effect Concentration (NOEC) for mortality, growth and feeding activity of the earthworm *Eisenia fetida* was equal to or greater than 30 mg/kg dry soil, *i.e.* the highest concentration tested. The No Observed Effect Concentration (NOEC) for reproduction was determined to be 4.8 mg/kg dry soil. The EC_{10} was determined to be 8.3 mg/kg dry soil and the EC_{20} was determined to be 35.0 mg/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin; CL 206128); batch no.: AC12251-34; purity: 100.0% (tolerance ± 1.0%).

B. STUDY DESIGN

Test species: Earthworm (*Eisenia fetida*), adult worms (with clitellum and weight range 300 to 600 mg), approximately 10 months old, source: in-house culture.

Test design: 56-day test in treated artificial soil prepared according to OECD 222; different concentrations of the test item were incorporated into the soil; 8 treatment groups (7 test item concentrations, control); 4 replicates for the test item treatments and 8 replicates for the control with 10 worms each. Assessment of adult worm mortality, behavioral effects and biomass development was carried out after 28 days exposure of adult worms in treated artificial soil. Reproduction rate (number of offspring) was assessed after additional 28 days (assessed 56 days after application).

Endpoints: Mortality, weight change, feeding activity and reproduction rate.

Reference item: Carbendazim (499 g/kg nominal). The effects of the reference item were investigated in a separate study.

Test concentrations: Control, 0.12, 0.31, 0.77, 1.92, 4.8, 12 and 30 mg Reg. No. 130 213/kg dry soil.

Test conditions: Artificial soil according to OECD 222; pH 6.0 to 6.2 at test initiation, pH 6.0 to 6.1 at test termination; water content 51.7% - 57.4% of maximum water holding capacity (WHC) at test initiation and 54.6% - 59.6% of the maximum WHC at test termination; temperature: 18°C - 22°C; photoperiod: 16 h light : 8 h dark, light intensity: within the range of 400 - 800 lux.

Statistics: Descriptive statistics, Williams t-test (α = 0.05, two-sided for body weight change and one-sided smaller for reproduction). Probit analysis for EC_x values.

II. RESULTS AND DISCUSSION

No mortality was observed in any treatment group. The body weight changes of the earthworms after 4 weeks exposure to CL 206128 were not statistically significantly different compared to the control up to and including the highest test concentration of 30 mg/kg dry soil (Williams t-test, α = 0.05, two-sided).
The reproduction rates were not statistically significantly different compared to the control up to and including the test concentration of 4.8 mg/kg dry soil (Williams t-test, α = 0.05, one-sided smaller). At the test concentration of 12 mg/kg dry soil and above the reproduction was statistically significantly reduced compared to the control. No behavioral abnormalities were observed in any of the treatment groups. The feeding activity in all the treated groups was comparable to the control. The results are summarized in Table 8.4.1-2.

Table 8.4.1-2: Effects of CL 206128 on earthworms (*Eisenia fetida)* in a 56-day reproduction study

CL 206128 [mg/kg dry soil]	**Control**	**0.12**	**0.31**	**0.77**	**1.92**	**4.8**	**12**	**30**
Mortality (day 28) [%]	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Weight change (day 28) [%]	43.9	39.7	42.1	41.3	41.8	43.5	41.4	42.5
No. of juveniles (day 56)	221	226	233	195	224	211	194 *	178 *
Reproduction (day 56) [% of control]	--	102.0	105.1	87.9	101.2	95.5	87.7	80.3
Food consumption [g]	25.0	25.0	25.0	25.0	25.0	25.0	25.0	25.0
Endpoints [mg/kg dry soil]								
NOEC (day 28) (mortality and weight)	≥ 30							
NOEC (day 56) (reproduction)	4.8							
EC_{10} [1)]	8.3							
EC_{20} [1)]	35.0							

* Statistically significantly different compared to the control (Williams-t-test, α = 0.05, one-sided smaller).
1) Probit analysis.

In the most recent test with the reference item, there were statistically significant effects on reproduction at a concentration of 1.95 mg carbendazim/kg soil and higher, which is in line with the guideline OECD. The EC_{50} for reproduction was calculated to be 1.87 mg carbendazim/kg dry soil.

III. CONCLUSION

In an earthworm reproduction and growth study with Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) the No Observed Effect Concentration (NOEC) for mortality, growth and feeding activity of the earthworm *Eisenia fetida* was equal to or greater than 30 mg/kg dry soil, *i.e.* the highest concentration tested. The No Observed Effect Concentration (NOEC) for reproduction was determined to be 4.8 mg/kg dry soil. The EC_{10} was determined to be 8.3 mg/kg dry soil and the EC_{20} was determined to be 35.0 mg/kg dry soil.

Report:	CA 8.4.1/3 Witte B., 2014b Effects of Reg.No. 4080830 (metabolite of BAS 310 I, Alpha-cypermethrin; CL 912554) on reproduction and growth of earthworms Eisenia fetida in artificial soil 2014/1135452
Guidelines:	OECD 222 (2004), ISO 11268-2 (2012)
GLP:	yes (certified by Hessisches Ministerium fuer Umwelt, Energie, Landwirtschaft und Verbraucherschutz, Wiesbaden)

Executive Summary

The effects of Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin; CL 912554) on mortality, biomass development and reproduction of the earthworm *Eisenia fetida* (Annelida: Oligochaeta) were investigated in a laboratory study over 56 days. Five concentrations (6.25, 12.5, 25, 50 and 100 mg CL 912554/kg dry soil) were incorporated into the soil with four replicates per treatment each containing 10 worms. An untreated control with 8 replicates was included. The reference item was tested in a separate study. Assessment of worm mortality, body weight and feeding activity was carried out after 28 days, assessment of reproduction (number of juveniles) was carried out after 56 days.

No mortality was observed in any treatment group. The body weight changes were not statistically significantly different compared to the control up to and including the concentration of 12.5 mg/kg dry soil. At the concentration of 25 mg/kg dry soil and above the body weight change was statistically significantly reduced compared to the control. The reproduction rates were not statistically significantly different compared to those in the control at the concentration of 6.25 mg/kg dry soil. At the concentration of 12.5 mg/kg dry soil and above the reproduction was statistically significantly reduced compared to the control. No behavioral abnormalities were observed in any of the treatment groups, except at the highest test item treated group of 100 mg/kg dry soil, where the adult worms after 28 days were tensed and coiled. The feeding activity in all the treated groups was comparable to the control, except at the highest test concentration of 100 mg/kg dry soil the food intake was slightly reduced.

In a 56-day earthworm reproduction study with Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin; CL 912554) the NOEC for mortality was equal to or greater than 100 mg/kg dry soil, the NOEC for biomass was 12.5 mg/kg dry soil and the NOEC for reproduction was 6.25 mg/kg dry soil. The EC_{10} was determined to be 14.8 mg/kg dry soil, the EC_{20} was determined to be 21.0 mg/kg dry soil and the EC_{50} was determined to be 40.8 mg/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin; CL 912554); batch no.: AC12717-65; purity: 99.5% (tolerance ± 1.0%) (analyzed).

B. STUDY DESIGN

Test species: Earthworm (*Eisenia fetida*), adult worms (with clitellum and weight 300 - 576 mg), approximately 7 months old, source: in-house culture.

Test design: 56-day test in treated artificial soil prepared according to OECD 222; different concentrations of the test item were incorporated into the soil; 6 treatment groups (5 test item concentrations, control); 4 replicates for the test item treatments and 8 replicates for the control with 10 worms each. Assessment of adult worm mortality, behavioral effects and biomass development was carried out after 28 days exposure of adult worms in treated artificial soil. Reproduction rate (number of offspring) was assessed after additional 28 days (assessed 56 days after application).

Endpoints: Mortality, weight change, feeding activity and reproduction rate.

Reference item: Carbendazim (499 g/kg nominal). The effects of the reference item were investigated in a separate study.

Test concentrations: Control, 6.25, 12.5, 25, 50 and 100 mg CL 912554/kg dry soil.

Test conditions: Artificial soil according to OECD 222; pH 5.6 - 5.7 at test initiation, pH 5.8 - 6.1 at test termination; water content 53.4% - 53.8% of maximum water holding capacity (WHC) at test initiation and 54.7% to 60.9% of the maximum WHC at test termination; temperature: 18°C - 22°C; photoperiod: 16 h light : 8 h dark, light intensity: 400 - 800 lux.

Statistics: Descriptive statistics. Fisher's Exact Test ($\alpha = 0.05$, one-sided smaller) for mortality, Williams t-test ($\alpha = 0.05$, two-sided) for body weight change, Bonferroni-Welch t-test ($\alpha = 0.05$, one-sided smaller) for reproduction, Probit analysis (EC_x).

II. RESULTS AND DISCUSSION

No mortality was observed in any treatment group.

The body weight changes were not statistically significantly different compared to the control up to and including the concentration of 12.5 mg/kg dry soil. At the concentration of 25 mg/kg dry soil and above the body weight change was statistically significantly reduced compared to the control (Williams t-test, $\alpha = 0.05$, two-sided).

The reproduction rates were not statistically significantly different compared to those in the control at the concentration of 6.25 mg/kg dry soil. At the concentration of 12.5 mg/kg dry soil and above the reproduction was statistically significantly reduced compared to the control (Bonferroni-Welch t-test, $\alpha = 0.05$, one-sided smaller).

No behavioral abnormalities were observed in any of the treatment groups, except at the highest test item treated group of 100 mg/kg dry soil, where the adult worms after 28 days were tensed and coiled. The feeding activity in all the treated groups was comparable to the control, except at the highest test concentration of 100 mg/kg dry soil the food intake was slightly reduced. Results are summarized in Table 8.4.1-3.

Table 8.4.1-3: Effects of CL 912554 on earthworms (*Eisenia fetida)* in a 56-day reproduction study

CL 912554 [mg/kg dry soil]	**Control**	**6.25**	**12.5**	**25**	**50**	**100**
Mortality (day 28) [%]	0.0	0.0	0.0	0.0	0.0	0.0

NOEC (day 28) (weight)	12.5					
NOEC (day 56) (reproduction)	6.25					
EC_{10}[1)] (day 56)	14.8					
EC_{20}[1)] (day 56)	21.0					
EC_{50}[1)] (day 56)	40.8					

* Statistically significantly different compared to the control (Williams-t-test, $\alpha = 0.05$, two-sided).
** Statistically significantly different compared to the control (Bonferroni-Welch t-test, $\alpha = 0.05$, one-sided smaller).
1) Probit analysis.

In the most recent test with the reference item carbendazim, there were statistically significant effects on reproduction at a concentration of 1.95 mg carbendazim/kg dry soil and higher, which is in line with the guideline OECD 222. The EC_{50} for reproduction was calculated as 1.87 mg carbendazim/kg dry soil.

III. CONCLUSION

In a 56-day earthworm reproduction study with Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554) the NOEC for mortality was equal to or greater than 100 mg/kg dry soil, the NOEC for biomass was 12.5 mg/kg dry soil and the NOEC for reproduction was 6.25 mg/kg dry soil. The EC_{10} was determined to be 14.8 mg/kg dry soil, the EC_{20} was determined to be 21.0 mg/kg dry soil and the EC_{50} was determined to be 40.8 mg/kg dry soil.

From the performed literature search, the following peer-reviewed scientific study on non-target soil invertebrates was considered relevant for the terrestrial risk assessment of alpha-cypermethrin. Due to the unrealistic high concentration of alpha-cypermethrin tested in the study it was classified as being "not reliable" (Reliability Index (RI) 3). For details please see the literature search and evaluation files also provided in the submission package for Annex I Renewal. Nevertheless, the study is quite reasonably performed and in general to a certain extent comparable with current guidelines (e.g. ISO 11267:1999). Thus, the endpoints for the relevant species *Eisenia fetida* and *Folsomia candida* are presented as additional information for the terrestrial risk assessment and have not been evaluated previously.

Report:	CA 8.4.1/4 Hartnik T. et al., 2007b Toxicity of the pesticide Alpha-Cypermethrin to four soil nontarget invertebrates and implications for risk assessment 2007/1070505
Guidelines:	none
GLP:	no

Executive Summary

The aim of this toxicity study was to assess acute and chronic effects of alpha-cypermethrin on different soil invertebrate species. In this abstract the focus is on the effects of alpha-cypermethrin on the relevant test species, i.e. the earthworm *Eisenia fetida* and the soil non-target arthropod *Folsomia candida.* Other issues discussed in the paper (*i.e.* the comparison to aquatic toxicity and the effects of alpha-cypermethrin on other non-target soil invertebrate species) are not summarized here, because there are no comparable endpoints, no relevant species and not relevant for the risk assessment.

Tests were conducted in test soil spiked with alpha-cypermethrin. All tests were performed according to standardized OECD or International Organization for Standardization (ISO) guidelines except that natural soil was used instead of artificial OECD soil. For the assay with *E. fetida*, soil concentrations of 7.5, 30, 100, 300, and 1000 mg a.s./kg dry soil and for the assay with *F. candida*, nominal soil concentrations of 0.9, 3, 9, 30, 90, and 300 mg a.s./kg dry soil were used. For all tests, the test item concentrations were mixed thoroughly into the batch of soil.

All tests passed the validity criteria of the test protocols. For adult *E. fetida*, a LC_{50} value of 762 mg a.s./kg dry soil, was estimated. For springtails, the LC_{50} value was considerably higher than 258 mg a.s./kg dry soil, the highest concentration used in the test (for springtails, because lethality was less than 15% in this treatment.

Bioassays with the two invertebrate species *Eisenia fetida* and *Folsomia candida* in soil showed that despite a low acute toxicity, alpha-cypermethrin has a profound chronic toxicity toward soil-living organisms.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (technical grade; purity: 97.6%) provided by Inter-Trade Denmark (Bindslev, Denmark).

B. STUDY DESIGN

Test species: Earthworms *Eisenia fetida* (adults aged 24 - 30 weeks with a well-developed clitellum), springtails *Folsomia candida* (aged 10-12 days).

Test design: Different concentrations of the test item were incorporated into the test soil. For each bioassay, five (for *E. fetida*) and six (for *F. candida*) concentration levels, ranging from 7.5 to 1000 and from 0.9 to 300 mg alpha-cypermethrin/kg dry soil for *E. fetida* and *F. candida*, were mixed homogenously into the soil, respectively.
Reproduction test with *E. fetida:* A modified version of OECD 222 was used. Three replicates of 600 g of spiked soil per concentration level were used; for the controls, six replicates were prepared. Each replicate contained 10 worms weighing 372 ± 28 mg at test start. Cocoon production and mortality were assessed after 28 d.
Reproduction test with *F. candida:* A modified version of ISO 11267 was used in natural test soil. Four replicates for each test item concentration, six replicates for the control, each replicate containing 10 collembolans. Mortality (number of surviving adults) and number of living juveniles were assessed after 21 d.

Endpoints: Mortality and effects on reproduction were determined.

Test concentrations: *E. fetida*: 7.5, 30, 100, 300, and 1000 mg a.s./kg dry soil;
F. candida: 0.9, 3.0, 9.0, 30, 90, and 300 mg a.s./kg dry soil;

Test conditions: All tests were performed in natural test soil.
E. fetida: temperature: 20 ±2°C; photoperiod: 16:8-h light:dark; culture medium: mixture of sphagnum peat, potting soil, and chopped vegetables.

F. candida: 20 ±2°C; photoperiod: 16:8-h light:dark; cultured on artificial substrate; food: baker's yeast.

Test soil:

Parameter	**Soil type: sandy loam**
Organic carbon (g/100 g dry soil)	2.2
pH	6.5
Sand /silt / clay (%)	72.4 / 17.5 / 10.1
Water holding capacity (%)	34
Cation exchange capacity ($mmol_c$ (+)/kg)	132
Base saturation (%)	100
Exchangeable acidity ($mmol_c$ (+)/kg)	< 0.1

Statistics: Descriptive statistics; ANOVA followed by Dunnett's test ($\alpha = 0.05$) for determination of no-observed-effect concentration (NOEC) for sublethal endpoints (JMP, Ver 5.0; SAS Institute, Cary, NC, USA). Non-linear regression analysis for dose-response functions (GraphPad Prism, Ver 4.0; GraphPad Software, San Diego, CA, USA). Median effect concentrations (EC_{50}) was estimated by iteration using the three-parametric sigmoidal function.

II. RESULTS AND DISCUSSION

All tests passed the validity criteria of the test protocols. For adult *E. fetida*, a LC_{50} value of 762 mg a.s./kg dry soil, was estimated. For springtails, the LC_{50} value was considerably higher than 258 mg a.s./kg dry soil, the highest concentration used in the test (for springtails, because lethality was less than 15% in this treatment. A summary of the results is presented in the table below.

Table 8.4.1-4: Calculated toxicity parameters (median lethal concentration LC_{50}, median effective concentration EC_{50}, 10% effective concentration EC_{10}, and no-observed-effect concentrations, NOEC) of alpha-cypermethrin for *Eisenia fetida* and*Folsomia candida* [#]

Test species	LC_{50} [mg a.s./kg dry soil]	EC_{50} [mg a.s./kg dry soil]	EC_{10} [mg a.s./kg dry soil]	NOEC [mg a.s./kg dry soil]
Eisenia fetida	762 (510 - 1139)	31.0 (14.8 - 68.0)	1.57 (-1.01 - 4.15)	< 4.65
Folsomia candida	> 258	60.3 (32.0 - 113)	3.69 (-0.87 - 8.24)	8.43

[#] Ranges in parentheses represent the 95% confidence intervals.

III. CONCLUSION

Bioassays with the two invertebrate species (*Eisenia fetida* and *Folsomia candida*) in soil showed that despite a low acute toxicity, alpha-cypermethrin has a profound chronic toxicity toward soil-living organisms.

From the performed literature search, the following peer-reviewed scientific study on non-target soil invertebrates was considered as relevant for the terrestrial risk assessment of alpha-cypermethrin. Due to the unrealistic high concentration of alpha-cypermethrin tested in the study and the extrapolated endpoints it was classified as being “not reliable” (Reliability Index (RI) 3), as these endpoints are not measured but had been calculated far below the tested concentrations. For details please see the literature search and evaluation files also provided in the submission package for Annex I Renewal. Nevertheless, the study, but the study may be used as supplemental information as it was in general quite reasonably performed and to a certain extent comparable with current guidelines (e.g. OECD guideline 222). Thus, the endpoints for the relevant species *Eisenia fetida* and *Hypoaspis aculeifer* are presented as additional information for the terrestrial risk assessment and have not been evaluated previously.

Report: CA 8.4.1/5
Sechi V. et al., 2013b
Species composition of a soil invertebrate multi-species test system determines the level of ecotoxicity
2013/1417920
Guidelines: none
GLP: no
(certified by none)

Executive Summary

The system was capable of detecting population dynamics and species interactions not present in single species tests, and included interactions between faunal and microbial communities. More relevant here was the aim of the study to test the performance of two different non-target species in soil spiked with a range of alpha-cypermethrin concentrations. In this abstract the focus is on the effects of alpha-cypermethrin on the relevant test species, i.e. the earthworm *Eisenia fetida* and the soil non-target arthropod *Hypoaspis aculeifer*. The effects on other species which are not relevant for the risk assessment are not summarized here as there are no comparable endpoints as well as extrapolated (no measured) endpoints. Therefore these species as well as their endpoints are not relevant for the risk assessment.

The two different communities responded differently to the insecticide treatments. Alpha-cypermethrin had a general negative effect on the soil fauna, i.e. the soil non-target arthropod *Hypoaspis aculeifer and* the fresh body weight of *E. fetida*. The two different communities responded in a different manner to the insecticide. A positive effect due to the presence of the earthworms in the COM-F was observed, where in contrast the predator mite was more abundant in the COM-C.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Alpha-cypermethrin (technical grade; purity, 97.6%), provided by Inter-Trade Denmark (Bindslev, Denmark)

B. STUDY DESIGN

Test species relevant:

Functional group	Species	No. individuals	No. individuals m^{-2}
Predator mite	*Hypoaspis aculeifer*	10 females	1270
Lumbricid detrivore	*Eisenia fetida*	5 juveniles	635

Test design:	Two different faunal communities (COM-F, COM-C) were constructed, including three trophic levels and different functional groups. Both communities included the predator mite *Hypoaspis aculeifer,* but differed concerning the earthworms as only into one juveniles of the earthworm *Eisenia fetida* were added (COM-F). Besides a non-spiked control, three different alpha-cypermethrin concentrations were used. Due to technical constraints, four replicates were set up for the 1 and 25 mg a.s./kg dry soil treatment groups and eight replicates were set up for the control and the 5 mg a.s./dry soil treatments. Microarthropods were extracted from four representative soil subsamples (120 g of fresh soil each) from each cylinder using a Macfadyen high gradient extractor. Individuals of *E. fetida* were carefully collected from the soil by hand sorting. After extraction, all species were identified and counted under a binocular microscope.
Endpoints:	EC_{10} (extrapolated not measured), EC_{50}, population development (abundance).
Test concentrations:	Untreated control, three concentrations of alpha-cypermethrin: 1, 5, and 25 mg/kg dry soil.
Test conditions:	Each mesocosm was covered by a transparent plastic lid with holes for ventilation and stored at 15°C with a 12:12 h light-dark periodicity. Mesocosms were weighted and moisture was adjusted weekly by spraying water onto the soil surface in order to maintain water content of approximately 20%. Every week lost food was replenished, and moistened dried cattle manure (1:3 (*w:w*) manure:water) was added weekly on the surface of the soil in order to avoid food limitation.
Test soil:	Natural agricultural soil; sandy loam (38.0% coarse sand, 40.6% fine sand, 10.0% silt, 12.3% clay); 30% water holding capacity; pH 6.2.
Analytics:	PLFA (phospholipid fatty acid) analysis to determine main taxa for the soil microbial community. The total amount of PFLA was used as an estimator of the microbial biomass. GC-MS analyses to determine the concentration of alpha-cypermethrin in the soil after 8 weeks (20 subsamples of 5 g soil each) in both communities.
Statistics:	Descriptive statistics; mixed effect models; F-test; linear regression of log-transformed abundances of a species was used to estimate EC_{10} and EC values using the estimate function of SAS/PROC NLMIXED (SAS Institute Inc., 2011); quantitative PLFA data was analyzed using a GLM procedure to test for main effects and interactions, and Bonferroni post-test to compare effect of individual insecticide concentrations. Principal component analysis was performed on the data sets from the PLFA analysis using the Unscrambler software v. 7.6 (CAMO ASA, NO).

II. RESULTS AND DISCUSSION

The two different communities responded differently to the insecticide treatments. Alpha-cypermethrin had a general negative effect on the soil fauna, i.e. the soil non-target arthropod *Hypoaspis aculeifer and* the fresh body weight of *E. fetida*. The two different communities responded in a different manner to the insecticide. A positive effect due to the presence of the earthworms in the COM-F was observed, where in contrast the predator mite was more abundant in the COM-C.

Soil mites
The predatory mite *H. aculeifer* was significantly affected by the insecticide ($p < 0.001$), too.

Earthworms
No mortality of earthworms was observed in any of the test containers. The biomass of *E. fetida* increased with time at all alpha-cypermethrin concentrations. A negative effect at 5 and 25 mg a.s./kg dry soil was observed ($p < 0.05$). After eight weeks, the biomass was reduced by 16% at the highest tested concentration.

Soil microbial community
At week 4, the total PLFA content in soil was lower (varying from 10 to 100%) in the COM-C compared to COM-F, tending to decrease (not significantly) with increasing insecticide concentration. After 8 weeks, it was similar in the two communities and unaffected by the insecticide concentration. There were no systematic trends in relation to insecticide treatment (no significant main effect of insecticide concentration).

A summary of the results is presented in the table below.

Table 8.4.1-5: EC_{10} and the EC_{50} values of the tested species after week 4 and 8 *

Species	Time [week]	Community	EC_{10} [mg a.s./kg dry soil]	95% C.L	EC_{50} [mg a.s./kg dry soil]	95% C.L
Hypoaspis aculeifer	4	COM-C	2.7	1.2 – 4.2	13.4	5.8 – 21.1
	8	COM-C	0.5	0.3 – 0.7	3.2	1.7 – 4.7
	8	COM-F	2.8	0.1 – 5.5	14.1	0.6 – 27.6
Eisenia fetida	4	COM-F	4.8	1.6 – 7.9	23.8	8.2 – 39.5
	8	COM-F	11.5	2.0 – 21.0	> 25	--

* EC_{50} and EC_{10} values have been estimated only for significant declines of species abundances with alpha-cypermethrin concentration and similarly for the fresh body weight of *E. fetida*.
C.L. = Confidence limits.
COM-C = Community with *E. crypticus.*
COM-F = Community with *E. fetida.*

Table 8.4.1-6: Effect on individual species abundances in the mesocosms by the factors (time, community and alpha-cypermethrin) and interactions of those

Species	Time	COM	alpha-cypermethrin	Time*Conc.	COM*Conc.	Time* COM
Hypoaspis aculeifer		* ↓	* ↓		*	
Eisenia fetida	* ↑		* ↓	*		

COM: indicates community effect, COM-F vs. COM-C effect; Time: indicates different effects after 4 and 8 weeks; alpha-cypermethrin: Pesticide effect (Conc. 0, 1, 5, 25 mg/kg dry soil). Significance is indicated by:*: $P < 0.05$; **: $P < 0.01$. ↑ and ↓ indicate positive (↑) or negative effects (↓) driven by the factors on the population abundance.

III. CONCLUSION

The two different communities responded differently to the insecticide treatments. Alpha-cypermethrin had a negative effect on the soil non-target arthropod *Hypoaspis aculeifer and* the fresh body weight of *E. fetida*. A positive effect due to the presence of the earthworms in the COM-F was observed, where in contrast the predator mite was more abundant in the COM-C.

CA 8.4.2 Effects on non-target soil meso- and macrofauna (other than earthworms)

Report: CA 8.4.2/1
Friedrich S., 2014a
Effects of Reg.No. 130213 (metabolite of BAS 310 I, alpha-Cypermethrin, CL 206128) on the reproduction of the collembolan Folsomia candida
2014/1135435
Guidelines: OECD 232 (2009), ISO 11267 (1999)
GLP: yes
(certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) on mortality and reproduction of the collembolan, *Folsomia candida*, were investigated in a chronic laboratory experiment over a time period of 28 days. The test item was mixed into artificial soil at rates of 25, 50, 100, 200 and 400 mg CL 206128/kg dry soil. For the solvent control, the soil was left untreated. 4 replicates were prepared for the treatment groups and 8 replicates were prepared for the solvent control, each containing 10 springtails. Assessment of mortality and reproduction was made 28 days after treatment.

Statistically significant differences on mortality compared to the solvent control were observed at a concentration of 400 mg CL 206128/kg dry soil. Mortality rates of 0% - 50.0% were recorded in the test item treatment groups. 3.8% parental mortality was observed in the solvent control. Statistically significant differences compared to the solvent control on number of juveniles were recorded at a concentration of 400 mg CL 206128/kg dry soil. The mean reproduction in the solvent control reached 659 juveniles. Reproduction rates in 25, 50, 100, 200 and 400 mg CL 206128/kg dry soil were 642, 664, 669, 583 and 473 juveniles, respectively.

In a 28-day collembolan reproduction study with Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) the NOEC based on mortality and reproduction was determined to be 200 mg/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128), batch No.: AC12251-34, analyzed purity: 100% (tolerance ± 1.0%)

B. STUDY DESIGN

Test species: Collembola (*Folsomia candida*), age: 9 - 12 days; source: in-house culture.

Test design: 28-day test in treated artificial soil (with 5% peat); different concentrations of the test item were mixed homogeneously into the soil which was filled in glass vessels before collembolans were introduced on top of the soil. 6 treatment groups (5 test item concentrations, solvent control) were set up with 4 replicates for the test item treatments and 8 replicates for the solvent control and each containing 10 juvenile collembolans. Feeding of collembola with about 2 mg dry yeast at the beginning of the test for each test vessel and additional feeding on day 14. Assessment of adult collembolans mortality, reproduction rate (number of juveniles) and behavioral effects was carried out after 28 days.

Endpoints: Mortality and reproduction rate after 28 days.

Reference item: Boric acid (100% analyzed). The effects of the reference item were investigated in a separate study.

Test concentrations: Control, 25, 50, 100, 200 and 400 mg CL 206128/kg dry soil.

Test conditions: Artificial soil according to OECD 232 with a peat content of 5%; water content: 58.5% of the maximum water holding capacity (WHC) at test initiation and 57.4% - 57.8% of the maximum WHC at test termination; pH 6.00 - 6.12 at test initiation, pH 5.65 - 5.74 at test termination; temperature 18.1°C - 19.3°C; photoperiod: 16 h light : 8 h dark; light intensity 520 lux.

Statistics: Descriptive statistics. Fisher's Exact Binominal test with Bonferroni Correction for mortality ($\alpha = 0.05$, one-sided greater), Williams-t-test for reproduction ($\alpha = 0.05$, one-sided smaller).

II. RESULTS AND DISCUSSION

Statistically significant differences on mortality compared to the solvent control were observed at a concentration of 400 mg CL 206128/kg dry soil (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha = 0.05$, one-sided greater). Mortality rates of 0% - 50.0% were recorded in the test item treatment groups. 3.8% parental mortality was observed in the solvent control. Statistically significant differences compared to the solvent control on number of juveniles were recorded at a concentration of 400 mg CL 206128/kg dry soil (Williams-t-test, $\alpha = 0.05$, one-sided smaller). The mean reproduction in the solvent control reached 659 juveniles. Reproduction rates in 25, 50, 100, 200 and 400 mg CL 206128/kg dry soil were 642, 664, 669, 583 and 473 juveniles, respectively. The results are summarized in Table 8.4.2-1.

Table 8.4.2-1: Effects of Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) on collembola (*Folsomia candida*) in a 28-day reproduction study

CL 206128 [mg/kg dry soil]	Solvent control	25	50	100	200	400
Mortality (day 28) [%]	3.8	5.0	5.0	0.0	5.0	50.0 *

III. CONCLUSION

In a 28-day collembolan reproduction study with Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) the NOEC based on mortality and reproduction was determined to be 200 mg/kg dry soil.

Report:	CA 8.4.2/2 Friedrich S., 2015a Effects of Reg. No. 4080830 (metabolite of BAS 310 I, Alpha-Cypermethrin, CL 912554) on the reproduction of the collembolan Folsomia candida 2014/1135436
Guidelines:	OECD 232 (2009), ISO 11267 (1999)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of Reg. No. 4080830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554) on mortality and reproduction of the collembola, *Folsomia candida*, were investigated in a chronic laboratory experiment over a time period of 28 days. The test item was mixed into artificial soil at rates of 0.25, 0.5, 1.0, 2.0, 4.0 and 8.0 mg CL 912554/kg dry soil. For the solvent control, the soil was left untreated. 4 replicates were prepared for the treatment groups and 8 replicates were prepared for the solvent control, each containing 10 springtails. Assessment of mortality and reproduction was made 28 days after treatment.

No statistically significant effect on parental mortality was found for any concentration tested. Mortality rates of 2.5% - 5.0% were recorded in the test item treatment groups. In the solvent control the mortality rate was 2.5%. No statistically significant effects on the number of juveniles compared to the solvent control were recorded at any concentration tested. The mean reproduction in the solvent control reached 951 juveniles. Reproduction rates in 0.25, 0.5, 1.0, 2.0, 4.0 and 8.0 mg CL 912554/kg dry soil were 943, 920, 946, 907, 950 and 880 juveniles, respectively.

In a 28-day collembolan reproduction study with Reg. No. 4080830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554) the NOEC based on mortality and reproduction was determined to be ≥ 8.0 mg/kg dry soil.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 4080830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554), batch No.: AC12717-65, analyzed purity: 99.5% (tolerance ± 1.0%)

B. STUDY DESIGN

Test species: Collembola (*Folsomia candida*), age: 9 - 12 days; source: in-house culture.

Test design: 28-day test in treated artificial soil (with 5% peat); different concentrations of the test item were mixed homogeneously into the soil which was filled in glass vessels before collembolans were introduced on top of the soil. 7 treatment groups (6 test item concentrations, solvent control) were set up with 4 replicates for the test item treatments and 8 replicates for the solvent control and each containing 10 juvenile collembolans. Feeding of collembola with about 2 mg dry yeast at the beginning of the test for each test vessel and on day 14. Assessment of adult mortality, reproduction rate (number of juveniles) and behavioral effects was carried out after 28 days.

Endpoints: Mortality and reproduction rate after 28 days.

Reference item: Boric acid (100% analyzed). The effects of the reference item were investigated in a separate study.

Test concentrations: Control, 0.25, 0.5, 1.0, 2.0, 4.0 and 8.0 mg CL 912554/kg dry soil.

Test conditions: Artificial soil according to OECD 232 with a peat content of 5%; water content: 58.3% - 58.8% of the maximum water holding capacity (WHC) at test initiation and 57.1% - 58.1% of the maximum WHC at test termination; pH 6.05 - 6.11 at test initiation, pH 5.72 - 5.75 at test termination; temperature 18.5°C - 21.8°C; photoperiod: 16 h light : 8 h dark; light intensity 460 lux.

Statistics: Descriptive statistics. Fisher's Exact Binominal test with Bonferroni Correction for mortality ($\alpha = 0.05$, one-sided greater), Williams-t-test for reproduction ($\alpha = 0.05$, one-sided smaller).

II. RESULTS AND DISCUSSION

No statistically significant effect (Fisher's Exact Binomial Test with Bonferroni Correction, α = 0.05, one-sided greater) on parental mortality was found for any concentration tested. Mortality rates of 2.5% - 5.0% were recorded in the test item treatment groups. In the solvent control the mortality rate was 2.5%. No statistically significant effects (Williams-t-test, α = 0.05, one-sided smaller) on the number of juveniles compared to the solvent control were recorded at any concentration tested. The mean reproduction in the solvent control reached 951 juveniles. Reproduction rates in 0.25, 0.5, 1.0, 2.0, 4.0 and 8.0 mg CL 912554/kg dry soil were 943, 920, 946, 907, 950 and 880 juveniles, respectively. The results are summarized in Table 8.4.2-1.

III. CONCLUSION

In a 28-day collembolan reproduction study with Reg. No. 4080830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554) the NOEC based on mortality and reproduction was determined to be ≥ 8.0 mg/kg dry soil.

Report:	CA 8.4.2/3 Schulz L., 2014a Effects of Reg.No. 130213 (metabolite of BAS 310 I, alpha-Cypermethrin, CL 206128) on the reproduction of the predatory mite Hypoaspis aculeifer 2014/1135437
Guidelines:	OECD 226 (2008)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) on mortality and reproduction of the predatory mite *Hypoaspis aculeifer* were investigated in a chronic laboratory study over a time period of 14 days. The test item was mixed into artificial soil at concentrations of 62.5, 125, 250, 500 and 1000 mg/kg dry soil. For the control treatment, the soil was prepared with acetone (solvent control). 8 replicates and 4 replicates were prepared for the solvent control and test item treatment groups, respectively, each containing 10 adult predatory mites (females). Assessment of mortality and reproduction was carried out after the 14-day exposure of the predatory mites.

Mortality rates of 0.0 - 7.5% were recorded in the test item treatment groups. In the solvent control the mortality rate was 0.0%. The observed mortality rates for adults mortality in the test item treatment groups compared to the control were not statistically significantly different. Differences between the behavior and the morphology of the mites in the solvent control and the test item treatment groups were not observed. Reproduction rates in the 62.5, 125, 250, 500 and 1000 mg/kg dry soil were 240.3, 252.3, 239.8, 229.3 and 248.0 juveniles, respectively. The mean reproduction in the solvent control reached 243.0 juveniles. The test item showed no statistically significantly adverse effects on reproduction at all tested concentrations compared to the control.

In a 14-day *Hypoaspis aculeifer* reproduction study with Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128), the LC_{50} and the EC_{50} were estimated to be higher than 1000 mg/kg dry soil. The NOEC for mortality and for reproduction was determined to be ≥ 1000 mg/kg dry soil, the highest concentration tested.

A. MATERIALS

Test item: Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128), batch No.: AC12251-34, analyzed purity: 100.0% (tolerance ± 1.0%).

B. STUDY DESIGN

Test species: *Hypoaspis aculeifer* (Canestrini), adult mites with an age difference of 2 days; source: in-house culture.

Test design: The effects of Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128) on mortality and reproduction of the predatory mite *Hypoaspis aculeifer* were investigated in a chronic laboratory study over a time period of 14 days according to OECD 226 (2008). The different concentrations of the test item were homogeneously mixed into the artificial soil which was then used to fill glass vessels after which the predatory mites were introduced on top of the soil; 6 treatment groups (5 test item concentrations, solvent control); 8 replicates for the solvent control group and 4 replicates for the test item treatment groups each with 10 predatory mites. Feeding of mites with *Tyrophagus putrescentiae* at the beginning and *ad libitum* during the test. Assessment of adult mortality and reproduction effects was carried out after 14 days.

Endpoints: Mortality and reproduction rate after 14 days.

Reference item: Dimethoate (analyzed purity: 99.8%, tolerance ± 1.0%). The effects of the reference item were investigated in a separate study.

Test concentrations: Control, test item: 62.5, 125, 250, 500 and 1000 mg/kg dry soil.

Test conditions: Artificial soil according to OECD 226, pH 5.5 - 6.0 at test initiation, pH 5.5 - 5.8 at test termination; water content at test initiation 48.04 - 50.83% of maximum water holding capacity (WHC) and 45.45 - 48.42% of maximum WHC at test termination; temperature 19.7 - 21.1°C; photoperiod: 16 h light : 8 h dark; light intensity: 504 lux.

Statistics: Fisher's Exact Binomial Test with Bonferroni Correction for mortality ($\alpha = 0.05$, one-sided greater), Dunnett-t-test for reproduction ($\alpha = 0.05$, one-sided smaller).

II. RESULTS AND DISCUSSION

Mortality rates of 0.0 - 7.5% were recorded in the test item treatment groups. In the solvent control the mortality rate was 0.0%. The observed mortality rates for adults mortality in the test item treatment groups compared to the control were not statistically significantly different (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha = 0.05$, one-sided greater). Differences between the behavior and the morphology of the mites in the solvent control and the test item treatment groups were not observed.

Reproduction rates in the 62.5, 125, 250, 500 and 1000 mg/kg dry soil were 240.3, 252.3, 239.8, 229.3 and 248.0 juveniles, respectively. The mean reproduction in the solvent control reached 243.0 juveniles. The test item showed no statistically significantly adverse effects on reproduction at all tested concentrations compared to the control (Dunnett-t-test, $\alpha = 0.05$, one-sided smaller). The results are summarized in Table 8.4.2-3.

Table 8.4.2-3: Effects of CL 206128 on *Hypoaspis aculeifer* mortality and reproduction (14 days)

CL 206128 [mg/kg dry soil]	**Control**	**62.5**	**125**	**250**	**500**	**1000**
Mortality [%]	0.0	0.0	2.5	2.5	7.5	0.0
No. of juveniles (day 14)	243.0	240.3	252.3	239.8	229.3	248.0
Reproduction (day 14) [% of control]	100	99	104	99	94	102
Endpoints [mg/kg dry soil]						
NOEC (mortality)	≥ 1000					
NOEC (reproduction)	≥ 1000					
LC_{50}[1)]	> 1000					
EC_{50}[1)]	> 1000					

1) Based on estimation of the data.

In a separate study the EC_{50} (reproduction) of the reference item dimethoate (analyzed purity: 99.8%, tolerance ± 1.0%) was calculated to be 6.2 mg/kg dry soil.

III. CONCLUSION

In a 14-day *Hypoaspis aculeifer* reproduction study with Reg. No. 130 213 (metabolite of BAS 310 I, alpha-cypermethrin, CL 206128), the LC_{50} and the EC_{50} were estimated to be higher than 1000 mg/kg dry soil. The NOEC for mortality and for reproduction was determined to be ≥ 1000 mg/kg dry soil, the highest concentration tested.

Report:	CA 8.4.2/4 Schulz L., 2014b Effects of Reg.No. 4080830 (metabolite of BAS 310 I, alpha-Cypermethrin, CL 912554) on the reproduction of the predatory mite Hypoaspis aculeifer 2014/1135438
Guidelines:	OECD 226 (2008)
GLP:	yes (certified by Saechsisches Staatsministerium fuer Umwelt und Landwirtschaft, Dresden, Germany)

Executive Summary

The effects of Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554) on mortality and reproduction of the predatory mite *Hypoaspis aculeifer* were investigated in a chronic laboratory study over a time period of 14 days. The test item was mixed into artificial soil at concentrations of 31.25, 62.5, 125, 250 and 500 mg/kg dry soil. For the control treatment, the soil was prepared with acetone (solvent control). 8 replicates and 4 replicates were prepared for the solvent control and test item treatment groups, respectively, each containing 10 adult predatory mites (females). Assessment of mortality and reproduction was carried out after the 14-day exposure of the predatory mites.

Mortality rates of 2.5 - 12.5% were recorded in the test item treatment groups. In the solvent control the mortality rate was 2.5%. The observed mortality rates for adults mortality in the test item treatment groups compared to the control were not statistically significantly different. Differences between the behavior and the morphology of the mites in the solvent control and the test item treatment groups were not observed. Reproduction rates in the concentrations of 31.25, 62.5, 125, 250 and 500 mg/kg dry soil were 183.8, 207.8, 176.0, 156.0 and 107.5 juveniles, respectively. The mean reproduction in the solvent control reached 199.5 juveniles. The test item showed no statistically significantly adverse effects on reproduction up to and including 125 mg/kg dry soil. However, CL 912554 caused statistically significant effects on reproduction at 250 and 500 mg/kg dry soil.

In a 14-day *Hypoaspis aculeifer* reproduction study with Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554), the LC_{50} and the EC_{50} were estimated to be higher than 500 mg/kg dry soil, the highest concentration tested. The NOEC for mortality and for reproduction were determined to be ≥ 500 mg/kg dry soil and 125 mg/kg dry soil, respectively.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554), batch No.: AC12717-65, analyzed purity: 99.5% (tolerance ± 1.0%).

B. STUDY DESIGN

Test species: *Hypoaspis aculeifer* (Canestrini), adult mites with an age difference of 2 days; source: in-house culture.

Test design: The effects of Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554) on mortality and reproduction of the predatory mite species *Hypoaspis aculeifer* were investigated in a chronic laboratory study over a time period of 14 days according to OECD 226 (2008).
The different concentrations of the test item were homogeneously mixed into the artificial soil which was then used to fill glass vessels after which the predatory mites were introduced on top of the soil; 6 treatment groups (5 test item concentrations, solvent control); 8 replicates for the solvent control group and 4 replicates for the test item treatment group each with 10 predatory mites. Feeding of mites with *Tyrophagus putrescentiae* at the beginning and *ad libitum* during the test. Assessment of adult mortality and reproduction effects was carried out after 14 days.

Endpoints: Mortality and reproduction rate after 14 days.

Reference item: Dimethoate (analyzed purity: 99.8%, tolerance ± 1.0%). The effects of the reference item were investigated in a separate study.

Test concentrations: Control, 31.25, 62.5, 125, 250 and 500 mg/kg dry soil.

Test conditions: Artificial soil according to OECD 226, pH 5.5 - 5.7 at test initiation, pH 5.5 - 5.6 at test termination; water content at test initiation 48.91 - 52.42% of maximum water holding capacity (WHC) and 48.11 - 49.83% of maximum WHC at test termination; temperature 19.7 - 20.7°C; photoperiod: 16 h light : 8 h dark; light intensity: 520 lux.

Statistics: Fisher's Exact Binomial Test with Bonferroni Correction for mortality ($\alpha = 0.05$, one-sided greater), Williams-t-test for reproduction ($\alpha = 0.05$, one-sided smaller), Probit analysis for EC_x estimation.

II. RESULTS AND DISCUSSION

Mortality rates of 2.5 - 12.5% were recorded in the test item treatment groups. In the solvent control the mortality rate was 2.5%. The observed mortality rates for adults mortality in the test item treatment groups compared to the control were not statistically significantly different (Fisher's Exact Binomial Test with Bonferroni Correction, $\alpha = 0.05$, one-sided greater). Differences between the behavior and the morphology of the mites in the solvent control and the test item treatment groups were not observed.

Reproduction rates in the concentrations of 31.25, 62.5, 125, 250 and 500 mg/kg dry soil were 183.8, 207.8, 176.0, 156.0 and 107.5 juveniles, respectively. The mean reproduction in the solvent control reached 199.5 juveniles. The test item showed no statistically significantly adverse effects on reproduction up to and including 125 mg/kg dry soil. However, CL 912554 caused statistically significant effects on reproduction at 250 and 500 mg/kg dry soil (Williams-t-test, $\alpha = 0.05$, one-sided smaller). The results are summarized in Table 8.4.2-4.

Table 8.4.2-4: Effects of CL 912554 on *Hypoaspis aculeifer* mortality and reproduction (14 days)

CL 912554 [mg/kg dry soil]	**Control**	**31.25**	**62.5**	**125**	**250**	**500**
Mortality [%]	2.5	2.5	5.0	5.0	12.5	5.0
No. of juveniles (day 14)	199.5	183.8	207.8	176.0	156.0 *	107.5 *
Reproduction (day 14) [% of control]	100	92	104	88	78	54
Endpoints [mg/kg dry soil]						
NOEC (mortality)	≥ 500					
NOEC (reproduction)	125					
LC_{50} [1)]	> 500					
EC_{50} [1)]	> 500					

* Statistically significantly different compared to the control (Williams-t-test, $\alpha = 0.05$, one-sided smaller).
1) Based on estimation of the data.

In a separate study the EC_{50} (reproduction) of the reference item dimethoate (analyzed purity: 99.8%, tolerance ± 1.0%) was calculated to be 6.2 mg/kg dry soil.

III. CONCLUSION

In a 14-day *Hypoaspis aculeifer* reproduction study with Reg. No. 4 080 830 (metabolite of BAS 310 I, alpha-cypermethrin, CL 912554), the LC_{50} and the EC_{50} were estimated to be higher than 500 mg/kg dry soil, the highest concentration tested. The NOEC for mortality and for reproduction were determined to be ≥ 500 mg/kg dry soil and 125 mg/kg dry soil, respectively.

CA 8.4.2.1 Species level testing

Not triggered; no new studies are available.

From the performed literature search, two peer-reviewed scientific studies on non-target soil invertebrates were considered relevant and reliable (with restrictions; RI 2) for the terrestrial risk assessment of alpha-cypermethrin. Please refer to chapter CA 8.4.1 for details.

CA 8.5 Effects on nitrogen transformation

Guidelines:	OECD 216 (2000)
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

The effect of BAS°310 I on nitrogen transformation was tested in a lucerne-enriched silty sand soil. BAS°310 I was applied to samples of the soil in a laboratory at test concentrations of 1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil. The treated soils and untreated control were incubated at 20 ± 2 °C in the dark for 28 days. Triplicate samples of each treatment were removed for analysis of NH_4-nitrogen and NO_3-nitrogen 0, 7, 14 and 28 days after application.

No adverse effects of BAS°310°I on nitrogen transformation could be observed at all test item concentrations (1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil) after 28 days. Only slight deviations from the control between + 0.728% and + 4.95% were measured after 28 days.

Based on the results of this study, BAS°310°I caused no adverse effects (< 25% deviation from control according to OECD 216) on the soil nitrogen transformation (measured as NO_3-N production) in silty sand soil tested at concentrations up to 100 mg a.s./kg dry soil after 28 days of incubation.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 310 I, batch no. COD-000166, content: alpha-cypermethrin (BAS°310°I, Reg. No. 4 078 193), purity: 99.3% (w/w).

B. STUDY DESIGN

Test soil: Biologically active agricultural soil: silty sand soil, pH 6.75, 1.17% C_{org}, WHC: 27.3%.

Test design: Determination of the N-transformation (NO_3-nitrogen production) in soil enriched with lucerne meal (concentration in soil 0.5%). Comparison of test item treated soil with a non-treated soil. NH_4-nitrogen formed from organically bound nitrogen and NO_3-nitrogen formed from the nitrification process were determined using an Ionanalyser (Orion Research Inc). Sampling scheme: 0, 7, 14 and 28 days after treatment. Sub-samples (3 replicates) were withdrawn from the bulk batches and subjected to the measurement.

Endpoints: Effects on the NO_3-nitrogen production 0, 7, 14 and 28 days after application.

Test concentrations: Control, 1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil; test concentrations related to a soil depth of 5 cm and a soil density of 1.5 g/cm^3.

Reference item: Dinoterb (purity: 97.5%). The reference item was tested at 13.3 mg/kg dry soil in a separate study.

Test conditions: Soil moisture: approx. 45 % of maximum water holding capacity, water content: 11.1 %, pH 6.75. Soil samples were incubated at 20 ± 2 °C while stored in glass bottles in the dark.

Statistics: Descriptive statistics. Dunnett's t-Test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

No adverse effects of BAS°310°I on nitrogen transformation could be observed at all test item concentrations (1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil) after 28 days. Only slight deviations from the control between + 0.728% and + 4.95% were measured after 28 days. Effects in all test concentrations were not statistically significantly different compared to the control (Dunnett's t-Test; $\alpha = 0.05$). The results are summarized below in Table 8.5-2.

Table 8.5-2: Effects of BAS°310°I on soil micro-organisms (nitrogen transformation) on days 7, 14 and 28 of incubation

Soil (days)	Control	1.0 mg BAS°310°I/kg dry soil		3.3 mg BAS°310°I/kg dry soil		10 mg BAS°310°I/kg dry soil		33 mg BAS°310°I/kg dry soil		100 mg BAS°310°I/kg dry soil	
	NO_3-N [mg/kg dry soil	NO_3-N [mg/kg dry soil]	% Deviation from control [1)]	NO_3-N [mg/kg dry soil]	% Deviation from control [1)]	NO_3-N [mg/kg dry soil]	% Deviation from control [1)]	NO_3-N [mg/kg dry soil]	% Deviation from control [1)]	NO_3-N [mg/kg dry soil]	% Deviation from control [1)]
Silty sand soil (7 d)	32.5	32.1	-1.07	33.2	+2.06	31.5	-2.93	31.4	-3.32	33.0	+1.67
Silty sand soil (14 d)	41.4	43.7	+5.66	43.8	+5.82	42.5	+2.58	42.9	+3.70	40.5	-2.09
Silty sand soil (28 d)	43.5	45.4	+4.22	43.8	+0.728	45.7	+4.95	45.1	+3.55	45.5	+4.47

[1)] Based on NO_3-nitrogen production; - = inhibition, + = stimulation.

The reference item Dinoterb produced a stimulation of nitrogen transformation of +34.7% at 13.3 mg/kg dry soil after 28 days incubation.

III. CONCLUSION

Based on the results of this study, BAS°310°I caused no adverse effects (< 25% deviation from control according to OECD 216) on the soil nitrogen transformation (measured as NO_3-N production) in silty sand soil tested at concentrations up to 100 mg a.s./kg dry soil after 28 days of incubation.

Report:	CA 8.7/1 Koelzer U., 2006b Effects of BAS 310 I (Reg.No. 4078193) on the activity of the soil microflora - Carbon transformation test (ECx) 2006/1008041
Guidelines:	OECD 217 (2000)
GLP:	yes (certified by Ministerium fuer Umwelt und Verkehr Baden-Wuerttemberg, Stuttgart)

Executive Summary

The effect of BAS°310 I on carbon transformation was tested in a silty sand soil. BAS°310 I was applied to samples of the soil in a laboratory at test concentrations of 1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil. The treated soils and untreated control were incubated at 20 ± 2 °C in the dark for 28 days. Triplicate samples of each treatment were removed for analysis of carbon transformation (oxygen consumption) 0, 7, 14, 28 and 56 days after application.

No adverse effects of BAS°310°I on carbon transformation could be observed at all test item concentrations (1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil) after 28 days. An additional measurement after 56 days confirmed that result. Only slight deviations from the control between -1.37% and -10.1% were measured after 56 days.

Based on the results of this study, BAS°310°I caused no adverse effects (< 25% deviation from control according to OECD 217) on the soil carbon transformation (measured as oxygen consumption) in silty sand soil tested at concentrations up to 100 mg a.s./kg dry soil after 28 days of incubation. An additional measurement after 56 days confirmed that result.

I. MATERIAL AND METHODS

A. MATERIALS

Test item: BAS 310 I, batch no. COD-000166, content: alpha-cypermethrin (BAS°310°I, Reg. No. 4 078 193), purity: 99.3% (w/w).

B. STUDY DESIGN

Test soil:	Biologically active agricultural soil: silty sand soil, pH 6.75, 1.17% C_{org}, WHC: 27.3%.
Test design:	Determination of carbon transformation in soil after addition of glucose (concentration in soil 0.3%). Comparison of test item treated soil with a non-treated soil. A "OxiTop Control®" system was used to measure the oxygen consumption over a period of maximum 24 hours at different sampling intervals. Sampling scheme: 0, 7, 14, 28 and 56 days after treatment, sub-samples were withdrawn from the bulk batches and subjected to the measurement.
Endpoints:	Effects on O_2 consumption 0, 7, 14, 28 and 56 days after application.
Test concentrations:	Control, 1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil; test concentrations related to a soil depth of 5 cm and a soil density of 1.5 g/cm^3.
Reference item:	Dinoterb (purity: 97.5%). The reference item was tested at 13.3 mg/kg dry soil in a separate study.
Test conditions:	Soil moisture: approx. 45% of maximum water holding capacity, water content: 11.4%; pH 6.75. Soil samples were incubated at 20 ± 2 °C while stored in glass bottles in the dark.
Statistics:	Descriptive statistics. Multiple-t-test, Dunnett's t-Test ($\alpha = 0.05$).

II. RESULTS AND DISCUSSION

No adverse effects of BAS°310°I on carbon transformation could be observed at all test item concentrations (1.0, 3.3, 10, 33 and 100 mg BAS°310°I/kg dry soil) after 28 days. An additional measurement after 56 days confirmed that result. Only slight deviations from the control between -1.37% and -10.1% were measured after 56 days. Effects of all test concentrations were not statistically significantly different compared to the control (Multiple-t-test, Dunnett's t-Test; $\alpha = 0.05$). The results are summarized below in Table 8.7-1.

Table 8.7-1: Effects of BAS°310°I on soil micro-organisms (carbon transformation) on days 7, 14 and 28 and 56 of incubation

Soil (days)	Control	1.0 mg BAS°310°I/kg dry soil		3.3 mg BAS°310°I/kg dry soil		10 mg BAS°310°I/kg dry soil		33 mg BAS°310°I/kg dry soil		100 mg BAS°310°I/kg dry soil	
	O_2 consumption [mg/h/kg dry soil]	O_2 consumption [mg/h/kg dry soil]	% Deviation from control [1)]	O_2 consumption [mg/h/kg dry soil]	% Deviation from control [1)]	O_2 consumption [mg/h/kg dry soil]	% Deviation from control [1)]	O_2 consumption [mg/h/kg dry soil]	% Deviation from control [1)]	O_2 consumption [mg/h/kg dry soil]	% Deviation from control [1)]
Silty sand soil (7 d)	4.84	4.19	-13.4	3.70	-23.6	4.44	-8.35	4.24	-12.5	3.38	-30.2
Silty sand soil (14 d)	4.28	4.56	+6.40	3.85	-10.1	4.72	+10.3	4.08	-4.82	4.18	-2.30
Silty sand soil (28 d)	3.77	4.38	+16.1	3.94	+4.38	4.31	+14.1	3.30	-12.6	3.89	+3.15
Silty sand soil (56 d)	4.68	4.25	-9.13	4.43	-5.27	4.62	-1.37	4.21	-10.1	4.61	-1.50

[1)] Based on O_2 consumtion; - = inhibition, + = stimulation.

The reference item Dinoterb produced an inhibition of carbon transformation of 35.1% at 13.3 mg/kg dry soil after 28 days incubation.

III. CONCLUSION

Based on the results of this study, BAS°310°I caused no adverse effects (< 25% deviation from control according to OECD 217) on the soil carbon transformation (measured as oxygen consumption) in silty sand soil tested at concentrations up to 100 mg a.s./kg dry soil after 28 days of incubation. An additional measurement after 56 days confirmed that result.

CA 8.8 Effects on biological methods for sewage treatment

The results of the already peer-reviewed and accepted study are still valid and they are summarized in Table 8.8-1. No new study has been performed.

Table 8.8-1: Effects on biological methods for sewage treatment

Test item	Study type	Endpoint [mg a.s./L]	Reference (BASF DocID)	EU agreed
BAS 310 I (alpha-cypermethrin)	Respiration inhibition test (inhibition of oxygen consumption activated sludge from wastewater plant)	No inhibitory effect on microbial respiration up to 1000 mg a.s./L	AL-123-092 amended by AL-690-005	yes

CA 8.9 Monitoring data

According to the knowledge of the applicant, there are currently no published ecotoxicological monitoring data available for alpha-cypermethrin or its metabolites, which would provide additional knowledge on the ecotoxicological assessment not covered by this dossier.

CA 9 LITERATURE DATA

A literature search on alpha-cypermethrin and the common product trade names was performed by the BASF Group Information Center. The Literature Search Report on alpha-cypermethrin describes the general search and evaluation process as well as details on search profiles, search histories and summary tables.

The complete search report is provided in K-CA 9 (BASF DocID 2014/1320877).

The first step of the search result processing based on summary records was done by the Information Center and involved the separation into "hits" and "ballast" (obviously irrelevant records). The “ballast” was not further processed.

The “hits” were further evaluated by the scientific experts and categorized into “not relevant”, “not reliable”, and “used for dossier”. This is documented in EXCEL files which are attached to the search report in K-CA 9 with the file names as listed below (alphabetical order):

	Alpha-cypermethrin Literature Metabolism and Residues in Plants
Toxicology:	Alpha-cypermethrin Literature Toxicology

The hits in “Alpha-cypermethrin Literature Analytics and Product Chemistry”, did not contribute to the risk assessment as no literature was identified as either relevant or reliable for further evaluation; no new endpoints or new relevant analytical residue methods have been identified. Hence, none were therefore further discussed in the dossier.

The hits in “E-fate" did not contribute to the risk assessment, but three publications were further discussed in the dossier as supportive information.

The hits in “Metabolism and Residues in Animals”, “Metabolism and Residues in Plants”, “Ecotox general “, “Ecotox wildlife “, did not contribute to the risk assessment and were therefore not further discussed in the dossier.

CA 10 CLASSIFICATION AND LABELLING OF THE ACTIVE SUBSTANCE

The following harmonized classification and labelling was adopted for alpha-cypermethrin:

Legislation	Classification	Labelling	Concentration limits
Regulation (EC) No 1272/2008	Hazard class and category code: Acute Tox. 3 (oral) STOT SE 3 STOT RE 2 Aquatic Acute 1 Aquatic Chronic 1 Hazard statement code: H301, H335, H373, H400, H410	Pictogram signal word code: GHS06 GHS08 GHS09 Danger Hazard statement code: H301, H335, H373, H410	M-factor = 1000

New studies were performed leading to a change of classification for acute inhalation toxicity. Therefore, BASF proposed the following classification and labelling for alpha-cypermethrin:

Legislation	Classification	Labelling	Concentration limits
Regulation (EC) No 1272/2008	Hazard class and category code: Acute Tox. 3 (oral) **Acute Tox. 4 (inhalation)** STOT SE 3 STOT RE 2 Aquatic Acute 1 Aquatic Chronic 1 Hazard statement code: H301, **H332,** H335, H373, H400, H410	Pictogram signal word code: GHS06 GHS08 GHS09 Danger Hazard statement code: H301, **H332,** H335, H373, H410	M-factor = 1000
